'Descent from the Cross' in the Antwerp Museum, 'Mary Magdalen' in Lord Methuen's gallery at Corsham House, and a 'Madonna' at Berlin, while other specimens occur in the collections at Vienna, Munich, Frankfurt, and Dresden. The 'Two Misers' at Windsor has been of late years ascribed to his son Johann. M. died at Antwerp in 1531. See Van Even's *Recherches sur Quentin Messis* (Louvain, 1864).

Matt'er, in philosophy, is a term used to denote the unknown substratum underlying all phenomena revealed to us by consciousness. Our knowledge of it is only relative; we perceive by the senses only extension, figure, colour, &c., but in order to account for their existence assume these to be qualities of a hypothetical substance.

M., in physics, may be defined as that which fills space. It is the vehicle by which the energy of the universe is made evident and utilised. Its objective existence we assume not merely because it is an experience common to all, but because, subject it to any operation whatever, it cannot be increased or diminished in quantity. It is this principle of the noncreatability and indestructibility of M. upon which the whole science of chemistry is based; just as natural philosophy is based upon the same conservation principle applied to energy. M., as known to us, exists in three modifications—solid, liquid, and gaseous; and, according to the present theory of the ultimate nature of matter, these depend upon the arrangement of the molecules. A molecule is a group of atoms, held together by what are known as molecular forces; and atoms are the ultimate indivisible particles which compose matter. The nature of these atoms, whether they are the hard, rigid, incompressible spheres of the ancient atomists, or the pliable, vibrating, but yet unapproachable vortex rings of Sir W. Thomson, we cannot at present hope to determine, but experiment furnishes us with means to measure approximately the size of the molecules. The recent development by Clausius and Clerk Maxwell of the kinetic theory of gases has further given much insight into the probable nature of these ultimate particles. The various properties of matter are indicated under such articles as FLUIDS, GASES, SOLIDS, ELECTRICITY, ENERGY, HEAT, LIGHT, SOUND, SPACE, &c.

M. Erhorn, The ('the mount of the meadow'), or **Monte Cervino**, a famous needle-shaped peak to the W. of Monte Rosa on the border line between Italy and Switzerland. It is 14,780 feet high, and is difficult and dangerous of ascent.

Matthew, St., the son of Alphaeus, was called by Christ from his occupation of publican, or farmer of the Roman taxes, at Capernaum, to be a disciple (Matt. ix. 9), and became afterwards one of the twelve apostles, and, as is supposed, the author of a Gospel or life of Christ. Before his call he seems to have borne the name of Levi (cf. Mark ii. 13, 14; Luke v. 27, 28). Nothing is recorded of him in the New Testament after the Ascension of Christ. According to various traditions preserved by Church historians, he preached in Judæa, in Ethiopia, in Macedonia, and among the Persians, the Medes, and the Parthians. A late tradition says he suffered martyrdom. The Gospel of St. M. was probably written in Palestine, for Jewish Christians, between A.D. 60 and A.D. 70. Whether it was originally written in Greek, like the other Gospels, or in Aramaic, the vernacular of Palestine at the time (see JEWS, *Language and Literature*), is a point which is much debated among critics.

Matthew of Westminster, an English chronicler who flourished some time in the 14th c. All that is known of him is that he was a Benedictine monk of Westminster. His work, which bears the same title as Roger of Wendover's, viz., *Floris Historiarum*, goes over the same ground in the earlier part, but comes down to the death of Edward I., and for the last seventy years may be considered an original and important record. M. is a vivid narrator, and his work is particularly minute for the period after the Norman Conquest. The first printed edition appeared at London in 1567; the second at Frankfurt in 1601. There is an English translation in Bohn's Antiquarian Library.

• **Matthew Paris**, one of the most valuable chroniclers of the middle ages, was born about 1195, entered the Benedictine monastery of St. Alban's, of which he was chosen annalist in 1235, and died in 1259. The name Paris is thought by some to be derived from the city where he may have studied. M.'s chief

work, entitled by himself *Historia Major*, is a history of the world from its creation to the year of the author's death. Up to 1235 A.D. it is simply a transcript of Roger of Wendover's *Floris Historiarum*, with a few variations and additions, but the remainder is a copious and careful record of the events that happened in M.'s own lifetime, and is the work of a man of veracity, frankness, insight, and courage. It was first printed by Archbishop Parker in 1571. The latest edition is that of 1684. There is an English translation in Bohn's Antiquarian Library. Other works of M.'s are *Duorum Offarum Merciorum Regum Vita*, and *Vigina Abbatum S. Albani Vita*.

Matt'o-Grosso ('great wood'), the largest and westmost province of Brazil, bounded N. by Amazonas and Pará, E. by Goyaz, São, and Paulo, and S.W. by Paraguay and Bolivia. Area, 865,800 sq. miles; estimated pop. 46,000 (nine-tenths Indians and negroes). Forests cover a great part of the surface, which is crossed from E. to W. by a mountain range, from which valleys slope to the plains of the Amazon and Rio de la Plata. Cattle-rearing is the chief pursuit of the people. Gold, diamonds, and iron are found. Cuyaba (q. v.) is the chief town.—**M.-G.**, on the Guapore, 425 miles N.E. of Chuquisaca, founded in 1734, was in 1818 the chief town, with 18,000 inhabitants, but proved unhealthy, and has not now 1500.

Mauchline, a picturesque town of Scotland, in Ayrshire, on the river Ayr, 11 miles N.E. of Ayr by the Glasgow and South-Western Railway. The parish church, rebuilt in 1829, is a red sandstone structure with a turreted tower. There is a monument on the Green to the memory of five covenanters who suffered death in 1685. M. Hill, part of the long ridge of Kyle, a little to the N.E. of the town, commands a fine prospect of the surrounding country. M. is noted for the manufacture of snuff-boxes, cigar-cases, and various fancy articles. Pop. (1871) 1574. The genius of Robert Burns has dowered the town and neighbourhood with immortal interest. Mossiel, a small farm about a mile from M., was for some years the residence of the poet. M. Kirk was the scene of the 'Holy Fair,' and the change-house of 'Poesie Nancie' the 'howf' of the 'Jolly Beggars.'

Mau'i, the third largest of the Sandwich Islands, lies to the N.E. of Hawaii, is nearly separated into two parts, and has an area of 750 sq. miles. It is very mountainous, reaching a height of 10,200 feet in Manna Haleakala. The only port is Lahaina, on the E. coast.

Maunbhum, a district of Bengal, British India, occupying the hilly border land between Chota Nagpore and the Gangetic delta. Area, 4914 sq. miles; pop. (1872) 995,570. The staple crop is rice. Iron is wrought in the hills, and a coalfield is known to exist. The most valuable product is soapstone, which is carved into cups, plates, and idols, and largely exported. The chief town is Puruliah. This tract, owing to its remoteness, suffered severely during the famine of 1866.

Maund (*man*), the standard weight throughout India, used for measuring heavy commodities. It is universally composed of 40 *seers*, but unfortunately the *seer* is itself a variable weight. The standard M. is equivalent to about 82 lbs.; but for ordinary purposes of conversion it may be taken as = 80 lbs., or 28 to the ton. In various parts of India, however, the local M. varies from 90 to 28 lbs.

Maundy Thursday is the Thursday before Easter. Two customs have been associated with the day from very early times. First, it was customary for pious persons, especially the wealthy and the great, even kings and queens, to wash the feet of a number of poor people, in obedience to the injunction of Christ after washing the disciples' feet: a custom which is kept up by the Pope to this day. In this connection the name is supposed to be a corruption of Latin *mandatum*, 'command,' in John xiii. 34. Another custom was to give certain poor people—those whose feet were washed, or without the foot-washing—doles of bread, clothes, or money; a custom which is yet kept up by the sovereign of Great Britain. Hence the name has been derived also from Old Eng. *maund*, 'a large basket,' and from Fr. *maundier*, 'to beg.' See Brand's *Popular Antiquities*.

Maupe'tuis, **Pierre Louis Moreau de**, was born at St. Malo, July 17, 1698, educated at the Collège de la Marche, Paris, served for some years in the army, forsook it to pursue a

scientific career, and read a *mémoire* before the Academy of Science (1724) entitled *La Forme des Instruments de Musique*. In 1728 M. visited England, was received into the Royal Society, and on his return to Paris became the chief disseminator of the Newtonian theory of physics. *Figure de la Terre déterminée par les Observations*, published in 1738, was a book containing the experiences of M. in Lapland, to which he was sent to get the measurement of a degree of longitude, in order to settle the question as to the perfect rotundity of the earth. In 1740, Friedrich II., who wished to create an Academy of Science, invited M. to Berlin, where, after having been captured at the battle of Mollwitz and sent back to France, he was ultimately successful in organising an institution over which he was placed as President. But 'this big, glaring, geometrical bully in red wig,' as Mr. Carlyle calls him, who, as 'flattener of the earth, is, with his own flattish red countenance and impenetrable stony eyes, a man formidable to look upon,' was too overbearing for his post. In 1750 he quarrelled with König, a Dutch professor, because the latter combated his *Cosmologie*. Shortly afterwards he quarrelled with Voltaire, who has handed him down to the laughter of posterity in his *Micromégas* and *Diatribes du Docteur Akakia*. M. died at Basel, July 27, 1759. His *Œuvres* were published at Paris in 4 vols., 1752. See Damieon's *Mémoires sur M.* (Par., 1858), and Carlyle's *Frederick the Great*, vols. iii., iv., v., vi., and viii.

Maurice. See MORITZ.

Maurice, Rev. Frederick Denison, D.D., son of a Unitarian minister, was born 29th August 1806, educated at Cambridge, where he made the friendship at the 'Union' of Trench, Buller, Sterling, Milnes, and others, forsook the University (1826), and began to write for the *Athenæum*, recently founded. 'It was,' says Mr. Carlyle, 'about the end of 1828 that readers of periodical literature, and *quidnuncs* in those departments, began to report the appearance, in a paper called the *Athenæum*, of writings showing a superior brilliancy and height of aim.' For two years M. worked away at literature, and published *Eustace Conyers*, a novel; but under the influence of Coleridge his views began to change. Believing at last that the English Church, by being spiritualised and made intellectually reasonable, 'became once more a living ship of the desert, and invariably bore you over stock and stone,' M. went to Oxford, graduated M.A. (1831), and was ordained an Episcopal clergyman. Throughout his career he gained distinction by leading several different movements. His revolt from the Augustinian theology, and his insistence upon more spiritual conceptions of God and destiny, though it obtained for him a large following of the 'Broad Church' party, brought about his ears the fierce reprobation of the orthodox. Ultimately M. was compelled to resign the Professorship of Divinity in King's College, London. Among his best theological productions are *The Doctrine of Sacrifice*, *Theological Essays*, and *The Kingdom of Christ*. M. devoted himself also to strictly philosophical work, which took shape in his *Mental and Moral Philosophy*, and in articles contributed to the *Encyclopædia Britannica*. In 1866 he was appointed Professor of Moral Philosophy at Cambridge. He died 1st April 1872. M. had most definite social aims before him, attempting in the Christian socialist movement to abolish competitive labour, and to establish a kind of enlightened and peaceful communism among the working-classes. His success as founder and president of the Working Men's College was great and widely recognised. As a writer, M. is delicate, subtle, and refined. No more pellucid English than his has been written in the 19th c. His opponents complained of his nebulous thinking, but it may be doubted if their difficulty in apprehending him was not the sign of a radical weakness in themselves. Seldom, indeed, has purer, tenderer, or truer religious thought found expression than in the writings of this saintly heretic.

Mauricius, Flavius Tiberius, was born of an ancient Roman family at Arabissus, in Cappadocia (circa 539 A.D.), and spent his youth at the court of Justin II. Appointed *magister equitum*, he served with distinction against Khosru I. (q. v.), winning the honours of a triumph, and on August 13, 582, succeeded Tiberius on the Byzantine throne. The chief events of his reign were a great victory over the Persians at Solacoon (586), and the restoration by M. of Khosru II. to the throne of Persia (591); a war with the Avars (587), and their capture of 12,000

Roman veterans (600); the revolt of Phocas (q. v.), and the flight and assassination of M. and his six sons (November 27, 602). Though greater as a general than as a ruler, M. was one of the best Eastern emperors—bold, firm, and liberal to his subjects. He wrote twelve books on military tactics, *Strategika*, published, with a Latin version, by John Scheffer (Upsala, 1664).

Mauritania, or **Mauretania**, was in ancient times the N.W. part of Africa, so called from the Mauri or Marusii. After the last of the dynasty of Bocchus died in 32 B.C., Augustus gave the country to Juba as compensation for Numidia, which had become a Roman province. In 43 A.D. Claudius made M. also a Roman province, dividing it at the river Molochath into M. Tingitana, with the capital Tingis (now Tangier), and M. Cæsariensis, with the capital Cæsarea (Shershel). In the 7th c. M. was seized by the Arabs.

Mauritia. The most universally distributed palm throughout the basins of the Amazon and Orinoco is *M. flexuosa*, and there are few palms about which more has been written. It abounds mostly on the shores of low flat islands and about swampy lakes, and to the native is

'At once his dome, his robe, his fruit, his arms.'

—*Seasons*, l. 837.

The genus M. is peculiar to S. America, and the various species rise to the height of 100 to 150 feet, bearing a crown of enormous fan-shaped leaves, amongst which the pendulous flower spikes are produced.

Mauritius, or **Isle of France**, an island in the Indian Ocean belonging to Great Britain, and lying between 19° 58'–20° 33' S. lat., and 57° 17'–57° 46' E. long. It is nearly elliptical in shape, and has an area of 676 sq. miles. M. was discovered in 1505 by the Portuguese, but they made no practical use of their discovery. In 1598 the Dutch established a settlement on the island, to which they gave the name of Maurice, in honour of their Prince. They abandoned it, however, in 1710, and in 1721 it was taken possession of by the French, who kept it till 1810, when it was captured by Britain, to whom the seizure was confirmed at the peace of 1814. M. is of volcanic formation, and though volcanic action in it has long since ceased, eruptions and earthquakes occurring in Reunion (q. v.), 120 miles off, are felt in M. The latter is mountainous, and some of the isolated peaks are curiously shaped. The most remarkable, Pieter Botte, consists of a spire 2840 feet high, crowned by a dome of rock larger than the point on which it rests. The centre of the island is occupied by a plateau 1200 feet above the sea level. The rivers are torrents in winter, but mere brooks in summer. The coasts are fringed by dangerous coral reefs, and there are only two harbours adapted to shipping, viz., that of Port Louis (q. v.), the capital, on the N.W., and that of Mahébourg, or Grand Port, on the S.E. On the coast the climate is hot and unhealthy, but on the hills and central plateau it is much more bearable. Smallpox and cholera have at different times committed great ravages in the island. The mean annual rainfall at Port Louis is 39½ inches, most of which falls from October to April, though there are four seasons. Terrible hurricanes at times sweep the island from December to March, doing fearful havoc. One of these storms, in March 1874, lasted for five days. The fury of the hurricanes, however, is said to have decreased of late years, a result attributed to the lessening of the humidity of the climate by the clearing away of the forests which formerly covered the whole island. The soil of M. is fertile, though stony in some districts. Traces of iron are abundant, and at one time the metal was extensively worked. By far the most important crop cultivated is sugar, of which very large quantities are exported. The plantations are wrought by Coolies (q. v.) imported from India. M. possesses two lines of railway, connecting Port Louis with the northern and eastern districts, and of an aggregate length of 65 miles. The total value of the imports of M. during 1876 was £2,284,213, and of the exports, £3,273,822. The island is divided into ten districts, and is ruled by a governor appointed by the crown, an executive council of five members, and a legislative council consisting of seven official and eleven non-official members. The revenue in 1875 was £692,894, and the expenditure £775,836. The islands of Rodriguez (q. v.), the Seychelles (q. v.), and one or two of less importance, are dependencies of M. The population of M. is of the most heterogeneous character, being made up of French and English colonists, Creoles (the descendants of Europeans

and former slaves imported from Africa and Madagascar), coolies from different parts of India, and Chinese. The total population of the island at the close of 1875 was 344,602, giving the very high average of 509 to the square mile. The Indian population numbered 236,535, of whom fully two-thirds were males.

Maurokorda'tos, Alexander, born February 15, 1791, at Constantinople, played a leading part throughout the Greek War of Independence (1821-29) as head of the 'citizen primates,' in opposition to the Palikari chieftains under Kolokotronis, and rendered good service at Peta, Missolonghi, Navarino, and Sphacteria. During the reign of Otho I. he stood at the head of five ministries, in 1833, 1840, 1844, 1850, and 1854, and served as ambassador to the courts of Munich, Berlin, London, Constantinople, and Paris. He died at Ægina, August 18, 1865. A brilliant scholar, fluently speaking seven languages, and an enlightened patriot, M. was ever the upholder of an English in contradistinction to a Russian policy.

Mau'ry, Matthew Fontaine, LL.D., a celebrated writer on navigation and kindred subjects, was born in Virginia, U.S., January 14, 1806. He entered the navy and became lieutenant in 1836, but was forced to retire from active service in 1839, when he met with an accident which lamed him. He was then appointed to the Hydrographical Office at Washington, and was made Superintendent of the National Observatory in 1844. In the civil war he sided with the Confederates. In 1868 he became Professor of Physics in the Virginia Military Institute, and died at Lexington, February 1, 1873. His greatest work is *The Physical Geography of the Sea* (1855), in which are discussed for the first time with any fulness or attempt at explanation the phenomena connected with ocean currents. His *Treatise on Navigation* (1835) is still a text-book in the United States Navy; while the *Wind and Current Charts* issued by the National Observatory are based upon his valuable researches.

Mausole'um, a stately sepulchral monument, was originally the name of the tomb erected by the Carian queen Artemisia at Halicarnassus, to commemorate her husband Mausolus, which was so splendid as to be counted one of the seven wonders of the world. It was described by Pliny, after whom it was extant for several centuries, though it was at last destroyed by an earthquake. In 1404 the Knights of St. John built a castle there from its ruins, and from these Lord Stratford de Redcliffe, with permission of the Turkish government, removed some bas-reliefs to the British Museum in 1838. In 1856 Consul Newton brought to light the whole foundation of the M., with numerous sculptures, colossal statues, &c.

Mauve. See ANILINE COLOURS.

Maw-Seed (Ger. *magsamen*, Polish *mak*, 'poppy seed'), the seeds of *Papaver somniferum*, sold as a food for cage-birds, but in Poland and elsewhere used for human food. They have an agreeable nut-like flavour.

Maxill'a, in Anatomy, the name given to the upper jaw, which consists of the M. proper, and of a part known as the *premaxilla*. In the latter are situated the upper incisor teeth; the upper canines being placed in the M. just behind the suture which marks the separation of the premaxilla from the M. The name M. is also applied to indicate the lesser jaws of *Arthropoda*—e.g., insects, crustaceans, &c.

Maxill'ary Arteries (*maxilla*, 'the jaw'). The internal maxillary artery, the larger of the two terminal branches of the external carotid, is imbedded in the parotid gland, and begins on a level with the lower lobe of the ear. It sends off fifteen branches, and supplies the deep structures of the face.

Maximilian I., Germano-Roman Emperor, son of Friedrich III., was born at Neustadt, near Vienna, 21st March 1459, married Mary of Burgundy (1478), adding thereby to the House of Austria the Low Countries and Burgundy, and became King of the Romans (1486). Before becoming emperor (1493) he had to conduct campaigns against the French, Hungarians, and Turks. In 1494 M. created his son Philip governor of the Low Countries, who afterwards married Joanna, from whom sprang Charles and Ferdinand, both of whom became emperors. He summoned a diet at Worms (1495), at which a permanent 'public peace' was proclaimed, and the right of private feuds discontinued, a court of appeal being established to see the system worked. But he was constantly inveigled in wars, with which

Germany ought to have had little to do, through the ambitious eye he had upon Italy. Owing to his poverty he was unable to fight Louis XII. or Ferdinand on equal terms, and at one time he served under Henry VIII. for 100 crowns a day. His Bavarian war was the most successful. In 1508 M. took the title of 'Emperor Elect,' which was sanctioned by Pope Julius II., and to it he afterwards added the title 'King of or in Germany.' Among other important reforms M. divided Germany into 'circles,' each circle having its own states over which 'directors' presided. He died at Wels in Upper Austria, 12th January 1519. M. was an ambitious monarch, strong and restless, and ever scheming for his own aggrandisement. But his love of glory was ennobled by a no less ardent love of letters. He drew to his court numerous scholars and authors, and wrote himself, both in prose and verse. His correspondence with his daughter Margaret was published by M. le Glay (Par. 1839). See Klüpfel, *Kaiser M. I.* (Berl. 1864).

Maximilian II., Joseph, son of Ludwig I., King of Bavaria, was born 28th November 1811, educated at the university of Göttingen, became major-general (1831), entered the State Council (1836), and married Princess Marie Hedwige (1842). He was called to the Bavarian throne in 1848, and started his career by promising an amnesty in favour of the Revolutionists, and by proposing measures in behalf of popular representation. In 1853 he travelled in Italy, and kept free of the Crimean war; in 1859 he was anxious to join the Austrians in their war against Italy, but the Peace of Solferino put an end to his 'federal obligations.' Around him he kept men devoted to science, art, and literature. He is even credited with 'a composition refuting' the philosophical system of Hegel. M. died at Munich, 10th March 1864. See Söhl's *Biography of M.* (1867).

Maximilian, Ferdinand Joseph, Emperor of Mexico, son of the Archduke Franz Karl of Austria, was born July 6, 1832. Entering the Austrian navy, he became commander-in-chief of the Imperial Marine in 1859. At the instigation of the Emperor Napoleon, the throne of Mexico was offered to him in 1864. He accepted it on the 10th of April, and assumed the government on 12th June. His short reign was beset with difficulties. On the withdrawal of the French troops, in February 1867, he was besieged by the Republicans at Querétaro, taken prisoner May 15, 1867, and shot, June 19, 1867. His remains were interred at Vienna, January 18, 1868. M. was more of a litterateur than a statesman. Seven volumes of his writings on travel, politics, and miscellaneous subjects have been published at Leipzig and Vienna (1865-67) under the title of *Aus meinem Leben, Reiseskizzen, Aphorismen*, &c. See *L'Empereur M.*, by Eugene de Keratry (Par. 1867); *M. I.*, by Hellwald (Vien. 1868); and *Mexico under M.*, by Kendall (Lond. 1872). His Empress Charlotte survives him, but since her husband's misfortunes has remained hopelessly insane.

Maximum and Minimum. When the rate of variation of a function of one or more independent and continuously varying variables changes sign, i.e., if the function begin to decrease in value after having up till that time increased, or to increase after having up till then decreased—the function is then said to have reached a maximum or minimum value as the case may be. Take, for example, the function, $y = ax - bx^2$. The rate of variation of y with respect to x is $\frac{dy}{dx} = a - 2bx$, a quantity which is evidently positive as long as $2bx$ is less than a , and negative for all values of x which make $2bx$ greater than a . For the value $x = \frac{a}{2b}$, $\frac{dy}{dx} = 0$, hence, for this value, $\frac{dy}{dx}$ changes sign, and therefore y is a maximum or minimum when $x = \frac{a}{2b}$. To determine which it is, it is necessary to take the second differential coefficient and find what its sign is for this value of x . In this case $\frac{d^2y}{dx^2} = -2b$, a negative quantity; and hence the value is a maximum.

Max'well, James Clerk, LL.D., F.R.S., &c., a distinguished living physicist, was born at Edinburgh in 1831. After studying at the University there, he went to Cambridge, where he came out senior wrangler in 1854. In 1856 he became Professor of Natural Philosophy at Marischal College, Aberdeen, and in 1860 at King's College, London. Since 1871 he has been

Professor of Experimental Physics at Cambridge. His writings in various departments of science are of great merit and originality. He has done more than any other mathematician, with the exception, perhaps, of Clausius, to establish the kinetic theory of gases; and his mathematical theory of electricity, based entirely upon Faraday's valuable researches, is now generally accepted by the scientific world. His chief works are—*Theory of Heat* (1871); *Electricity and Magnetism* (2 vols. 1873); and *Matter and Motion* (1877).

Maxwell, Sir William Stirling, was born at Kenmure in 1818, educated at Trinity College, Cambridge, and graduated M.A. in 1843. In 1848 appeared his *Annals of the Artists of Spain*, the fruit of a strong artistic enthusiasm properly directed by a study of the different schools in France and Spain. *Cloister Life of Charles V.* appeared in 1852, *Velasquez and his Works* in 1855. Returned in 1852 to the House of Commons, he sat until 1865 in the Conservative interest for the county of Perthshire. In 1866 he succeeded his maternal uncle, Sir John Maxwell, in the baronetcy. He was appointed Lord Rector of St. Andrew's University (1863), of the Edinburgh University (1872), Chancellor of the University of Glasgow (1875), and Chairman of the Scotch Education Board. M. was returned to Parliament a second time for Perthshire (1872). In the spring of 1877 he married the Hon. Mrs. Norton, who died in June of the same year. He himself died at Venice, 15th January 1878. M. had a graceful and incisive style; his sentiment was slightly iced with irony, but his intellect was acute and strong.

May (Lat. *Maius*; cf. Sansk. *mah*, 'grow,' Lat. *mag-nus* and *major*), the third month of the early Roman, and fifth of the Julian year. The Romans derived its name from *Maius* and *Maia*, two deities of ancient Latium, probably equivalent to Jovis and Tellus. The mysterious rites of the Bona Dea were performed on the first of this month, which has been with the English from time immemorial the popular festival of May-day.

May, Thomas, a poet and historian, was born at Mayfield, Sussex, in 1594, and proceeded from Sidney College, Cambridge, to Gray's Inn; but embracing the profession of letters, he became a favourite of Charles I., and during his residence at court produced five plays, two poems on the reigns of Henry II. (1633) and Edward III. (1635), and translations of Virgil's *Georgics* (1622) and Lucan's *Pharsalia* (1627), the latter with a supplement in seven books, which he afterwards rendered into Latin (1640). On the outbreak of the civil war, M. sided with the Commons, and, appointed secretary and historiographer to the Parliament, wrote a *History of the Parliament of England which began Nov. 3, 1640* (Lat. vers. 1647; Eng. 1650; Fr. trans. 1823), and a *Breviary of the History of the Parliament* (1650). He died, choked by his nightcap strings, November 13, 1650.

Mayaguez, a town of Porto Rico, 66 miles S.W. of San Juan, is situated 1 mile inland, being connected with its port by a tramway. There is safe anchorage, and the town, well supplied with gas and water, is the most advanced place in the island. In 1875 the total value of exports was £601,003, of which £361,709 were coffee, and £229,550 sugar and molasses. Estimated pop. (1875) 20,000.

Maybole, a town of Scotland, in Ayrshire, 9 miles S.W. of Ayr by rail. It is hemmed in from sight of the sea by a range of low hills, and its chief object of interest is the old castle, an ancient residence of the Earls of Cassillis. Here John Knox disputed with Quentin Kennedy, head of the neighbouring Abbey of Crossraguel, the remains of which are very striking, and attract great numbers of visitors. The chief industries of M. are the manufacture of shoes and of agricultural implements. There were (September 1877) five large shoe factories, which turned out annually about 400,000 pairs of shoes, representing a value of nearly £90,000. Pop. (1871) 3797.

Mayenne, the French name of *Maine* (q. v.).

Mayenne, a department of France, part of Old Anjou and Maine, is bounded N. by Manchè and Orne, S. by Maine-et-Loire, W. by Ille-et-Villaine, and E. by Sarthe. Area, 1996 sq. miles; pop. (1872) 350,637. It is traversed from N. to S. by the river M. (Lat. *Meduana*), an affluent of the Loire, and bounded in the W. by the Collines-du-Maine, reaching a height of 329 metres. The soil is fertile but poorly cultivated, and

the chief crops are barley, oats, and buckwheat, amounting in annual value to 35,000,000 francs. Cider is produced to the extent yearly of 240,000 hectolitres. M. also yields much iron, coal, marble, and slate, and the principal manufactures are linens, cottons, hemp, paper, leather, and iron wares. Laval is the capital. M. is crossed from E. to W. by the Paris & Brest Railway.

Mayenne, a town of France, in the department of the same name, on the right bank of the M., 20 miles N.E. of Laval by rail. It manufactures calicoes, linens, leather, oil, &c., and is an important market for cattle. On a rocky height over the river stands an old castle of the Dukes of Mayenne. Pop. (1872) 8227.

Mayfly. See EPHEMERA.

Maynooth College, an Irish Roman Catholic seminary at Maynooth (Ir. Gael. *Magh-Nuadhat*, i.e., 'The Plain of Nuat, a king of Leinster') or Laraghbryan, a village in the county of Kildare, 13 miles N.W. of Dublin by rail. It was founded (1795) by an Act of the Irish Parliament to supply the void created by the suppression, at the time of the Revolution, of the Irish colleges in France, and its original endowment, consisting of a yearly grant of £8928, was increased in June 1845 to £26,000 annually, with a special grant of £30,000 for the enlargement of the buildings. By the Irish Church Act (July 26, 1869), the Maynooth Grant ceased after January 1, 1871, being with the *Regium Donum* commuted for £1,100,000. The buildings consist of an old and a new quadrangle, the latter of which, designed by Pugin, contains the refectory, a library of 12,000 volumes, lecture-rooms, &c. The governing body is composed of eleven clerical and seven lay members; and the foundation of a president, vice-president, four deans, a bursar, twelve professors, and a librarian. In 1871 the number of students was 475.

Mayo (Ir. Gael. *Magh-Eò*, 'The Plain of the Yews,' to which St. Colman retired, and from which the county took its name), a maritime county of Ireland, in the province of Connaught, is bounded E. by Sligo and Roscommon, S. by Galway, and W. and N. by the Atlantic Ocean. Area, 2137 sq. miles; pop. (1871) 246,030. The coast-line is deeply indented by Clew Bay (q. v.), Blacksod Bay, Broad Haven, and Killala Bay, and is fringed by Clare, Achil (q. v.), and other islands; while the Mallet promontory, 15 miles in length, is only connected with the mainland by a narrow isthmus 5 miles long. The western half of M. contains thirteen summits exceeding 2000 feet of altitude, Mulrea, the highest, rising 2683 feet; the eastern is more level, with numerous bogs and lakes—Lough Conn (q. v.) and portions of Loughs Mask and Corrib (q. v.). In 1876, 181,679 acres were under crop, 522,781 in pasture, 10,119 of plantation, and 603,202 waste, bog, water, &c. There were 17,411 horses, 19,259 asses, 173,596 cattle, 277,225 sheep, and 57,215 pigs. Agriculture, fishing, brewing, and distilling, are the chief industries, the linen manufacture having greatly declined. Marble, slate, potter's clay, and manganese are found in abundance. M. returns two members to Parliament, is traversed by the Great Northern and Western Railway, and the chief towns are Castlebar (the capital), Ballina, and Westport. Among the antiquities of the county are five round towers, and the ruins of six abbeys and ten castles.

Mayo, Richard Southwell Bourke, Sixth Earl of, was born at Dublin in 1822. He was brought up at home, and first entered Parliament in 1847 as member for County Kildare, but afterwards represented Cockermouth. He was three times Chief Secretary of Ireland under a Conservative ministry; in one of these terms of office he had to deal with the Fenian conspiracy, and was the member of the Cabinet most directly concerned in opposing Mr. Gladstone's Resolutions against the Irish Church. In 1868 he received the post of Indian Viceroy. By his capacity for work and strong personal character, he endeared himself both to the European and native world. He adopted a firm, but not meddlesome, foreign policy; reformed the finances, and changed the chronic deficit for a surplus; while he favoured many well-advised schemes of internal improvement. No great historical event marks his government, but all India mourned when he was struck down by the hand of a Mohammedan assassin, 8th February 1872, while he was visiting the penal settlement of Port Blair, in the Andaman Islands. There was no political or religious

animus in the crime. His body was brought home to be buried in Ireland with a public funeral, and a pension was settled upon his widow. In his young days he published a book on his travels in Russia, *St. Petersburg and Moscow* (Lond. 1846). His son, the present Earl of M., an officer in the Grenadier Guards, has written *Sport in Abyssinia* (1876). See *A Life of the Earl of M.*, by W. W. Hunter (2d ed. Lond. 1876).

Mayor (Lat. *major*), the title in England and Ireland of the chief magistrate of a Corporation (q. v.). It answers to the Old Eng. *portreeve* and the Scotch *Provost* (q. v.), and was introduced by the Normans in the reign of Henry I. from France, where the mayors of the palace had risen to almost absolute power under the faintest Merwings, and where a *maire* is still at the head of each commune. The first M. of London was Henry Fitz-Alwyn (1189), and to his successor in 1354 Edward III. granted the prefix *Lord*, which was also bestowed on the M. of Dublin by Charles II. in 1665. The election of mayors takes place on November 9th; their office is tenable for a year, but they may be re-elected. The Lord Mayor of London receives £8000 per annum, with the use of the Mansion House, carriages, &c.; but the glories of his office have been greatly curtailed since the days of Pickard and Whittington. The French, however, still retain all their old belief in his despotic powers, as was shown on the occasion of the visit of the Right Hon. David Stone to Paris, for the opening of the Grand Opera (January 5, 1875).

Mayor's Court of London, Procedure Act. Under this Act (1857), if either party to any cause in which the value in dispute exceeds £20, is dissatisfied with the decision of the court in point of law, or upon the admission or rejection of evidence, he may appeal to one of the superior courts. Notice of intention to appeal must be given to the opposite party, or to his attorney, within two days of the date of judgment, and security for the costs of the appeal must be given and approved of by the registrar of the court.

Mayotta, one of the Comoro Islands (q. v.), in the Mozambique Channel. It is 21 miles long and 7 broad, and is encircled by dangerous reefs which extend several miles from the land. M. is mountainous, and traces of volcanic action are everywhere abundant. The soil is fertile, and a considerable quantity of sugar is exported. In 1843 the French took possession of M., and on the small outlying islet of Zaudzi they have erected a fort, which is garrisoned by 100 men. The chief value of M. to France is as a harbour of refuge for her ships. Pop. 12,000, most of whom are Arabs or Sakalavas from Madagascar, who fled thence from the Hovas. See **MADAGASCAR**.

Mazamet, a town in the S. of France, department of Tarn, at the foot of the Montagnes Noires, and on the Annette, 33 miles S.S.E. of Albi by rail. It has considerable manufactures of woollens, which, with linens and hydraulic limestone, it produces annually to the value of £720,000. Pop. (1872) 10,500.

Mazanderan, a province in the N. of Persia, is bounded N. by the Caspian, S. by Irak-Ajemi, from which it is parted by the Elbruz Mountains, E. by Astrabad, and W. by Ghilan. It is 200 miles long from E. to W., with an average breadth of 60 miles. Marshy, jungly plains, in some places 30 miles broad, skirt the Caspian, and in the S. the Elbruz sends out bold, densely wooded spurs, traversed in all directions by wild, romantic glens, and behind which tower the peaks and masses of the main range in rocky, naked grandeur, snow-spotted even in September. M. is watered by some fifty small streams, all well stocked with fish. Among the animals are the tiger, panther, bear, wolf, deer, and wild boar, while pheasants, woodcocks, and wild ducks abound all over the province. The climate, though not so damp as Ghilan, is one of capricious extremes. The products are rice, sugar, cotton, mulberry, and a vast variety of excellent fruits. Firdusi calls M. the 'land of roses.' On the coast the fisheries of sturgeon, carp, and salmon furnish the chief supply of caviare to the Russian market. The trade is principally with Russia through the port of Baku. The capital is Sari. The inhabitants, the most warlike of the Persians, furnish to the state about 12,000 foot soldiers. Besides Persian, a Turkish dialect is spoken by the peasantry.

Mazarin, Jules, or Giulio Mazari'ni, a great French politician, was born either at Rome or at Piscina, 14th July 1602. His family was probably Sicilian. Educated at Rome and Alcalá, he at first had a small command in the army of Pope Urban

VIII., and afterwards distinguished himself in the diplomatic negotiations which followed the Mantua Succession War (1628-30). Through the favour of the Barberini family, the recommendations of Richelieu, and the high connections by marriage which his family made at Rome, he was appointed Nuncio Extraordinary at the Court of France, with instructions to demand restitution of the Duke of Lorraine's rights. Suspected of not serving Spanish interests properly, he was recalled. In 1640 he obtained the cardinal's hat, although he was never ordained a priest, and openly entered the diplomatic service of Richelieu, who in his dying letter bequeathed to him the task of securing the glory of France by a general peace (1642). M.'s first acts were merciful: the restoration to favour of D'Orleans, Bassompierre, Vitry, Vendôme, and the liberation of many state prisoners. On the death of Louis XIII. (1643), his graceful and insinuating manners rendered the regency of Anne of Austria purely nominal, and for eighteen years, with a short interval, he reigned supreme in France. The popularity of the victories of D'Enghien and Turenne enabled him easily to suppress the conspiracy of the *Importants*, of whom Beaufort was the chief, and to disregard the enmity of Innocent X. Anxious to add Elsass and the Low Countries to France, he proposed the marriage of Louis XIV. to Maria Theresa, the Infanta of Spain. Elsass was practically gained by the Treaties of Westphalia and Munster (1648), both to a large extent the work of M. In the meantime he had been living in a magnificent style. He had built the Palais M., and had introduced the Italian opera to France. M., however, had not the administrative abilities of Richelieu. The great cost of Government was aggravated by the permitted corruption and oppression of the collectors. The local Parliaments revived the question of 'la paulette,' and the first war of the Fronde (q. v.) began. In the period from 1649-52 more than 4000 satirical writings against M. issued from the French press. For two years he was kept in disgrace and exile by the Parliamentary party, whom he used to call the Cromwells and Fairfaxes. Not his least injury was the sale in fragments of his splendid library. The Pacification of Bordeaux (August 1653) saw him back again at the head of affairs. He pushed on successfully the war against Spain, concluded with Lockhart, Cromwell's nephew, a treaty of commerce and of alliance with England; on the election of Leopold I. arranged the League of the Rhine, so advantageous to France; and finally, by the Peace of the Pyrenees (1659), he secured the Infanta and completed the humiliation of both branches of the House of Austria. From this time until his death at Vincennes, 9th March 1661, M. was supreme in appearance as well as in reality. He abandoned his romantic relations with the Queen-mother, but he pushed his nieces Martinozzi and Mancini into brilliant marriages. M. was not a great statesman or patriot. He neglected the permanent interests of France. But he was strongly attached to the country of his adoption, whose welfare, indeed, he had identified with his own success in the crafty game of foreign politics which occupied his life. In home politics he worked by bribery and the grossest flattery, and he systematically enriched himself at the expense of the nation. More humane and more selfish than Richelieu, he had none of that statesman's profound views of the future. There are three collections of M.'s letters (1693, 1710, and 1836); a life by Aubéry (1751); an endless number of contemporary memoirs, and many studies in the history of the period, such as V. Cousin's *La Jeunesse de M.*, &c. In 1872 M. Chéruel commenced the publication of the whole of M.'s *Correspondence*.

Mazatlan, a port of Mexico, state of Sinaloa, at the entrance of a river of the same name into the Gulf of California. Its harbour is exposed to S.W. winds, its drinking water poor, and its climate hot (during August reaching to 105° in the shade), but not unhealthy. M. is important for its exports of mining produce, especially of silver. In 1873 the value of exports was \$2,797,385, of which \$2,435,450 was in gold and silver bullion; that of the imports \$1,276,000. There entered and cleared the port 53 steamers and 26 sailing vessels of 117,493 tons. Pop. (1870) 12,706.

Mazeppa, Jan (Russian *Ivan Stepanovitch M.*) Hetman (q. v.) of the Cossacks, was born in 1645 (another account gives 1622) of a good family in Podolia or Little Russia. He was for a time page to Jan Kazimierz, king of Poland, but a Polish noble named Falibowski having caught him in an in-

trigue with his wife, bound him, lying naked on his back, to his own horse, which was then driven wild. The horse bore him to his home. In 1663 he left this for the Ukraine, where his feats of strength and daring pleased the people, and his superior intelligence soon made him the secretary and adjutant of the Hetman Samoilovitch, whom in 1687 he supplanted and succeeded. Peter the Great made him Prince of the Ukraine. M. plotted with Karl XII. of Sweden to bring the Ukraine under Poland, and openly joined him for that end in 1708. After the battle of Pultava (1709) he shared the ill-fortune of Karl, whom he accompanied to Bender, where he died in 1710. M. is the subject of two pictures by Horace Vernet, and the hero of one of Byron's poems, a romance by Bulgarin, and a drama by Gottschall.

Mazurka, a Polish dance in triple time, popular now in Germany and England. It has also been worked out into an independent instrumental form, notably by Chopin.

Mazza'ra, a seaport on the W. coast of Sicily, province of Trapani, at the mouth of the Mazarus, 10 miles S.S.E. of Marsala by rail. It is surrounded by quadrangular walls, 36 feet high, and has a ruined castle, of date 1072, and a cathedral of the 11th c., containing three fine old sarcophagi. M. is the residence of a bishop, who has a revenue of 200,000 francs. Some 600 vessels, mostly small, enter the port yearly. Pop. (1874) 12,155. Originally a colony of the Selinuntians, it was destroyed by Hannibal Gisco, B.C. 409. In 807 A.D. the Arabs landed at Ras-el-Belât (*Punta di Granitola*) a little to the S.

Mazzarino, a town of Sicily, province of Caltanissetta, 10 miles S.W. of Piazza. It has several fine churches, the palace of the Branciforte, a theatre, &c. Near it is the romantically situated castle of Grassuliato. Pop. (1874) 11,951.

Mazzi'ni, **Giusepp'e**, the apostle and creator of Italian unity, was born 28th June 1805, at Genoa, where his father was a physician. When the Piedmontese insurrection of 1821 broke down, he was already thinking of his country's future. He first tried to form a literary nationalist party, distinct from the conservative classicists and the moderate romantic school. He then perceived the necessity for direct action, and joined the Carbonari, whom, however, he describes as Machiavellian, materialist, and relying on the French initiative. Having himself suffered imprisonment, he aspired to point out the true way of revolution. In 1831-32, he organised 'La Giovine Italia' ('Young Italy'), from Marseille; in 1834, the Savoy Expedition; in 1835, along with the Polish refugees, the 'Association of Young Europe.' After expulsion successively from Italy, France, and Switzerland, he came in 1837 to England, where he remained constantly 'conspiring' till 1848. In February 1849 he was elected a member of the Tuscan Provisional Government, and, on 29th March 1849, one of the Triumvirs of Rome. Compelled by the French occupation to return to England, he was nevertheless the soul of the risings in Milan and Piedmont of 1853 and 1857, and of the Sicilian Expedition of 1860. He died in lonely and unsuspected privacy at Pisa, 11th March 1871. The Italian Government, to whom his idealistic republicanism was a permanent embarrassment, found it possible when he passed away to express its sense of his noble service to the nation by honouring his remains with a public funeral.

The principles of M.'s life are well stated in the statutes of La Giovine Italia (vol. i. of his collected works, 1864-70, Lond.), and in his writings in the journal of that society; and his political mission is described in his famous letter to Carlo Alberto, the *quondam* Carbonaro, when he ascended the throne of Piedmont in 1831. M. proclaimed the sovereignty of the people, which he based not on the 18th c. conception of liberty or rights, but on that of positive religious duty. He also asserted the unity of the Italian people, and foretold their great destiny, not only in elevating themselves, but in contributing to the civilisation of Europe. Hence, every attempt at resurrection must aim, not at municipal or local, but at national independence. To educate the whole people in the knowledge of their future and in the necessity of their acting for themselves against Austria and the Bourbon Houses, and even against partial monarchy on moderate principles, was the object of M.'s literary existence. He even drew up rules for the conduct of guerilla warfare. Among his leading books may be mentioned the *Apostolato Popolare*, and his *Royalty and Repub-*

licanism in Italy. He also wrote on general subjects for the London press—e.g., his paper on Carlyle in the *Westminster Review*. M. was the object of passionate affection, not only to his Italian fellow-workers, but also to politicians of the advanced school all over Europe. Still more may be said with truth. Every lover of freedom, progress, and purity profoundly honoured one in whose character the tenderest humanity was combined with the most devoted patriotism; who adorned a great political creed with the blended virtues of the martyr and the saint. See a Memoir by E. A. V. (Lond. 1875).

Mead, or **Metheglin** (Ir. Gael. *Meadh*, Sansk. *Madhu*, 'honey'), a spirituous liquor prepared by the fermentation of honey. Among Celtic races in early times the liquor occupied a prominent place, and the term honey-moon is said to have originated from the ancient Teutonic custom of using the beverage freely for thirty days after marriage.

Meadow Grass, as the book-name of a genus, is restricted to *Poa* (Gr. 'fodder'), two species of which, namely, *P. pratensis* and *P. trivialis*—the smooth-stalked and the rough-stalked M. G.—are valuable constituents of meadow herbage; they may be distinguished by the first having a creeping root stock. Even after the separation from the genus of *Glyceria*, &c. (see MANNA GRASS), it numbers about 100 known species, chiefly spread through cold and temperate regions of the world, from the sea level to very great altitudes. One species named *P. annua* may be said to be cosmopolitan. As far as Britain is concerned, it is the commonest plant of the flora, being found in all waste places where a plant can grow, even in the busy streets of London, and rising to 3200 feet in the Highlands. The Alpine species of the genus are botanically very interesting. *P. Abyssinica*, the teff of Abyssinia, has a grain that is made into bread of an agreeable acidulous taste. Several species are valuable as forming a good pasturage in moist saline soils, such as coast marshes, and *P. maritima*, besides this quality, helps by its creeping roots to bind the loose soil.

Meadow Saffron. See COLCHICUM.

Meal (Ger. *mehl*, Goth. *malan*, 'to grind'), is the coarsely ground or large-grained flour of any of the cereal seeds, or of other farinaceous products employed as food. From the important position the substance holds in human dietary, the term M. has come to indicate the entire fare of civilised man, whose periodical diets are called *meals*.

Meal Worm, the larva or grub of a beetle, the *Tenebrio molitor*, which lives among corn, meal, flour, and like substances. It is also frequently found among ship-biscuits which have been packed in casks. The M. W. is about an inch long. The body is smooth and glossy, and of cylindrical shape. The body of the perfect beetle is long and ovate, the legs are slender, and the tibiae or shins are spurred. An allied species is *T. obscurus*, which is said to have been imported into England in American flour. Meal Worms are kept by bird-dealers, and sold as food for canaries and other caged birds.

Mealy Bug, the name given to the *Coccus adonidum*, a species of *Coccida* or *Hemipterous* insects, and a near ally of the Cochineal insect (q. v.) (*C. cacti*). It is found in hothouses, and feeds on pine apples and other fruits. Its colour is red, and the body is covered with a powder or dust, the presence of which has given origin to the name.

Mean, in Mathematics, is the name given to a number, which is intermediate in value to two given numbers, and which is obtained from these numbers according to a certain rule. If three numbers are in arithmetical progression, the centre one is the arithmetic M. of the other two; if they are in geometrical progression, the centre one is the geometric M.; and if they are in harmonical progression, the centre one is the harmonic M. M. when used alone, always signifies the arithmetic M.

Mearns. See KINCARDINESHIRE.

Measles (known also as Rubeola and Morbilli), is an eruptive fever of the exanthematous group of zymotic diseases, most probably depending upon the development, within the body, of a specific *contagium vivum*. The origin of M. is unknown, and the specific contagium has never been known to be spontaneously developed, but has always been communicated directly or indirectly from the diseased to the healthy subject. The most prominent symptoms of M. are lassitude and shivering, followed by heat of skin, rapid pulse, thirst, and general febrile symptoms, resembling those of catarrh, or severe cold in the head. There is usually an affection of the bronchial mucous membrane, manifested by slight sore throat, dry cough, and a sensation of tightness of the chest, and on the fourth day of the febrile symptoms the characteristic rash appears. The rash never appears until a week after infection; it is often deferred until a fortnight; but the usual interval is ten or twelve days. M. has been inoculated, and then the interval between inoculation and the appearance of the rash was seven days. The initial processes of the disease occupy six days, of which the last four constitute the well-known catarrhal stage; so that there are but three days of incubation, even if we include the initial fever which terminates the incubation stage. This period of incubation is prolonged for a day or two when the disease is taken by infection. The longest interval between exposure to infection and the appearance of the rash is eighteen days. On the third or fourth day of the primary fever the first crop of the eruption appears on the face, neck, and upper extremities, consisting of minute red papulæ, which coalesce into crescentic patches. On the following day the second crop covers the trunk; and, on the third day, another crop appears on the lower extremities. On the fourth day, the eruption begins to decline on the face; on the fifth, on the trunk; on the sixth, on the lower extremities, and then terminates by resolution and a furfuraceous desquamation of the cuticle generally. The febrile symptoms attain their maximum intensity about the fifth day; and, after continuing about twenty-four hours, rapidly decline, the normal temperature being reached on the second day from the beginning of the effervescence. In very severe cases the decrease in temperature may be prolonged. Two varieties of M. are described, viz., Morbilli *mitiores*, and Morbilli *gravior*, the main characteristic of the latter form being that the eruption becomes suddenly black, or of a dark purple with a mixture of yellow. M. may be distinguished as follows from Scarlet Fever or Scarlatina (q. v.). In M. the rash appears from ten to twelve days after exposure; in scarlatina, from two to ten. In M. it appears generally on the fourth day of the fever; in scarlatina, on the second. In M. the rash resembles flea-bites, is of a pinkish red or raspberry hue, coalescing in crescentic patches, and extending in successive crops; in scarlatina, the patches are large, universally diffused, and of a bright scarlet colour. In M. coryza is a prominent symptom, and the tonsils are but little affected; while in scarlatina, coryza is seldom present, and the tonsils are almost always greatly enlarged. In M. the fever subsides on the disappearance of the eruption, but in scarlatina it may continue for weeks, or until the sore throat has healed. In M. the tertiary symptoms are inflammation of the lungs or pleura, but in scarlatina they are more usually inflammation of the joints and serous membranes; affections of the kidneys and dropsy.

The average mortality of M. is 1 in 15, and the chief danger arises from bronchial and pulmonary inflammation. No antidote to the poison of M. is known, and the rule is to interfere as little as possible so long as the disease is pursuing its normal course, and to moderate and subdue dangerous symptoms. The patient should be carefully protected from cold for a week or two after desquamation has taken place, and the hot or vapour bath should be frequently used. Anointing the body with glycerine and carbolic acid, or peroxide of hydrogen, will serve the purpose of imprisoning and destroying the specific contagium of the disease; but complete disinfection under skilled supervision will be necessary before the disease germs can be eradicated.

Meas'ure, in Music. See TIME.

Meath (Ir. Gael, *Midhe*), a county of Ireland, province of Leinster, is bounded N. by Monaghan and Cavan, S. by Kildare and King's County, W. by Westmeath, and E. by

Dublin, Louth, and the Irish Sea. Area, 579,861 statute acres; pop. (1871) 95,558. It has a coast-line of only 8 miles, and is watered by the Boyne, and its affluent the Blackwater. Part of the E. margin of the great Irish limestone plain, it has a loamy soil of great fertility, yielding good crops of oats, barley, wheat, beans, and pease, potatoes, turnips, mangold-wurzel, &c. In 1876 there were 140,714 acres under crops, 395,439 in grass, 10,568 in plantation, and 31,184 in bog, waste, and water. M. has (1876) 15,205 horses, 170,349 cattle, 217,069 sheep, and 17,085 pigs. The towns are Trim (the county town, pop. 2058), Cavan, Kells, and the S. part of Drogheda. M. returns two members to Parliament. Anciently part of an Irish kingdom of the same name, it was overrun by the Danes in the 9th c., taken by Strongbow about 1171, and granted by Henry II. to Hugh de Lacy. The ancient royal seat was the famous Temor or 'Tara of the kings.' Among the antiquities in which M. is singularly rich, the chief are the great rath at Tara, and the round towers at Kells and Donaghmore. It has also the ruins of some twelve castles and seventeen ecclesiastical buildings.

Meaux, a town of France, department of Seine-et-Marne, on the river Marne and the Ourcq canal, 28 miles E.N.E. of Paris by rail. M. is a well-built town, with fine promenades, and has a Gothic cathedral, dating from the 12th c., and containing the grave of Bossuet (q. v.), who was bishop of M. It is the centre of an extensive trade with Paris in corn, *fromages de Brie* (3-4 million francs yearly), and other provisions. The chief industries are copper-founding, distilling, cotton-spinning, and the manufacture of flour, pickles, beer, and agricultural instruments. M. is the Roman *Jatunum*, chief town of the *Meldi*, and has been a bishop's see from 375. Pop. (1872) 9528.

Mecca, a town of Arabia, capital of the Turkish vilayet of Hedjaz, stands in a narrow, sandy valley watered by the Wadi-el-Tarafeyn, 249 miles S. of Medina, and 60 E. of the seaport of Jeddah (q. v.). With unpaved, sandy streets, M. is yet better built, and presents more of a European aspect, than most Eastern cities; its houses being of stone, three-storied, and with numerous windows looking on the streets. The only open space contains the chief mosque—the *Beitullah* ('house of God'), or *El-Haram* ('the inviolate')—inclosing the Kaaba (q. v.), and with nineteen gates and seven lofty minarets. There are no khans, no bazaars, only a few residences of the sherif and other magistrates, and a castle, on the eastern side of the valley, commanding the town, but itself commanded from the surrounding heights. The manufacture of rosaries is the sole industry of the inhabitants, who subsist by the entertainment of pilgrims, all Mohammedans being bound to visit M. at least once in their lives. In the *hajj* ('pilgrimage') of 1875, the number of pilgrims was reckoned at 140,000, of whom 40,000 came by sea, the remainder by caravans across the continent. To the falling off of pilgrims is due the decrease in the pop. of M.—from 100,000 to 45,000, according to Burton. The history of M. (the *Macoraba* of Ptolemy) begins with Mohammed (q. v.), who was born there (571), and whose successors the califs retained it in their power until the fall of Bagdad (1238). Later the sultans of Turkey assumed the title 'Protector of the holy cities M. and Medina,' and nominated the grand sherifs. It fell into the hands of the Wahabis (q. v.) in 1803, was held by the Egyptian pashas (1818-41), and reverted to Turkey, along with Hedjaz, in 1867. See Burton, *Pilgrimage to El Medinah and Meccah* (Lond. 1856); and H. von Maltzan, *Meine Wallfahrt nach Mekka* (Leips. 1863).

Mechanics is strictly that branch of applied mathematics which treats of the action of machines. In this sense it was understood by Newton, but since his time the term has been very generally applied so as to embrace the whole range of mathematical physics or dynamics. Now, however, there is a tendency to restrict M. to its first signification. The simple machines, such as the lever, wedge, inclined plane, &c., were known in their applications to the ancients; but the first attempt to explain the principles of their action, and so establish the science of M., seems to have been made by Archimedes in his treatise *De Equiponderantibus*. The publication of Galileo's *Della Scienza Mechanica* (1592), in which the lever, inclined plane, and screw are fully explained, gave the science a powerful impulse; and after this the progress of M. is lost sight of in the progress of the much wider and embracing science of Dynamics

(q. v.). Machinery bears to *M.* the same position which Kinematics (q. v.) does to dynamics, and is therefore a special part of kinematics just as *M.* is a special branch of dynamics. (See *MACHINES*.) Most of the English text-books upon *M.* really treat of dynamics—the name which formerly meant what *M.* here means, being *Applied M.* The most complete book on the subject is Rankine's *Applied M.*

Mechlin (Ger. *Mecheln*, Fr. *Malines*), a city of Belgium, province of Antwerp, on the Dyle, a navigable affluent of the Scheldt, 15 miles S.E. of Antwerp, and 15 N.E. of Brussels by rail. It is the seat of the cardinal-archbishop, primate of Belgium, and has a cathedral of St. Romuald, founded in the 12th c., covering an area of 2 acres, and surmounted by an incomplete tower 345 feet high; the archiepiscopal palace, a grand modern edifice; the churches of St. John and Our Lady, enriched with pictures by Rubens; the town-hall, called the *Beyard*, built in the 15th c.; and a monument to Margaret of Austria (1849). One of the great industrial centres of Europe in the 14th c., *M.* has now lost all its commercial importance, retaining only some of the manufacture of 'M. lace' for which it has been long famous. Pop. (1875) 39,377.

Mecklenburg, the name of two grand-duchies to the N. of Prussia, forming states of the German Empire.—(1) **M.-Schwerin**, by far the larger of the two, is bounded N. by the Baltic, S. by Brandenburg and Hanover, from which it is partly separated by the Elbe, E. by Pomerania and M.-Strelitz, and W. by Lauenburg and Ratzeburg. Area, 5135 sq. miles; pop. (1875) 553,734. Forming part of the N. German plain, and watered by the Warnow and Recknitz, it is to the extent of 70 per cent. arable, 11 forest land, and 9 pasture, the E. half being especially productive of rye, wheat, flax, and tobacco. Along the shores of the Baltic the soil is partly sandy, partly marshy, while inland the country is dotted with numerous lakes, of which the largest are Müritz and Schwerin. There is much rearing of cattle and horses (the latter being of superior value), and extensive industries in fishing and shipbuilding. In 1868 *M.-S.* joined the Zollverein, and in 1875 had a merchant service of 426 vessels (113,656 tons). Schwerin is the capital, and the ports are Rostock and Wismar. Emigration is diminishing the population (1849-64 by 93,000 men). Some of the noble families trace their descent from the Wendish invaders, who conquered the land about the time of the movement southwards of the Germanic peoples. The Grand-ducal-house is the only reigning Slavic family in Europe, and in their full title the grand-dukes style themselves 'Princes of the Wends.' The two duchies hold diets of their 'estates' in common (since 1755), meeting once a year at Malchin and Sternberg alternately. The membership consists of 622 proprietors of Rittergüter ('Knights' estates'), of whom about one-fourth only exercise their privileges, and 40 delegates of towns. The great bulk of the pop., including the entire peasant class, are without any political rights. In 1866-77 the ordinary budget was £102,458, and the public debt, £1,573,345, more than half of which was raised for the construction of railways. The army of the two duchies belongs to the 17th division and the 9th army corps, and comprises two regiments of infantry and two of dragoons, one battalion of jägers, and four batteries of artillery. The bulk of the inhabitants are Lutherans, there being only 1195 Roman Catholics and 3065 Jews. *M.-Schwerin* has two votes in the Federal Council of the Empire, and six representatives in the diet.—(2) **M.-Strelitz** consists of two separate parts, the duchy proper on the E. side of *M.-Schwerin* (area 940 sq. miles; pop. 79,330) and the principality of Ratzeburg, lying between *M.-Schwerin* on the E., and Lauenburg and Lübeck on the W., and touching the Trave, an inlet of the Baltic. Total area 1131 sq. miles; pop. (1875) 95,673. The country and products are the same as those of the larger duchy, with which it has a joint representative chamber. The chief town is New-Strelitz.

History.—The territory was originally inhabited by Germanic tribes, and later by Wendish Slavs of the Obotrite stock, who were subdued and Christianised about 1160 by Heinrich, Duke of Saxony. The country was named Mikilinborg, from the seat (still a village near Wismar) of the Slavic prince Niklot, who was slain by Heinrich, but whose grandson, Heinrich Borwin, having married Heinrich's daughter, eagerly set himself to Germanise the country. *M.* was made a

duchy of the empire in 1348, and divided into the two lines of *M.-Schwerin* and *M.-Güstrow* in 1611. Adolf Friedrich I., of the former line, and Johann Albrecht of the latter, were proscribed (1627) on account of their alliance with Christian IV. of Denmark, on behalf of the Protestant cause during the Thirty Years' War. Wallenstein held *M.* as a fief till 1632, when the banished dukes were restored by the help of Gustavus Adolphus. The many branches into which the ducal line subsequently split were reduced to the two still existing by the Imperial commission of 1701. See the histories of Lützow (3 vols. 1827-35), Boll (2 vols. 1855-56), and Raabe (2d ed. 3 vols. Wism. 1863).

Med'al. See NUMISMATICS.

Medall'ion (Fr. *medaillon*), a bas-relief of a head or figure on a panel of a circular or oval shape. In numismatics the *M.* is the largest known Roman coin, in gold or silver, struck during the empire, either for circulation or to commemorate persons or events.

Medea, the famous sorceress of Greek mythology, was a daughter of the Colchian King Æetes, and either the Oceanid Idyia or Ilcate, daughter of Perses. When Jason came from Thessaly with the Argonauts (q. v.) to fetch the golden fleece, *M.*, whose love he had gained, lulled the watching dragon, and enabled him to seize the prize, after which they left Colchis together. At Iolcos, to avenge the wrong done to Jason, she induced the daughters of Pelias to dismember their father's body and boil it in a cauldron, assuring them that thereby they should renew his youth. After this *M.* and Jason fled to Argos, where the latter fell in love with the king's daughter, Glauke, but *M.* contrived her death by a poisoned robe. At last she killed her own children by Jason, and went to Athens, whence she was forced to flee for plotting against the life of Theseus, but proceeded to Aria, ever afterwards called *Media*. Her story was the subject of tragedies by Euripides, Seneca, Corneille, &c. For the interpretation of the myth of *M.* on the solar hypothesis, see Cox's *Mythology of the Aryan Nations*.

Medell'in, capital of Antioquia, Colombia, S. America, in a beautiful and fertile valley of the Cordilleras, 5030 feet above the sea, has a large transit trade in gold, silver, copper, lead, emeralds, &c. In 1875 the amount of gold and silver despatched from *M.* amounted to 2,403,241 dollars, of which 1,768,368 dollars went to England. A railway is projected from the river Magdalena to *M.*, a distance of 133 miles. Pop. 13,700.

Med'ia (*mada* = 'land' in the cuneiform inscriptions), a territory of ancient Asia, bounded N. and N.E. by the Caspian, E. and S.E. by the desert of Iram, S. by Persia, W. by Assyria, and N.W. by Armenia. It was 550 miles long by 300 broad, had an area of about 150,000 sq. miles, and comprised the modern province of Irak-Ajami, with parts of Kurdistan, Lufistan, Azerbaijan, and Ghilan. Ecbatana (q. v.) was the capital of this district. Its original inhabitants were Turanians, who were conquered at an early date by an Aryan race (the *Mada'i* of Gen. x. 2), entering from Bactria and Sogdiana. The dialect of these Medes was a cognate of Zend, their religion a simple form of Zoroastrianism. They seem to have been masters of Babylon (2458-2234 B.C.), and afterwards to have warred with and been partially subdued by the Assyrians, the first mention of them in the cuneiform inscriptions occurring about 880 B.C. In the 7th c., on the fall of Assyria (q. v.), they founded, under Cyaxares, a mighty empire, embracing all Persia, Assyria, Armenia, and Cappadocia, with a total area of 600,000 sq. miles. But this monarchy was as short-lived as it was vast. Cyaxares' successor, Astyages, was defeated and made prisoner by Cyrus (q. v.) in 558, and henceforth *M.* became absorbed in Persia, in spite of two attempted revolts. See Rawlinson's *History of Herodotus* (vol. i. pp. 401-422), and Grote's *History of Greece* (vol. iii. pp. 301-312).

Media'tor is one who reconciles persons who are at variance. Among the Jews the recognised *M.* between God and the people was the priest, who made an at-onement for them. This sacrificial language is applied in the New Testament to Christ, who is the high-priest and *M.* of the New Covenant, and makes an Atonement (q. v.) for the people. In the Roman Catholic Church the functions of a *M.* also belong to priests, who alone can administer the sacraments, offer sacrifices, and grant absolution, to saints (especially the Virgin Mary), on account of their superabundant merit, and to angels.

Medical Department of the Army. The M. D. of the A. is, next to the commissariat, the most important of the non-combatant sections of the army, the duties of its officers being the maintenance of the health of the troops, their efficient treatment during sickness, and the surgical treatment of the wounded in time of war. In the British army every battalion, when in the temperate zone, has a surgeon and an assistant-surgeon; and when in India or the tropics an assistant-surgeon is added. According to official documents, the army has one surgeon for every 202 men, while the civil population has only one for every 1276 inhabitants. The M. D. of the A. is presided over by the director-general, who is a member of the War Office; a deputy surgeon-general of the sanitary branch, a deputy surgeon-general of the statistical branch, a surgeon-general of the medical branch, four surgeons-major, and a senior clerk. The different grades are surgeon, surgeon-major, deputy surgeon-general, and surgeon-general. Candidates for admission to the service must be not under twenty-one nor above twenty-eight years of age; a board of medical officers must determine as to physical fitness, and they must be registered practitioners, possessed of two diplomas or licences, one to practise medicine and the other surgery in Great Britain or Ireland. After passing a professional examination by the examining board, they are required to attend a course of practical instruction at the Army Medical School at Netley on (1) hygiene, (2) clinical and military medicine, (3) clinical and military surgery, and (4) pathology of diseases and injuries incident to military service. After a satisfactory examination on these subjects the candidate is eligible for a commission as surgeon. By a Royal Warrant, of 28th April 1876, respecting medical officers in the army, a complete revolution has been effected, and a short-service system introduced. It provides, *inter alia*, as follows:—On the completion of ten years' commissioned service, unless the surgeon be specially selected for further employment in the A. M. D.; or if he be unwilling to continue to serve therein, his services shall be dispensed with, and he shall be entitled to receive, in lieu of all pension or retirement, pensions for wounds excepted, the sum of £1000. Every year the commander-in-chief, on the recommendation of the director-general of the A. M. D., may select, with the approval of the secretary of state, a number of surgeons, not exceeding six, who shall be retained in the service, and shall be promoted after twelve years' service on full pay to the rank of surgeon-major. All promotion from the rank of surgeon-major to that of deputy surgeon-general shall be given for ability and merit upon the selection of the commander-in-chief, with the approval of the secretary of state, and the grounds of such selection shall be stated in writing and recorded in the department. The full pay per diem of a surgeon, on appointment, is 13s. 8½d.; and, after ten years' service, 17s. 6d.; of surgeon-major, according to length of service, from £1 to £1, 5s.; of deputy surgeon-general, from £1, 10s. to £1, 17s.; and of surgeon-general, from £2 to £2, 10s. The non-effective pay of the above-named officers, is, respectively 10s.; from 11s. to £1; from £1, 1s. to £1, 5s. 6d.; and from £1, 10s. to £1, 17s. 6d. A medical officer retiring after full-pay service of twenty-five years and upwards may, if recommended for the same by the head of his department, receive a step of honorary rank, but without any consequent increase of pay. Medical officers shall have a right to retire on half-pay after twenty years' service; medical officers of the rank of surgeon-major, or surgeon, shall be placed on the retired list at the age of fifty-five, and all surgeons-general, and deputy surgeons-general, at the age of sixty years. Good-service pensions are awarded to the most meritorious officers, and six of the most meritorious officers of the A. M. D. are selected as honorary physicians, and six as honorary surgeons to the Queen.

Medical Department of the Navy. The M. D. of the N. is presided over by the director-general and the medical officer at the Admiralty. The various grades in the service are surgeon, staff-surgeon, fleet-surgeon, deputy inspector-general of hospitals and fleets, and inspector-general of hospitals and fleets. The regulations for obtaining a commission in the M. D. of the N. are similar to those for the army. After completing three years' full-pay service, surgeons are allowed to be examined for the rank of staff-surgeon, but no surgeon can be promoted to the rank of staff-surgeon until he shall have served five years, two of which must have been in a ship actually

employed at sea. Promotion to the rank of fleet-surgeon is open to officers for distinguished or special service, although twenty years on full pay may not have been completed; such fleet-surgeons have 16s. a day half-pay. Fleet-surgeons rank with commanders, according to date of commission, and they are appointed to the flag-ships of commanders-in-chief on foreign service. The full pay per diem of a surgeon is, according to length of service, from 11s. to 17s.; of a staff-surgeon, 18s. to £1, 2s.; of a fleet-surgeon, from £1, 3s. to £1, 10s.; of a deputy inspector-general of hospitals and fleets, £1, 11s. to £1, 18s.; of inspector-general of hospitals and fleets, from £2, 5s. to £2, 10s. The half-pay of the above-named officers respectively is from 6s. to 11s., from 11s. to 14s., from 16s. to 18s. 6d., from £1, 1s. to £1, 7s., from £1, 11s. to £1, 18s. Retirement is provided for, according to age and service, under special regulations.

Medical Practitioners. Qualified M. P. are entitled to be registered as such on payment of a fee of £2 in respect of qualifications obtained before January 1, 1859, and of £5 in respect of qualifications obtained since that date. Every person possessing one or more of the following qualifications is entitled to be registered: Fellow, Member, Licentiate, or Extra-Licentiate of the Royal College of Physicians of London, of Edinburgh, and of Ireland; Fellow, or Member, or Licentiate in Midwifery of the Royal College of Surgeons of England; Fellow or Licentiate of the Royal College of Surgeons of Edinburgh, of the Faculty of the Physicians and Surgeons of Glasgow, and of the Royal College of Surgeons in Ireland; Licentiate of the Society of Apothecaries, London, and of the Apothecaries' Hall, Dublin; Doctor, or Bachelor, or Licentiate of Medicine of any university of the United Kingdom; Licentiate in Surgery of any university in Ireland; Doctor of Medicine, by doctorate granted prior to 2d August 1858 by the Archbishop of Canterbury; Doctor of Medicine of any foreign or colonial university or college, practising as a physician in the United Kingdom before 1st October 1858, who has taken such degree after regular examination. Persons who were practising medicine prior to 1815, and those who held appointments as surgeons or assistant-surgeons in the army, navy, militia, or East India Company prior to 1858, and persons practising on foreign or colonial diplomas or degrees prior to 1858, if such have been obtained after regular examination, are entitled to be registered. Registration is not compulsory, but unregistered M. P. cannot recover charges for professional services or medicines in a court of justice; nor can they hold any appointment in the military or naval service, or in the mercantile marine; nor can they hold any public medical appointment, nor a medical appointment in any institution not supported wholly by voluntary subscriptions; nor can they sign any medical certificate required by any Act of Parliament. The names of M. P. may be removed from the registration roll on account of unprofessional conduct, and M. P. are liable to prosecution for negligence and malpractice. The principal appointments held by registered M. P. are as follows: surgeons in the army, the navy, and the Indian army, and in passenger and merchant ships; medical inspectors of merchant and passenger ships, and of seamen; prison and factory surgeons; medical officer to the Local Government Board; medical visitors of lunatics; medical officers under the Contagious Diseases Acts, and in parishes and unions; public vaccinators; vaccination officers; analysts under the Adulteration of Food Acts; medical officers of health, &c., &c. The principal statutes affecting M. P. are—The Medical Act, 1858, amended 1860, 1873, and 1876; Incorporation of the General Council, 1862; Amendment of Medical Acts so far as relates to London University, 1873; Colonial Practitioners, 1868; The Apothecaries Act, 1815, amended 1874; the Practice of Anatomy, 1832, amended 1871; Vaccination, 1867, amended 1871 and 1874; Medical Witnesses at Coroners' Inquests, 1836, amended 1837; The Sale of Poisons, 1868, amended 1869; The Sale of Arsenic, 1851; The Sale of Poisons in Ireland, 1870; Lunacy Acts 1838, 1840, 1845, 1853, 1855, 1860, 1862; The Contagious Diseases Act, 1866 and 1869; Surgeons in Passenger Ships, 1855; Surgeons in Merchant Ships, 1854 and 1867; Prison Surgeons, 1865; Factory Surgeons, 1844; Births, Deaths, and Marriages, 1836 and 1874; Public Health in England, 1875; Public Health in Scotland, 1867; Public Health in Ireland, 1874; Adulteration of Food, Drugs, &c., Acts, 1860 and 1872; Local Government

Board Act, 1871; Local Government Board (Ireland) Act, 1872; Act to Remove Restrictions on Granting Qualifications for Registration on the Ground of Sex, 1876; The Medical Practitioners Act, 1876; The Vivisection Act, 1876.

Medical School, Netley. The military M. S. at N. is attached to the Royal Victoria Hospital, which is the great invalid depôt for the whole army. The director-general of the army medical department is president of the senate, the other members of the senate being the physician to the council of India, the director-general of the medical department of the navy, the professors of the army medical school, and the principal medical officer at Netley, *ex officio*. There are four professors and assistant professors, who teach military surgery, military medicine, military hygiene, naval hygiene, and pathology, naval hygiene being taught by an additional assistant professor. Successful competitors for appointments in the army, navy, and Indian medical services are required to attend, subsequently, at Netley a course of practical instruction in the duties they will have to perform in the army and navy. The course lasts four months, after which an examination is held to ascertain the progress made by each candidate. The candidates also attend the wards of the hospital to study the diseases of the invalids, the system of recruiting, and the modes of keeping the army medical returns and records. During his service at Netley each candidate receives an allowance of 5s. per diem, and 2s. per diem for lodging money, if quarters are not found him. He wears uniform, attends the medical staff mess, and is under the usual military discipline. At the conclusion of the course, the candidate, if he passes the examination satisfactorily, is eligible for a commission as surgeon.

Medici (pron. *Medichi*; Fr. *Médicis*), an Italian family that first gained distinction in the 14th c., when Giovanni de M. rendered valuable aid to Walter of Brienne, Duke of Milan, especially by capturing the fort of Scarperia. His descendants Alamanno, Salvestro—one of the best magistrates Florence ever had—and Veri de M., added lustre to the name; but the family star seemed on the wane when Antonio was executed in 1397. Giovanni de M., however, a rich merchant belonging to a humble branch of the family, restored its fortunes, and dying in 1429 left two sons, Cosmo and Lorenzo, the former of whom, while continuing his father's business as banker and merchant, mainly directed his efforts to the acquisition of supreme power in Florence. Concealing a great ambition behind careless luxury and munificence, twice exiling himself that the Florentines might find how necessary he was to them, he finally established himself as the most powerful ruler in Italy. He became the princely patron of science and all liberal arts. From the ruins of the falling Eastern Empire his agents rescued priceless literary treasures—Latin, Greek, and Hebrew MSS., with which he formed the basis of the Laurentian Library; the most prominent of those engaged in reviving ancient learning were invited to live in his palace; when Constantinople was captured in 1453 the wisdom of the East was laid at his feet, and his school of philosophy, the first established in Europe, restored to Plato the eternity of fame he had nearly lost; he raised art from the dust to a throne—in his day worked Masaccio, the Piselli, the Lippi, Binozzo, Sandro, Ghirlandaio, with younger and greater men; and for him Donatello—Pygmalion-like with his Zuccone—wrought daily miracles in marble, Brunelleschi reared the Duomo that Vasari feared would make the heavens envious, and Ghiberti cast the bronze doors in San Giovanni which Michael Angelo thought fit for the gates of heaven. With all the powers of gold he bought the hearts and the liberty of his fellow-citizens; with wise precaution, moreover, he married his children to representatives of the leading families around him; and he died with the title of Pater Patriæ. The same magnificent policy was pursued by Cosmo's grandson, Lorenzo, who succeeded a weak father in 1467. His brother Giuliano, at first associated with him in the government, was assassinated in the Church of the Reparata, and to show the popularity of the family, it may be mentioned that when after this deed several hotheads of the Pazzi faction ran through the streets crying 'Liberty and the People,' the mob strung them up, shouting *Palle, Palle (the Balls, the Medici sign)*. Not without strife with Pope Sixtus IV., Ludovico Sforza, Ferdinand of Naples, and others, Lorenzo yet devoted most of his years to the cultivation of science and literature. He himself wrote verses

which Mirandola declared better than Dante's; he would read Plato with his philosophers in the morning, and sing his own obscene songs to the same applauding philosophers in the evening. The classical taste made fashionable by Cosmo had now gone so far that none would write in Italian, or in anything but the best Latin or Greek. Cardinal Bembo writes to a friend that he had better not read St. Paul's Epistles, for their barbarous style might corrupt his taste. Lorenzo effected some improvement here. Still, however, he continued the collection of ancient MSS., and the value of his services to European literature in this work is beyond all computation. He collected art antiquities likewise with great assiduity, and set apart his gardens adjoining St. Mark's for the study of the antique. All that could please the intellect and the senses was drawn to Florence; it had become a pagan city of delight, wherein life was a continual carnival. This was the state of matters amid which Leonardo da Vinci was dreaming his dreams of beauty, Benvenuto Cellini imprisoning his genius in wondrous gold cups and boxes, and Michael Angelo beginning to draw men as gods, upon all which the strippling Macchiavelli looked with the glance of a gamester, and Savonarola with tears in his eyes.

Lorenzo died April 8th, 1492. His son Giovanni, made cardinal at the age of thirteen, became Pope Leo X., and continued the patron of letters and art. Pietro, who succeeded Lorenzo, sacrificed Florence to Charles VIII.; but Leo again restored the family to power. Cosmo, not a direct descendant of Lorenzo, became Grand Duke of Tuscany about 1539, and founded a short dynasty, which ended in 1737. The policy of the M. was ever to indulge the inclinations of the people, and, blinding them to national interests with present pleasures, to fix firmly in their midst the foundations of an absolute monarchy. As princes they were lavish and magnificent; but as men they were, with scarcely an exception, unscrupulous, licentious, cruel. While their sun was in the meridian, men were content to take splendour for worth; but when it sank it left behind a night of corruption and fear. See Roscoe's *Life of Lorenzo de M.* (a blindly partial panegyric), and his *Life of Leo X.*; Fabroni's *Magni Cosimi Medici Vita* (Pisa, 1789, a careful work); Galluzzi's *Storia del Granducato di Toscana sotto i M.* (Flor. 1781). For an antidote to Roscoe see Sismondi's *Histoire des Républiques Italiennes* (Geneva, 1807), Trollope's *Commonwealth of Florence* (4 vols. Lond. 1865), Perrens' *Histoire de la Littérature Italienne* (Par. 1867); and Symonds' *Renaissance in Italy* (Lond. 1877).

Medici'na, a thriving town of N. Italy, province of Bologna, 28 miles N. by W. of Imola, was formerly surrounded by walls, and has an artesian well in one of its squares. It is built on the site of the ancient *Claterna*, and possesses many fine antiquities. Pop. (1874) 11,355.

Medicinal Plants are very numerous, and belong to the most widely different orders; and, in some orders, particular properties are prevalent. Important properties are often characteristic of a very limited group of species, as in the case of the *Cinchonas*. In almost every country, plants peculiar to the district are used by the natives for medicinal purposes. The value of many having been fairly established by long experience, they have been adopted in other countries, and transplanted for cultivation. In many cases, however, plants so transplanted have not retained in full degree their original properties, owing probably to variations in climate and soil. The parts endowed with the medicinal properties may be used in the form of powder, or the active principles may be extracted by infusion and decoction, or by the aid of alcohol or ether. The more active ingredients may also be separated in the form of alkaloids. Official M. P. are those which have a place accorded them in pharmacopœias, and in the practice of educated medical practitioners; but there are many valuable plants which are not so classified. The cultivation of M. P. is carried on to a great extent at Mitcham, near London; and Cinchona trees have been recently introduced into India and successfully cultivated there for the production of quinine. See *M. P.* by Bentley and Trimen (Lond. 1877).

Medicine and Surgery, History of. The early H. of M. is involved in obscurity; but the first systematic treatises appear to have been compiled in China and India. Cholera, or a disease resembling it, was described in China, 2500 B.C., by

the very name which it now bears, viz., *kuo-luan*. The systematic Hindu works on medicine appear to have been compiled and arranged before the corruption of the primitive mythology. The Ayur-veda is allowed to be the most ancient system of medicine, but the age in which it was written is not known. It was probably compiled about the period of the Manu code of laws, 900 B.C., but fragments only are now procurable. The Charaka is the most ancient existing medical work of the Hindus, and may be compared to the works of Hippocrates, who probably derived some of his observations from this source. The work is arranged in the form of dialogues between the master and his pupils, and consists of eight books. The Susruta, supposed to be of later date, is more systematic than the Charaka, and is divided into six books, as follows:—(1) Medical doctrine, (2) Pathology, (3) Anatomy, (4) Therapia, (5) Doctrine of Antidotes, and (6) The Supplementary Section. Medicine was practised by the Vaisya caste, and it was said that 'the Brahmin learned the medical Shastres for his own interest and character; the Kshatriya, for the benefit of his health; and the Vaisya, for his subsistence, as he was alone allowed to receive recompense from the sick.'

It is probable that medical science extended from India to Upper Egypt, and from thence to Lower Egypt; for the natives of India had, from time immemorial, commercial relations with the Gulf of Aden and the Red Sea ports. The Egyptians, according to Herodotus, successfully cultivated the art of medicine, and, in practice, they divided it into distinct branches. The writings of Moses show that the Jews had paid considerable attention to medical science, more especially the highest branch of it, viz., the preservation of health, and the prevention of contagious diseases by isolation and cleanliness. The Chinese, Hindus, Egyptians, and Jews paid great attention to hygiene, and the Mosaic code of sanitary laws is much superior, in some respects, to any that have since been compiled. Cheiron, the centaur, a native of Thessaly, is fabled to have introduced the art of medicine among the Greeks, probably from Egypt, and to have instructed the heroes engaged at the siege of Troy in the art. Æsculapius (q. v.), a native of Epidaurus, and a disciple of Cheiron, is spoken of in the Homeric poems as 'the blameless physician,' who went about Greece healing diseases and raising the dead to life. After his death, divine honours were paid to him, and temples were erected to him in various parts of Greece. Two of his sons accompanied the Greeks to the Trojan war. For several centuries after the Trojan war, medical practice was confined to the Asclepiades (q. v.), the reputed descendants of Æsculapius, and the temples dedicated to him were employed, to a certain extent, as schools of medicine. According to Herodotus, the Greeks possessed more medical skill than the Egyptians in the time of Darius, the son of Hystaspes. Pythagoras, who lived 600 B.C., was the first to bring the principles of philosophy to bear upon the study of medicine, and to raise it to the dignity of a science. His pupils, Democritus and Heraclitus, paid special attention to comparative anatomy, and, probably, first dissected the human subject. Their contemporary, Herodicus, first introduced the practice of gymnastic exercises as a part of hygiene and medical treatment.

The one who contributed more than any other single individual, either of his own or of any other age, to the advancement of both medicine and surgery is Hippocrates (q. v.), who lived about 400 B.C. Taking experience as his guide, he carefully observed nature, and after collecting facts, he sought to deduce the general laws by which these facts might be explained. In his writings we meet with the first traces of physiological science. His reputation principally rests upon the improvements which he effected in the practice of medicine, yet he was evidently skilled in the art of surgery. He is said to have been the inventor of the art of bandaging; he used the trepan, and also complicated machines in reducing dislocations, and he tapped the chest in cases of hydrothorax. His sons, Thessalus and Draco, and his son-in-law Polybius, were the founders of the medical sect or school which was called the Hippocratean or Dogmatic School.

The successors of Hippocrates were, for a long time, content to follow the course of their master, and to yield unqualified assent to all his doctrines. Diocetes of Carystus obtained great celebrity for his learning and skill. He paid great attention to anatomy; the study of the vascular system; the nature of the respiratory process, and the appearances of the urine in disease.

He also invented an instrument for the extraction of darts. Praxagoras of Cos was the first to distinguish the arteries from the veins, and to recognise the state of the pulse as an index of the condition of the vital powers. His surgical practice was bold rather than prudent, as, in cases of colic, he opened the abdominal cavity. Aristotle made great advances in natural history and anatomy. He was the first to point out the origin of all the blood-vessels in the heart, and he gave the name of aorta to the largest artery in the body.

The next important epoch in the H. of M. was the establishment of the Alexandrian school of philosophy by Ptolemy Soter, about 300 B.C., where students of medicine enjoyed many privileges, the most important being the opportunity of dissecting the human subject, the bodies of criminals having been given up for that purpose. The most celebrated anatomists of that period were Erasistratus (q. v.) and Herophilus, who discovered the functions of the nervous system and the lacteal vessels. At about this time the profession of medicine was divided into the three departments of dietetics, pharmacy, and surgery, each division being exercised by separate individuals. The surgeons of Alexandria attained considerable dexterity, and operated for stone in the bladder with the *apparatus minor*, as described by Celsus; and Ammonius, about this time, invented an instrument for crushing the stone in the bladder. The Alexandrian physicians formed themselves into a distinct sect called the *Empirics*, the founder of the sect being Serapion, a pupil of Herophilus. The Dogmatists maintained that the treatment of disease should be based on a knowledge of the healthy structure and functions of the body, and of the influence of remedies, and the effects of disease upon it; while the Empirics maintained that such knowledge was unnecessary and unattainable, and that simple experience should be the only guide to practice. For some centuries the progress of medicine was arrested by the controversies of the rival sects.

The next important epoch in the H. of M. was the Roman. Archagathus, a Peloponnesian surgeon, settled at Rome about 200 B.C., but his practice was so severe and so unsuccessful that he was banished. About a century after, Asclepiades, of Bithynia, acquired a great reputation, from the strict attention which he paid to the comfort of his patients. He is said to have been the first who divided diseases into acute and chronic. He was succeeded by his pupil Themison, of Laodicea, who founded a sect called *Methodics*, who adopted a middle course between the *Dogmatists* and the *Empirics*, and were the prevailing sect for the first two centuries of our era. Among the adherents of this sect were Soranus and C. Aurelianus, some of whose writings have come down to us. The *Dogmatists* broke up, finally, into various sects, the chief of which were the *Pneumatics*, represented by Areteus (q. v.), of Cappadocia, and the *Eclectics*, of whom Archigenes, of Apamea, who practised in Rome at the time of Trajan, was the most celebrated.

The most remarkable writer of this age is Aulus Cornelius Celsus (q. v.), the first native Roman practitioner whose name has been handed down to us, who, in his work *De Medicinâ*, gives a sketch of the H. of M. He defends the study of anatomy against the Empirics, gives excellent surgical precepts regarding lithotomy, trepanning, the treatment of fractures and dislocations, the operation for cataract by depression, and the reduction of hernia. He was the first to recommend the application of ligatures to bleeding vessels. Among physicians of this age may be mentioned Andromachus, the inventor of the theriaca; Pliny, the naturalist; and Dioscorides. Heliodorus and Antyllus, celebrated surgeons of the reign of Trajan, contributed much to the advancement of surgery. The latter speaks of the operation for cataract by extraction, gives directions for the operation of tracheotomy, and the radical cure of hydrocele by incisions into the tunica vaginalis.

The writings of Claudius Galenus (q. v.), commonly called Galen, who was born at Pergamus in the year 130 A.D., form an epoch in the H. of M., and were universally acknowledged as ultimate authority until the 16th c., when they were attacked and publicly burned by Paracelsus (q. v.). Galen's contributions to medical science were so superior to those of his predecessors from the time of Hippocrates, and to those of his contemporaries, that they acted for centuries as a check to all attempts at further improvement. Paulus Ægineta lived about the middle of the 7th c., and was the last physician of any note of the Greek school of medicine.

The next epoch in the H. of M. is the advent of the Arabian school. After the conquest of Alexandria in A.D. 641, by the Moslems, the writings of Hippocrates and Galen were translated into Arabic, and enlarged by copious commentaries. About the end of the 8th c. a medical college was founded at Bagdad, and public hospitals were built. Rhazes, who lived about the commencement of the 10th c., was the first writer of note, and the first to describe smallpox and measles. Avicenna (q. v.), who flourished in the 11th c., and was called 'the prince of physicians,' wrote the *Canon Medicinæ*, a cyclopædia of medicine and the collateral sciences. Albucasis, who died A.D. 1112, was the most celebrated of the Arabian surgeons, but his practice was attended with unnecessary severity. Hæmorrhage from a bleeding stump was arrested by dipping the part into boiling pitch, a practice continued by Arabs till the present day. Avenzoar and Averhoës (q. v.), though natives of Spain, wrote in the Arabic language. The Arabian school made no advances in surgery, but did good service to medicine by the correct description of several diseases, the first record of new and important ones, the introduction of new articles into the *materia medica*, and by making known the first elements of pharmaceutical chemistry, as the art of distillation, and the preparation of various metallic oxides and salts.

After the extinction of the Arabian school an interval of 300 years, from the 12th to the 15th c., elapsed, during which the science of medicine fell into the lowest state of degradation. In the beginning of the 11th c. a medical school was established at Salerno, in Italy, the earliest establishment where regular medical diplomas were granted to candidates, after they had passed through a prescribed course of study, and been subjected to certain examinations. In 1163, the Council of Tours prohibited the clergy from undertaking any bloody operation, and surgery was abandoned to the laity. The Salerno school was gradually eclipsed by the medical schools at Bologna, Padua, Vienna, Paris, &c., in the 14th and 15th centuries. Mondini publicly dissected two human bodies at Bologna in 1315. Gilbertus Anglicanus, who lived about the beginning of the 14th c., is the first English surgeon whose name has been handed down to us. The 15th c. gave birth to Linacre, who, after studying at Oxford, proceeded to Bologna, Florence, Rome, Venice, and Padua, and afterwards founded the London College of Physicians. During the 15th c. syphilis first broke out in Italy; the sweating-sickness first appeared in this country, and hooping-cough and scurvy were first described. The sect of *chemical* physicians arose, headed by Paracelsus, who publicly burnt the writings of Galen, and who maintained that all the phenomena of the living body may be explained by the same chemical laws as those which rule inorganic matter; but the chemists of that age did nothing to advance medicine beyond adding several valuable metallic preparations to the *materia medica*.

At the commencement of the 16th c. surgery was still in a degraded condition; but at length Antonio Beneveni, a Florentine physician, insisted that the compilations of the ancients and the Arabians should be relinquished for the observations of nature. The labours of Vesalius gave birth to anatomy, and the art of surgery assumed a higher rank. The most celebrated surgeon of the 16th c. was Ambrose Paré, a native of Laval, who revived the use of the ligature in the treatment of hæmorrhage. At this time the practice of surgery was associated with that of the barber, and the barber-surgeons continued to practise for a period of nearly two hundred years. The 16th and the 17th c. was the epoch of many celebrated anatomists and physiologists, who gave a fresh impulse to medicine and surgery, the most celebrated of whom were Eustachius, Fallopius, Aëlius, Harvey, Rudbeck, Fabricius, Glisson, Bartholin, Malpighi, Willis, Bellini, Hooke, Sylvius, and Marcus Aurelius Severinus, the restorer of operative surgery. The most celebrated English surgeons of the 17th c. were Richard Wiseman and William Harvey (q. v.), whose name is rendered immortal by his discovery of the circulation of the blood, the benefits of which, as regards the science of medicine and surgery, can scarcely be over-estimated. Sydenham was unquestionably the greatest physician of the time, and gave an impetus to medical science which extended over Europe. During this period, chemistry was separating itself from alchemy, and advancing to the position of a science, and, by its combination with physiology, gave rise to a new sect of physicians called the *Humoralists*,

who considered that diseases were referrible to certain fermentations which took place in the blood, and that certain *humours* were naturally acid and others naturally alkaline, and that as each predominated, certain specific diseases were the result, which were to be removed by the administration of antidotes. They were soon succeeded by the *mathematical* physicians, or the *iatro-mathematical* school, represented by Borelli, Sauvages, Keill, Jurin, Mead, and Freind, who applied the laws of mechanics to the explanation of all the phenomena of the living body. These rival sects were followed by the *vitalists*, headed by Van Helmont (q. v.), who held that in the living body there is a principle which presides over and directs all the processes of the living body, and is directly opposed to the influence of chemical and mechanical agents.

During the early part of the 18th c. Boerhaave, and his pupil, Van Swieten, were the most eminent teachers of medicine, and they adhered to the leading principles of the *vitalist* school. Haller (q. v.), the Swiss anatomist, and the father of modern physiology, maintained the doctrine that irritability and sensibility are specific properties of the muscular and nervous systems, a doctrine controverted by Professor Whytt, and Porterfield of Edinburgh. Cullen (q. v.), of Glasgow, advanced the science of medicine more by his classification of diseases than by the formation of the Cullenian school of medicine. With him and his former assistant and acrimonious rival, John Brown, the founder of the Brunonian system of medicine, theoretical medicine ceased in Europe. Since that time physicians have not been guided by any general medical theory. The 18th c. was rich in distinguished surgeons. The Dutch surgeons, Ruysch, the anatomist, Roonhuysen, the obstetrician, and Raw, the lithotomist, concealed their modes of operation, but their secret practice was discarded by their successors. France produced two surgeons of extraordinary genius—Petit and Desault; while Great Britain can boast of Cheselden, the lithotomist, the two Monros, Cowper, White, Pott, Hawkins, Smellie, and the eminent John Hunter; Italy of Lancisi and Morgagni; and Germany of Heister and Sæmmering.

The present century may be considered as the epoch of physiological experiment and clinical observation, and the list of distinguished physicians and surgeons, of anatomists, physiologists, pathologists, and hygienists, is too extended even for enumeration. In no former epoch of the healing art have so many sure advances been made in medicine, surgery, and the collateral sciences. By the aid of the microscope, chemical re-agents, galvanic and electric appliances, intimate pathology, and physiology, as well as the diagnosis of healthy and morbid conditions, in the living body, are being advanced with the most astonishing rapidity. By the aid of anæsthetics, recently introduced by Sir James Simpson (q. v.), the most formidable operations may be performed without pain, and by the antiseptic system of surgery introduced by Professor Lister of Glasgow and Edinburgh, the dangers resulting from them are reduced to a minimum. The most marked triumph of medicine in the present century has been the application of vaccination, the discovery of Jenner (q. v.). Within recent years the doctrine of *contagium vivum*, and its application to medicine has been, and is still being investigated with the most wonderful results. The virus of vaccinia, small-pox, sheep-pox, diphtheria, erysipelas, and glanders, has been proved to consist of minute particles having the character of micrococci, and it is highly probable that the connection of all the specific fevers, such as typhus, typhoid, scarlet-fever, measles, and the rest of the contagious diseases, with pathogenic organisms, will soon be demonstrated. The germ problem, as applied to disease, has been investigated by Dr. Burden Sanderson, Dr. W. Roberts, Professor Lister, and most recently by Professors Tyndall and Cohn, and in 1876 and 1877 by Dr. Braidwood and Mr. Vacher, on behalf of the British Medical Association. The spirit of research is equally characteristic of all the medical schools of Europe; and America has made many valuable contributions to medicine and surgery. State medicine, which has for its object the preservation of the public health, is gradually assuming an important position, and will probably soon be represented by a Minister of Health in all civilized countries.

Medick (*Medicago*), a genus of *Leguminosæ*, of which the most important species has already been described under *Lucerne* (q. v.). Another of considerable cultivation as a fodder plant

is the Black M. or Nonsuch (*M. lupulina*), commonly sown in admixture with grasses and clovers, and amongst farmers frequently termed trefoil from confusion with *Trifolium procumbens* and *T. minus*. There is little doubt that this plant has the best claim to the name Shamrock (q. v.). It is a very common British species. The genus *M.* differs from *Trifolium* by having its pod spirally curved or coiled, instead of being small and nearly enclosed in the calyx. It consists of over forty species, principally Mediterranean, but now widespread through the world as weeds. Many have the pod beset with hooked spines, which facilitate their dissemination. See HEDGEHOG PLANTS.

Mediæte Lingua, in Eng. law, is a jury half English half foreign, to try a question between a foreigner and a Denizen (q. v.).

Medina (Arab. *Medinat-el-Nebi*, 'city of the prophet'), a town of Arabia, in the Turkish vilayet of Hedjas, 270 miles N. of Mecca, and 130 N.E. of the sea-port of Yambu. The inner town, built in an oval 2800 paces in circumference, at the north-western point of which rises the citadel, is surrounded by a wall, 40 feet high, with thirty towers, and pierced by three gates. Beyond this extend the suburbs. The chief building of *M.* is its grand mosque, El Haram ('the inviolate'), erected on the site of Mohammed's house. It is 420 feet long by 340 broad, has a vaulted roof supported by 400 pillars, and in its S.E. angle contains the reputed tombs of Mohammed and the califs Abu-Bekr and Omar. Some minor mosques, and the subterranean aqueduct of Suleiman II. (16th c.), bringing water from Koba, 2½ miles distant, are the only other noteworthy objects. *M.* has even less trade than Mecca, but grain and dates are exported to Egypt by way of Yambu. Estimated pop. 16,000. The *Iathrippa* of Ptolemy, *M.* is famous as the asylum (622) of Mohammed, and the scene of his death. It was taken by the Wahabis (1804), retaken by the Egyptian pasha (1818), and, along with Hedjas, was ceded to Turkey (1867). It is now the seat of a Turkish pasha of the first rank.

Medina de Rioseco ('*M.* of the dry stream'), a decayed town of Spain, in the province of Valladolid, on the right bank of the waterless Sequillo, 21 miles N.W. of Valladolid. It still possesses four monasteries, three churches (one a noble Gothic building, with a gorgeous high altar and twenty-four bells), a castle, and two hospitals; and in the middle ages was the great commercial centre of Spain, its cloth and linen winning for it the title of *India-Chica* ('India Minor'). Here the French under Bessières defeated Cuesta, July 14, 1808. Pop. 4500.

Medina-Sidonia (Arab. 'city of Sidon,' the Phœnician *Asido*), a town of Spain, in the province of Cadiz, 23 miles E.S.E. of that city, contains a fine Gothic church and the ruins of the castle of the Dukes of M.-S. (a branch of the Guzman family), and has a manufacture of *alcarrazas*, or porous water-coolers. Pop. 10,800.

Medinet-el-Fayûm. See FAYUM.

Meditatio Fu'ga, a term of Scotch law, denoting an intention on the part of any one to abscond, in order to avoid the jurisdiction of a court of law. A creditor of any one, on making an oath before a magistrate that his debtor is *in meditatione fugæ* to avoid payment, will get a warrant to apprehend the debtor and have him examined. Should the accusation appear to the magistrate to be true, he will grant a warrant to imprison the debtor until he find security *judicio sisti*. But should the creditor have proceeded on insufficient grounds, he will be liable in damages, and even the judge may be so also, if he have acted incautiously. In English law see DEBTORS, ABSCONDING.

Mediterranean Sea, so named on account of its position between the continents of Europe, Asia, and Africa. It was called by the earlier Greek poets simply the 'Sea'; by later prose writers, both Latin and Greek, the *inner* or *internal* Sea, in opposition to the Atlantic, or *external* Ocean, and also 'Our Sea.' The name 'Mediterranean' is not classical, occurring first in Solinus, but it has become the recognised appellation throughout Europe in modern times. The *M. S.* is 2200 miles long and 1200 broad, from the bay of Tunis to that of Sidra. Its area is 977,000 sq. miles. Penetrated by the peninsulas of Italy and Greece, and partly enclosed on the W. by that of Spain, it is of a most irregular shape, and bears various names in different parts, e.g., the Tuscan, Ionian, Adriatic, and Ægean seas. Its chief inlets are, in Europe, the Gulfs of Lyons, Genoa, Taranto,

Lepanto, Koron, Kolo-Kythia, and Salonica; in Asia, Adramyti, Smyrna, Adia, and Askanderum; in Africa, Sidra and Cabes. It receives rapid currents both from the Atlantic, through the Strait of Gibraltar in the W., and from the Black Sea, through the Dardanelles in the E., besides draining the Nile, Rhone, Po, Ebro, &c. Owing, however, to the Alps and Pyrenees sheltering it from the cold N. winds, and to its instant exposure to the hot winds of Africa, the *M.* has a temperature 3° 05' F. higher than the Atlantic. The temperature, it was ascertained by the expeditions of 1869-70, is uniform below 100 fathoms, where it becomes fixed about 55°. Its water contains about one-sixth or one per cent. more salt than that of the Atlantic, because of its more rapid evaporation. The depth in the Strait of Gibraltar is 5500 feet, but between Cape Bon and Sicily, where a bank nearly divides the sea, it is only 200, and in some parts diminishes to 40. The currents and tide, both of slight character, are greatly marked by the prevailing winds, which in spring are S.E. and S.W., and for the rest of the year N.E. and N.W. The highest tide in the Gulf of Venice is between 5 and 6 feet; on the coasts of Egypt it is only 1 foot. The Suez Canal (q. v.) connects the Mediterranean with the Red Sea. There are valuable tunny, anchovy, pilchard, sardine, and mackerel fisheries in the Mediterranean, which also furnishes large quantities of red coral. See *The Mediterranean*, by Rear-Admiral W. H. Smyth (Lond. 1854).

Medjidi'eh, a town in the Dobrudscha, European Turkey, nearly midway between Tchernavoda on the Danube, and Küstendjion on the Black Sea, and a station on the railway uniting these places. It was founded in 1859, and named in honour of Abdul Medjid. *M.* owes its origin to the immigration of Tartars from the Crimea and Kuban steppes, after the close of the Crimean war, when Russia began to deal ruthlessly with her Mussulman subjects. It is now reckoned the Tartar capital of the Dobrudscha, and has a pop. of 20,000. The inhabitants, chiefly engaged in agriculture, are an industrious and temperate race.

Medlar (*Mespilus*), a genus of *Rosaceæ* closely related to *Pyrus*. There is only one species, viz., *M. Germanica*, a low deciduous-leaved tree, native of Europe and W. Asia, and perhaps indigenous in the extreme S.E. counties of England. Its fruit, which is about the size of a very small apple, ripens in November, and can be either made into a jelly, or eaten raw when in a state of incipient decay (see Shakespeare, *As You Like It*, Act iii. Scene 2). It then has a peculiar flavour and acidulous taste, relished by some, but disliked by others.

Medull'a Oblonga'ta is the continuation of the spinal marrow into the base of the Brain (q. v.). It is connected with the cerebellum by the *pons varolii*. Its injury is fatal.

Medull'ary Rays. See EXOGENOUS PLANTS and PITH.

Medull'ary Sarco'ma. See CANCER.

Medu'sa, the name applied to the common kinds of Jelly-fishes (q. v.), and erroneously to the free-floating reproductive buds of Zoophytes (q. v.), which closely resemble jellyfishes in appearance. The *Meduside* is an order of *Hydrozoa* (q. v.), represented by the true jelly-fishes. As now constituted in modern zoology, it represents that portion of the old group *Aculephæ* (q. v.), which included the *Gymnophthalmate* or 'naked-eyed' *M.*, in which the sense-organs situated around the margin of the body were not protected by a hood. Each member of the order constitutes a single animal, the body consisting of a bell-shaped disc, from the roof of which a single *polypite*, including a mouth, depends.

Med'way, a river of England, rises near Felbridge Park, Surrey, and flows N.E. through Kent, past Maidstone and Rochester, joining the Thames at the Nore. It is about 60 miles in length. The estuary at its mouth is an important harbour. Here are the dockyards of Chatham and Sheerness.

Meeranee (Miami), a village in the province of Scinde, British India, on the bank of the Fulailee branch of the Indus, 6 miles N. from Hydrabad. Here Sir Charles Napier completely defeated the Beluchi army of the Ameers of Scinde, on 17th February 1843. The enemy numbered 22,000, the British only 2800. As the result Hydrabad immediately surrendered, as also did the Ameers, and Scinde was won. Sir Charles Napier did not approve of the war, and his pun on this occasion has become historical—*Pecavi*, 'I have sinned' (Scinde).

Meerane, a town of Saxony, between the Mulde and Pleisse, 10 miles N. of Zwickau by rail. It employs more than 15,000 looms in the manufacture of woollen and mixed fabrics, which are mostly sent to N. America and Japan. In 1847 M. was a mere country town with 7345 inhabitants, but in 1875 it had a pop. of 21,277.

Meer Cossim (Mir Kásim), the last of the Nawabs of Bengal who retained any shadow of independence. In 1760 he was placed on the throne by the British, in substitution of their former creature, his own father-in-law, Meer Jaffier. The price paid was £200,000, and the cession of Midnapur, Burdwan, and Chittagong. He was an energetic man, who set himself to reform the administration, and he seems from the first to have contemplated the expulsion of the British. The rupture was precipitated in 1763 by the exorbitant demands of the Calcutta Council. The Mohammedan sepoys, though trained in the European fashion, were everywhere defeated; and the Nawab, in revenge, murdered several distinguished Hindus, and finally massacred his English prisoners at Patna, to the number of about sixty. M. is said to have died long afterwards in poverty at Delhi.—**Meer Jaffier** (Mir Jafar), the Nawab of Bengal set up by the English after the battle of Plassey. He ruled from 1757 to 1760, when he was dethroned by the English in favour of Meer Cossim, to be again set up in 1765. His death occurred in that year, and is said to have been hastened by the importunity with which the Calcutta Council pressed their claims for pecuniary compensation. He had previously won a reputation as a general, but his subservience to the English caused him to be known as 'Clive's Jackass.' His lineal descendant is still (1877) the titular Nawab of Bengal, with a pension of £150,000 a year.

Meerschaum (Ger. 'sea-foam,' in allusion to its lightness and white colour), a soft compact mineral, a hydrated silicate of magnesia (silica 60·9, magnesia 26·1, and water 12), found in Turkey, Greece, Hungary, Moravia, Spain, France, and Morocco, but principally in Anatolia. It absorbs grease, and when newly excavated makes a lather like soap, hence the Turks use it as a detergent. Its principal use is for making tobacco-pipes and cigar-holders, an industry whose centre is Vienna. After being smoked for some time, a M. pipe assumes a rich amber-brown colour, which is due partly to the absorption of the oil of tobacco, and partly to the dry distillation of liquid fat and wax, in which the pipes are soaked before being sent into the market.

Meerut (Míráth), the chief town of the district and division of the same name in the N.W. Provinces, British India, 25 miles from the right bank of the Ganges, and 35 miles N.E. of Delhi; pop. (1872) 81,386, of whom 29,395 were in the cantonments N. of the town. The history of M. goes back to the Buddhist period, as is proved by an inscribed column of Asoka; and the town was often sacked by the Mohammedans. It contains many old temples and tombs, and one of the largest churches in India. Though a station on the Scinde, Punjab, and Delhi Railway, its trade is small, and there are no manufactures. It is reputed to be very healthy. The cantonments contain a European force of all arms, especially artillery, and form the headquarters of a military division. It was here that the first outbreak took place in the Mutiny of 1857. Some troopers of the 3d Bengal Cavalry had been condemned to long imprisonment for refusal to touch the 'greased cartridge.' On Sunday, May 10th, in the evening, their comrades rose, and with the 20th Infantry and all the bad characters of the town, murdered every European they met, and released the prisoners in the jail. They then made their way safely to Delhi, where the standard of the 'Great Mogul' was forthwith set up.—The *district* of M., which lies in the Doab between the Ganges and Jumna rivers, has an area of 2360 sq. miles; pop. (1872) 1,276,114. It is also watered by the Hindun, and by the Ganges and E. Jumna Canals. The crops are wheat, barley, Indian corn, pulses, sugar-cane, and vegetables; the exports are grain, sugar, saltpetre, and indigo. The chief towns are the rising railway junction of Ghaziabad, Gurhmukteswar on the Ganges, Hapur, and Sardhana.

Meetings, Seditious. Any number of persons may in England assemble for any legal purpose of action or of deliberation. But a meeting with the object of infringing the law, or of disturbing the public peace, is seditious, and an offence at

common law. When such takes place justices are warranted in swearing-in special constables (see **CONSTABLE**), and in adopting the precautions prescribed by 1 and 2 Will. IV. c. 41. Sedition may verge on treason, and come within the scope of 25 Geo. III. as a *levying of war*, and an attempt by intimidation and violence to alter established institutions.

Mega'ceros (Gr. 'large-horned'), or **Irish Elk**, the name given to a large genus of extinct deer, the *M. Hibernicus* or *Cervus Megaceros* of palæontologists. The remains of this genus occur in Pliocene deposits in Ireland, England, and on the Continent; and it is doubtful if the *M.* existed in the Post-tertiary or Recent period. The antlers were large and spreading, sometimes measuring 10 feet from tip to tip. The *M.* was a true deer, allied to the fallow-deer and the reindeer.

Megalich'thys (Gr. 'large fish'), a genus of fossil *Ganoid* fishes found in the Carboniferous formations. They attained a very large size. The tails were 'heterocercal,' or unequally lobed, the teeth large, conical, incurved, and usually smooth, but occasionally ridged or grooved.

Megal'odon (Gr. 'large-toothed'), a genus of fossil *Lamelli-branchiate* mollusca, belonging to the family *Cyprinida* (q. v.). The shells of *M.* were very massive, and had large 'beaks.' They are characteristic fossils of the Devonian or Old Red Sandstone system.

Megalosau'rus (Gr. 'large lizard'), a genus of gigantic fossil *Reptilia*, included in the order *Dinosauria* or *Ornithoscelida*. The remains of *M.* occur in the Oolitic and in the Wild Clay of the Chalk series. The length of the animal has been estimated at 40 or 50 feet. The thigh and shin bones measure about 3 feet; the teeth were numerous, conical, and serrated; and, as was pointed out by Dr. Buckland, they seem to have been renewed by their mode of growth, and to have presented no appearance of wearing action. No hard parts were developed in the outer skin.

Megapod'idæ (Gr. 'large-footed'), a family of *Rasorial* or *Gallinaceous* birds, including the jungle-fowl, *Leipoa*, and the brush turkey or *tallegalla*. The bill is straight and weak, its sides compressed, and its tip arched. The wings are rounded, and the tarsi scaly. The hinder toe is long and rests on the ground, as in the pigeons, and the claws are curved.

Meg'aris, a small district of ancient Hellas, occupying the N. part of the Isthmus of Corinth, and in the N.E. bordering on Attica. Its chief town was Megara, the mother-city of Chalcedon and Byzantium. The Megarians claimed to be the originators of Greek comedy; they had not a good reputation among their Hellenic brethren, and are represented as sensual and dishonest. The courtesans of M., known as the 'Megaric Sphinxes,' were a dangerous race. M. has given name to a school of philosophy, the *Megaric School*, founded by Euclides, a disciple of Socrates. It was famous for the cultivation of dialectics. Pop. of the modern town of Megara, 4023.

Megass or **Cane Trash**, is the refuse of the stalk of the sugar-cane, after the juice is expressed; it is used for fuel, and in paper making.

Megatherium (Gr. 'large beast'), an extinct genus of *Edentate* mammalia, allied to the existing Sloths. In length, the *M.* must have measured 18 or 20 feet, while its height was about 8 feet; its skeleton being massive and elephantine. No incisor or canine teeth were developed, and the molars numbered five above and four below. In shape the molar teeth are quadrangular, and have transverse ridges on their crowns. They appear, further, to have grown during the whole life of the animal, like the tusks of elephants, from permanent pulpa. Collar-bones were developed; the limbs are short and powerful, and the claws large and strong. The pelvis is remarkably solid and compact, and the conformation of the hind-limbs and tail, shows that the *M.* had the power of raising itself from the ground so as to reach the foliage of, or even to uproot trees. The tail is very massive and thick. The remains of the *M.* occur along with those of the mylodon in the recent deposits of S. America. *M. Cuvieri* is a familiar species.

Meglip, a vehicle, generally formed of equal parts of linseed oil and mastic with a little sugar of lead, used by oil painters.

It flows freely from the pencil, and on drying assumes a clear gelatinous consistency.

Me'grim. See HEMICRANIA.

Mehedpore, a town of Central India, in the outlying dominions of the Rajah of Indore, on the right bank of the Seepa, a tributary of the Chumbul, 300 miles S.W. from Agra. In the neighbourhood occurred the battle of M., in December 1817, when the Mahrattas under Holkar, and the Pindarees, were decisively defeated by General Hilslop and Sir John Malcolm. The result was the pacification of Central India.

Meh'emet Ali was born at Kavalla in Macedonia in 1769, and as early as his fourteenth year showed himself possessed of the duplicity and courage necessary for military service in the East. Entering the Turkish army, he was sent to Egypt in 1799 at the head of a corps of Albanians, and assisted the British against the French. Owing to his military ability he rose to be Viceroy of Egypt (1806) through the choice of the Mamelukes (q. v.), whom he exterminated in 1811. For six years he fought against the Wahabis (q. v.) of Arabia, and one of his sons conquered several provinces of Nubia. M. gave the Sultan aid against the Greeks when they declared their independence, but the large fleet despatched by him was destroyed at Navarino in 1827. In 1830 he received from the Porte the government of Cardia for his services. Not satisfied with this, he demanded Syria, which he rapidly conquered, and was only restrained from marching upon Constantinople by the interference of the European powers. In 1839 the Sultan Mohammed waged war on M. in order to regain Syria, and it was not until the European powers had again interfered, until his forces were defeated and Alexandria blockaded, that he abated his pretensions, on the condition that his family should inherit the sovereignty of Egypt. Overcome with years he resigned in favour of his son in 1848, and died at Cairo, August 2, 1849. M. was certainly one of the most remarkable men who in modern years have risen to distinction in the East. Although crafty and cruel, his intellect was singularly keen and strong, and his efforts to graft the civilisation of Europe upon the traditions of the East were followed by a large measure of success. See Mouriez, *Histoire de M., Viceroy d'Egypte* (3 vols. Par. 1855-58).

Mehemet Ali Pasha, a distinguished Turkish general, is the son of a German musician, and was born in Magdeburg, Prussia, in 1829, his real name being Jules Detroit. When aged fifteen he sailed from Hamburg as a cabin boy, but on account of cruel treatment deserted from his ship at Constantinople. Here he secured the favour of Ali Pasha, then Foreign Minister, and subsequently Grand-Vizier, who sent him to the military college. He obtained a lieutenancy in 1853, and was on Omar Pasha's staff during the Crimean War. He served as general officer in the Servian campaign of 1876. In the early summer of 1877 he commanded a division of the army in Montenegro with such success that he obtained the rank of Mushir, and on Abdul Kerim's dismissal succeeded that officer in the supreme command of the Turkish armies in Europe. In September 1877 with the Turkish right he tried to drive in the Russian left on the river Lom, but after some apparent successes, he fell back to his original positions, and was deprived of the chief command in the beginning of October.

Mein'ingen, a town of Germany, capital of the duchy of Sacho-Meiningen, on the Werra, to the S. of the Thuringian Wald, 40 miles N.W. of Coburg by rail. The ducal palace (completed 1682) contains some good pictures and a large collection of engravings. A beautiful 'English garden' or park is attached to the palace. M. is the headquarters of the Credit Mobilier of Central Germany. Pop. (1875) 9521.

Meiss'en, an old town of Saxony, picturesquely situated at the influx of the Triebisch and Meisse into the Elbe, 15 miles N.W. of Dresden by rail. The fine Gothic cathedral (936-1342) stands on the Schlossberg, 160 feet above the town, contains many interesting monuments and brasses, and has a tower (254 feet), with a beautiful open spire. Adjoining it is the Albrechtsburg (1471-83), a large castle built on a precipitous rock, and connected by a bridge of the 13th c. with an old abbey, which was converted into a school in 1543, where Gellert and Lessing received their early education. The celebrated Royal Porcelain Factory (with 600 men), formerly in the Schloss, is now established in a building in the Triebischthal, 1½ miles

from M. The factory was founded in 1710, shortly after Böttiger discovered the art of making 'china.' M. has also iron foundries and engineering works. Pop. (1875) 13,002. The town was founded by Heinrich I. in 928. It was the seat of the Markgrafs of Saxony down to 1090.

Meis'tersinger or **Meistersänger**, the burgess poets, who from the beginning of the 14th c. continued the lyric poetry formed and developed by the Minnesinger (q. v.). Their origin is assigned by tradition to Heinrich Frauenlob of Meissen (1260-1318). It is probable enough that he first founded a school of M. at Mainz, and that the example was afterwards followed elsewhere, especially in the imperial cities. It was chiefly artisans (*Meister*) who formed such corporations, and their art bears throughout a thoroughly mechanical character. On Fridays they met in 'Gesellschaften' or 'Zünfte' to recite their poems and hear those of their guild-brothers. Their chief aim was to follow with nicety a system of external rules for language and metre, called 'Die Tabulatur.' They had regard only to the number and position of the verses and rhymes, and paid no heed to tone or quantity. When a member produced a poem held faultless, he was by the 'Merker' declared a 'Meister.' The M. pushed the mannerism of the later Minnesingers to a ridiculous extreme, and their reading of life is much more narrow and barren than that of the latter. Genius is seldom found among the M., and then chiefly among writers who worked in other fields of poetry, as Heinrich von Mügelin in the 14th c., Muscatblut in the 15th, and in the 16th, the Nürnberg shoemaker, Hans Sachs, who wrote 4275 'Bar' or 'Meisterlieder.' With the 17th c. the M. gradually died away; the last 'Genossenschaft' lingered on at Ulm till 1839. Our knowledge of the M. is mainly derived from Puschmann, *Gründlicher Bericht des deutschen Meistersangs* (Görlitz, 1573; 2d ed. as *Gründlicher Bericht der deutschen Reimen oder Rhythmen*, Frankfurt-am-Oder, 1596), and Wagenseil, *Buch von der M. holdseligen Kunst* (1697).

Meknas, Mekinês, or Meknâsa, a well-built town in Morocco, N.W. Africa, 200 miles N.E. of the town of Morocco, in a fertile valley watered by the Bet, covered with olive groves, and surrounded by well-cultivated hills. M. has a splendid marble palace, the summer residence of the Sultan. It has considerable trade, and manufactures of leather and earthenware. Pop. 15,000 (in summer 55,000).

Mela, Pomponius, a Latin geographer, was born at Tingentera in Spain, and is thought to have flourished in the reign of Claudius (A.D. 41-54). His work *De Situ Orbis* consists of three books, and contains a comprehensive account of the earth's surface as known in his time. He divides the world into two hemispheres—the northern or known, which comprises Europe, Africa, and Asia, and the southern, which is unknown, and lies beyond the impassable torrid zone; and then proceeds to a detailed description of the known world. The best edition is that of Tzschuckius (Leip. 1807).

Melancholia (Gr. *melas*, 'black,' and *cholê*, 'bile') is one of the forms of emotional insanity. Hippocrates, in one of his aphorisms, says: 'If fear or distress continue for a long time, this is a symptom of M. ;' but modern writers, before Esquirol, used the word M. to convey the idea of derangement on some particular point, whether accompanied by gloom or mirth. Esquirol suggested the word *lypmania* in the place of M., but he employs the two words indifferently. The invasion of M. may be sudden, as when it is the immediate consequence of grief, or it may be gradual and the mere exaggeration of natural character, or it may be secondary to other forms of insanity, but the period of incubation is generally prolonged and sufficiently obvious. The more obvious *psychical* symptoms are morbid despondency and gloomy apprehensions of impending evils. The subject of M. is depressed, taciturn, seeks entire solitude, loses his relish for existence, feels unequal to the ordinary duties of life, and as the disorder advances, is constantly anticipating some dire catastrophe. The mind is generally unusually active, every circumstance is exaggerated and unfavourably construed, and the early morning, or after waking from sleep, is the period for increased mental suffering. These symptoms are frequently so intensified as to develop a suicidal impulse, rendering seclusion in an asylum necessary. Attacks of M. are sometimes remittent, the disposition being associated with an acute perception

of, and love for, the ridiculous, as was exemplified in the case of the poet Cowper and the comedian Carlini. In M. the physiognomy is fixed and changeless, but the muscles of the face are in a state of convulsive tension, and express sadness, fear, and terror; the eyes are motionless, and directed either towards the earth or some distant point, and the look is askance, uneasy, and suspicious. Sometimes the arms hang loose at the side, the hands are open, and the muscular system is relaxed; at other times the arms are rigidly flexed, the hands are clasped, and pressed against the chest, or wrung in the agony of despair. In the simple form of M. there is no disorder of the intellect, but only a constant feeling of gloom and sadness, an exaggeration of the affective sentiments. *Nostalgia* (q. v.), or home-sickness, is sometimes a variety of simple M. In complicated M. there is a decided disturbance of the intellectual faculties, and the most frequent forms are the hypochondriacal and the religious. In the former case there is a great variety of delusions, some patients imagining that they suffer from loathsome or deadly diseases, or that their bodies are infested with animals, or possessed of spirits, while others impute to themselves the most atrocious crimes, or imagine that they have been ruined in estate as well as in regard to body and soul. Religious melancholy usually takes the form of a belief that the subject is visited by the Divine displeasure, or is even condemned to everlasting misery. *Revivals* and the fiery denunciations of injudicious preachers are frequently the exciting cause of religious M. The tendency of an attack of M. is to pass into dementia, 'the tomb of human reason.' See *Maladies Mentales*, by Esquirol; *Leçons Orales*, by Guislain; *Annals of Insanity*, by Perfect, and *Psychological Medicine* by Drs. Bucknill and Tuke (London, 1874).

Melanch'thon, Philipp, a great German reformer, was born 16th February 1497, at Bretten, in the Rhenish Palatinate. His proper name was *Schwarzerd* ('black earth'), of which M. is a translation into Greek. He studied at Heidelberg (1509-12) and Tübingen (1512-14), where he joined a society for the cultivation of good Latin, and pursued studies in mathematics, medicine, and jurisprudence. After lecturing on the Greek and Latin authors at Tübingen he accepted the Greek chair at Wittenberg in 1518, his opening discourse being devoted to the reform of the curriculum. The fame of his scholarship attracted hundreds of students to the university, and M., who had been strongly influenced by the writings of Erasmus, threw in his lot with Luther. At Leipsic (June 27, 1519) he took a share in his first combat as a Humanist, exhibiting those qualities of conciliation and tact which have won for him the reputation of being the most reasonable of the Reformers. M.'s first important work, *Loci Communes Rerum Theologicarum*, appeared in 1521, and in it were concentrated the doctrines of the Protestant revolt. About the same time he also helped Luther in the more difficult portions of his translation of the New Testament, and from 1522 till 1534 he busied himself in translating the Old Testament. At Augsburg (1530), at Worms and Ratisbon (1545-46), he distinguished himself in the Protestant service, though at the time he was blamed for his tendency towards compromise. In the midst of the dispute which arose between the Lutherans and Calvinists at the introduction of the Augsburg Interim, he died at Wittenberg, 19th April 1560. Though not sufficiently aggressive to rank as an active Reformer, his work as a scholar and theologian gives him a foremost place in the great movement of the Protestant Reformation. The best edition of his numerous writings, which include classical and biblical commentaries, ethical treatises and dissertations, with a vast academic correspondence, is that of Bretschneider and Bindseil (28 vols. Brunswick and Halle, 1834-60). See Galle, *Versuch einer Charakteristik M.'s. als Theologen* (Halle, 1840); Matthes, *Philipp M., Sein Leben und Wirken, aus den Quellen dargestellt* (Altenb. 1841); Schmidt, *Philipp M.; Leben und ausgewählte Schriften* (Elberf. 1861).

Melane'sia (Gr. *melas*, 'black,' and *nēsos*, 'an island') the collective name given to the islands in the S.W. Pacific, inhabited by tribes belonging to the Papuan race. Though, strictly speaking, Australia comes within this definition, it is usually excluded from M., being treated as a continent, and the term is applied to New Guinea and the chain of islands stretching from it in a S.E. direction as far as the Fiji group. The inhabitants of M. are of a colour approaching black, and have also the crisp, curly hair and thick lips of the negro. They are of quite a distinct

race from the Polynesians, who are of Malay origin and aspect, and speak a single tongue with unimportant variations of dialect. The Melanesians, on the other hand, speak languages of an entirely different character, being harsher and more complex than the Polynesian, and so diverse that it has been suggested that M. might appropriately be called Polyglottia, or the Polyglot Islands. The number of distinct languages spoken in M. has been estimated by the Bishop of Wellington, New Zealand, a competent judge, at 200. The Melanesians are daring voyagers, and in most instances ferocious cannibals. M. forms the see of a missionary bishop of the Church of England, whose headquarters are at Norfolk Island (q. v.). See also FIJI, NEW BRITAIN, NEW CALEDONIA, NEW GUINEA, NEW HEBRIDES, and SOLOMON ISLANDS.

Melanorrhœa (Gr. *melas*, 'black'; *rhœō*, 'I flow') is the name given to a genus of *Anacardiaceæ*, the two species of which it consists supplying, by tapping, a juice that on exposure to the air becomes black, and is used as a varnish for a great variety of purposes. It is very acrid, producing painful swellings if it come in contact with the skin. Both species are natives of the E. Indies, and form great trees upwards of 100 feet high. Its native name is *Theet-tsee*.

Melano'sis. See CANCER.

Melantha'cea, a small natural order of endogens of doubtful limits, but in close alliance with *Liliaceæ*. The plants included in it have in general poisonous properties, many being acrid, purgative, and emetic, and some narcotic. The root-stock of *Veratrum album*, the white hellebore of the Greeks, is an irritant narcotic poison, depending on an alkaloid called Veratrine. It is sometimes given in rheumatism, neuralgia, and when it is necessary to abate the force of the circulation. The most important plant of the order is *Colchicum* (q. v.); see also SABADILLA and HELLEBORE. A few species are cultivated for their handsome blooms.

Melastoma'cea, an extensive natural order of a varied constituency, numbering about 1800 species. They are found mostly in moist, tropical countries, a few in Australia, very few in N. America and Northern India, and none in Europe. All are harmless, and the succulent fruit of some is edible, and from its often imparting a black stain to the mouth, the name of the genus is derived (*melas*, 'black'; *stōma*, 'mouth'). A large number are grown in European hothouses for their showy flowers and other features of interest—e.g., species of *Pteroma* and *Medinilla*.

Mel'bourne, the capital of the colony of Victoria, Australia, is built principally on the N. bank of the river Yarra-Yarra. It was founded in 1835, and was named after Viscount Melbourne, who was premier of Great Britain at the time. Its progress was not rapid till the discovery of gold in 1851, when M. sprang into vigorous life with marvellous suddenness. It is now the most populous city in Australia. The city proper contains but a fourth of the inhabitants of M., who now (1877) number 210,000, and the principal suburbs are under distinct municipal government. The leading business streets of M. are each a mile long and 99 feet wide, well paved, lighted with gas, and lined by shops and warehouses of brick or stone equal to those of the first cities in Great Britain. Land in Collins Street, the most important thoroughfare, has been sold at prices as high as any obtained for land in the City of London. M. possesses many very fine public buildings, mostly of stone, but in some cases still unfinished. The chief are the Town Hall, Post Office, Treasury, Houses of Parliament, Free Library (containing 70,000 vols.), University (with 500 students), Museum, Mint, and new Law Courts. There are also several splendid churches, besides a number of charitable institutions lodged in buildings of the handsomest description. The public parks and gardens are also numerous and extensive. Four daily and fully a dozen weekly and monthly newspapers and magazines are published. M. is the see of a bishop of the Church of England and of an archbishop of the Roman Catholic Church. The climate is good, though marred by hot winds in summer. The mean temperature for midsummer is 66°, and for midwinter 48°, frost being rare. The mean annual rainfall is 27.23 inches. M. is the principal outlet for the trade of Victoria, and is now the most important commercial town in the southern hemisphere (see VICTORIA). Vessels of 600 tons can ascend the Yarra to the heart of the city. Those of

larger size discharge and load at Sandridge or Williamstown, distant respectively 2½ miles and 8 miles by rail from M., and situated on Hobson's Bay, the N. extremity of the inlet of Port Phillip (q. v.).

Melbourne, William Lamb, Viscount, was a son of Sir Peniston Lamb of Brocket Hall, Herts, and was born in London, 15th March 1779. Educated at Cambridge and Glasgow, he was returned to the House of Commons for Leominster in 1805, under the auspices of the Whigs, but before being removed to the upper house in 1828, served in the governments of Canning, Goderich, and the Duke of Wellington. During the great reform debates of 1831 M. pled for a concession to the demands to the people, dreading the consequences of refusal. In July 1834, to the general surprise, he became First Lord of the Treasury and head of the Cabinet, which he held until November, and resumed upon the reassembling of parliament after its dissolution, retaining office until 1841, when he was succeeded by Sir Robert Peel. M. was a wise and patriotic adviser of Queen Victoria in the earlier years of her reign. He died 24th November 1848. M. was a miserable speaker, and never overcame a painful sense of embarrassment with which he was afflicted. 'Everything about him,' wrote Sidney Smith, 'seems to betoken careless desolation; any one would suppose from his manner that he was playing at chuck-farthing with human happiness, that he was always on the heels of fortune, that he would giggle away the great charter. . . But I accuse our minister of honesty and diligence; I deny that he is careless and rude; he is nothing more than a man of good understanding and good principle, disguised in the eternal and somewhat wearisome affectation of a political roud.' His wife, **Lady Caroline Lamb** (born 1785, died 1828), wrote several novels, and was once famous for her admiration of Byron. See *Memoirs of Lord Melbourne*, by W. T. McCullagh (Torrens (Lond. 1877).

Mel'chites ('royalists,' from Syriac *mel'cha*, a king) was the name given in the 5th c. to the orthodox Greek Christians of Egypt, to distinguish them from the Jacobites (q. v.). After the Council of Chalcedon (451) it was applied by the Monophysites (q. v.), whose tenets had been condemned by that council, to the orthodox generally as accepting their creed at the will of the Emperor, who had convened the council.

Mel'combe Regis. See WEYMOUTH.

Melegna'no (formerly *Marignano*), a town of N. Italy, province of Milan, 10 miles S.E. of Milan city, is memorable as the scene of a victory gained by Francis I. of France over the Swiss allies of Milan, 7000 of whom fell in the action, 14th September 1515. A sanguinary conflict took place here between the French and Austrians, 7th June 1859, resulting in the defeat of the latter.

Meléndez Valdez, Juan, a Spanish poet, was born at Ribera del Fresno, Estremadura, March 11, 1754. After studying philosophy at Madrid he proceeded to Salamanca, where he became imbued with a love of English poets, Young and Thomson in particular, and where, after having gone through a course of law, he was appointed Professor of Humanity in 1781. He was made a judge in 1789, and two years later obtained a political appointment at Valladolid. M.'s first literary attempts were dramas, but they obtained little notice. In 1784 he published a volume of lyrics, which at once placed him among the finest song-writers of his country. The exquisite simplicity and subtle pathos of some of his pastorals cannot be surpassed; his anacreontics are likewise very perfect in their way. To these poems M. twice made additions. Having unhappily taken the French side in Spanish politics, he was forced to leave his country, and died in exile at Montpellier, May 24, 1817. The best edition of his works is that in 4 vols. (Madrid, 1832). Some of his pieces have been tolerably translated in Kennedy's *Modern Poets and Poetry of Spain* (Lond. 1852). See Ticknor's *Spanish Literature*, vol. iii.

Mel'fi, a town of Southern Italy, in the province of Potenza, on the N.E. slope of the volcanic Monte Vulture. Its chief buildings are a modern cathedral on the site of an older structure (1155), almost totally destroyed in the earthquake of August 14, 1851; the château of Prince Doria, formerly the castle of Robert Guiscard; a town-hall, bishop's palace, &c. There is a lively trade in wine, oil, cheese, and cattle. Pop. (1874) 11,640.

Meliaceæ, a natural order of about 180 species of trees and shrubs, widely distributed throughout tropical regions. A strong astringent principle pervades the order, at the same time some yield useful oils and balsam, others produce edible fruit, and others furnish valuable timber. *Melia Azadirach*, a native of China, has been transported as an ornamental and useful tree to many countries. In S. Europe it grows freely, presenting when planted in avenues a very handsome effect with its numerous erect spikes of lilac flowers. The fruit consists of pale-blue berries which are strung into rosaries, and have caused the name of 'bead-tree' to be given to the tree. The *Neem-tree* of India (*M. Azadirachta*) yields, by tapping, a kind of toddy, and from the fruit an oil is obtained for domestic and medicinal purposes. Other noteworthy genera are *Ekebergia*, which represents the family at the Cape of Good Hope, and *Carapa* (q. v.).

Mel'ic Grass, a genus of about twenty species, distributed through temperate and subtropical regions, and represented in Britain by *Melica uniflora* and *M. nutans*. Both grow in woods and other shady places. The herbage is relished by cattle, but neither species has been practically brought into use. Others of the genus, as *M. ciliata* (European) and *M. altissima* (Siberian), are recommended for cultivation.

Melicoc'ca, a small American genus of *Sapindaceæ*. The Genip Tree (*M. bijuga*), a native of Guiana and New Granada, is now naturalised in the W. India Islands, where the fruit is much esteemed. In Caraccas it is also used, being roasted as a substitute for chestnuts. The tree itself is remarkable for its large growth and beauty, affording an extensive and grateful shade, while the fragrant flowers attract in swarms bees and humming-birds.

Mel'ilot (*Meililotus*), a genus of annual or biennial fragrant herbs, belonging to the natural order *Leguminosæ*, and numbering about ten species, all of which are natives of warm and temperate regions of the Old World, but have spread far beyond their original limits. In England the common M. (*M. officinalis*) occurs in many parts about the edges of fields, and when intermixed with hay imparts to it both a sweet odour and an agreeable relish, so as to make the plant an acceptable constituent of fodder. The fragrance arises from the presence of Coumarin (q. v.). By adventitious introduction, *M. alba* and *M. arvensis* have also now a recognised place in the British flora. The last is from time to time renewed by being sown with foreign ryegrass and clover seed, and has often been mistaken for *M. officinalis*. *M. carulea* forms an ingredient of the green Swiss cheese, which owes its flavour and colour chiefly to this plant; it is also used to perfume clothes, and affords by distillation a fragrant water.

Melodra'ma, a play of a popular and striking character, usually in five acts, in which eloquence of dialogue and study of human nature are less aimed at than sensational plot and spectacular effect. The word is derived from *melos*, 'a song,' music having been formerly a characteristic of such pieces.

Mel'oë, a genus of *Coleoptera* or beetles belonging to the family *Meloidæ*. M. as the type of the family is a large beetle, of dark-blue colour, seen among grass in May and August. The elytra or wing-covers are short, and the abdomen is large and ovate. The antennæ of the males are twisted and knotted. The eggs are laid on the ground near the nests of humble bees, and in the early spring the young M. are to be found on the bodies of the bees. An intermediate stage, known as that of the *semi-pupa*, is observed to take place in M.'s development, the changes between the larva and pupa stage being very gradually exhibited.

Mel'on (*Cucumis Melo*) is the produce of a herbaceous or climbing annual, originally from the country about the Caspian Sea, and cultivated in Asia and Africa from time immemorial. In the warmer parts of Europe also it has been grown at least from the time of the Romans, and through France and Spain is supposed to have reached England about 1570. It succeeds in the open air as far as 43° N., but is best adapted to countries where the atmosphere is dry, and for necessary moisture the plant has to depend almost entirely on surface irrigation and on dews. The soil on which it is found to thrive best is rather strong fresh loam. The varieties of the

M. are numerous, differing in size, form, and colour. Some are round or oblate, others oblong or oval; the surface of some is smooth; of others ribbed, warted, or netted. The flesh is either white, greenish, salmon-coloured, or red. The whole range under two races—the Persians and the Cantaloups. The former are the most difficult to cultivate, requiring a very high temperature, a dry atmosphere and an extremely humid soil. The Cantaloups (so named from Cantaluppi near Rome) are grown throughout Europe with great success, but are inferior to the Persian. The water *M.* (*C. Citrullus*) is believed to have been earlier introduced into Europe than the foregoing. It is extensively grown in dry, hot countries, forming in Egypt the chief food and drink of the inhabitants for several months in the year. Its abundant refreshing juice is not so rich and sugary as that of the *M.* It sometimes attains a weight of 400 lbs. See *CUCUMBER* and *GOURD*.

Meloria, a rocky islet in the Mediterranean, $4\frac{1}{2}$ miles W. of Leghorn, near which the Genoese defeated the united Imperial and Pisan fleets on the 3d May 1241, and the Genoese fleet almost annihilated that of Pisa on the 6th August 1284.

Melpomene (Gr. 'the songstress,' from *melpō*, *melpomai*, 'I sing'), the Muse (q. v.) of tragedy.

Melrose (Gael. *Maol-ros*, 'the bald headland; ' the old *M.* being situated on a promontory formed by the Tweed), a town of Scotland, in Roxburghshire, picturesquely situated on the S. bank of the Tweed, near the base of the Eildon Hills, 37 miles S.S.E. of Edinburgh by rail. In the market-place is a stone cross bearing date 1642, and a gabled house of 1635 was the place where General Leslie slept before the battle of Philiphaugh. There is a large hydropathic establishment in the vicinity. Pop. (1870) 1405. The crowning glory of *M.* is its beautiful Gothic abbey, admired so widely through Scott's exquisite description of it 'by moonlight' in the *Lay of the Last Minstrel*. Founded by David I. in 1136, to take the place of a lowly monastery that Aidan had planted (635) on the promontory two miles down the river, the building was completed in 1146, occupied by the first Cistercians who entered Scotland, and dedicated to St. Mary. The abbey was destroyed by the English in 1322, but was gradually rebuilt under Robert Bruce and David II. in still greater magnificence. A graceful blending of the Second Pointed style and Flamboyant, it was one of the noblest works of the best age of ecclesiastical architecture. The remains include the main part of the conventual church, 258 by 137½ feet, a hexagonal tower 84 feet high, and traces of the extensive cloisters. The 'east oriel' window of *The Lay*, divided by four mullions, is delicately interlaced by 'foliated tracery.' Only about half the size of York Minster, the whole edifice is rich to profusion in carvings of twining plants and animals, 'grotesque and grim.' It received the heart of Bruce, and contains the tombs of Alexander II., of Douglas of Liddesdale, styled 'the flower of chivalry,' and of the Douglas who fell at Otterburn. The *Chronica de Melros* from 731 to 1275, was published first by Bishop Fell (Oxford, 1684), and then for the Bannatyne Club (Edinb. 1835), while the charters of the later abbey, under the title *Liber S. Marie de Melros*, were issued by Cosmo Innes, at the cost of the Duke of Buccleuch (Edinb. 1837).

Melton Mowbray, a town of England, county of Leicester, in a fertile valley near the confluence of the Eye and Wreak, 115 miles N.W. of London by rail. It is the great meeting-place for the famous 'Melton Hunt,' and has stabling for some 800 horses. Its main industries are the making of Stilton cheese, and the well-known *M.* pork pies (over two tons weekly). There are also tanneries and breweries, and an important weekly market. Pop. (1871) 5011.

Melun (Lat. *Melodunum*, Celt. *Meol-dun*, 'the bald fort'), a town of France, capital of the department Seine-et-Marne, on the Seine, 29 miles E.S.E. of Paris by rail. Its only important buildings are two churches, the Hôtel-de-Ville, rebuilt (1848) in the Renaissance style, with a statue of Jacques Amyot (q. v.), and the remains of a once famous castle. There are manufactures of cotton and woollen fabrics, hats, leather, and farm implements, and a trade in wood, coal, corn, cheese, &c. Pop. (1872) 8403. The residence of the House of Capet, *M.* was captured by the English (1420), and held by them for fifteen years.

Melville, an island belonging to British America, and lying in the Arctic seas between the parallels 74° and 77° N. and the meridians 105° and 117° W. Fitzwilliam and Kellet Straits separate it from Prince Patrick Island on the W.; Banks Strait and M. Sound from Banks Island and Prince Albert Land on the S.; and Byam Martin Strait from Bathurst Island on the E. It was discovered in 1819 by Parry, who wintered here in hopes of finding an open passage to the W. *M. Peninsula* lies to the N.W. of the entrance to Hudson Bay, and is connected with the mainland by Rae Isthmus.

Melville, Andrew, an illustrious Scottish reformer, was born at Baldov, near Montrose, August 1, 1545, educated at Montrose grammar-school, St. Andrews, and Paris, was Regent (1566-69) in the College of St. Marcéon, Poitiers, thence went to Geneva, where Beza got him a chair of Humanity, and returned to Scotland in 1574. In the same year he made his first appearance in the Assembly, and owing to his zeal and scholarship became a leader of the Presbyterian Church. Appointed Principal of Glasgow University, he wrote, while holding that office, his *Carmen Mosis* (a Latin paraphrase of the 32d chapter of Deuteronomy), which is as fine as anything in Buchanan. But he had a consuming passion for ecclesiastical politics, and even sacred literature was a pastime rather than a labour. 'He was,' says Mr. Burton, 'the type of a class who to as much of the fierce fanaticism of the Huguenots as the Scotch character could receive, added the stern, classical republicanism of Buchanan.' In 1580 *M.* was appointed to the Principalship of St. Mary's College, St. Andrews; in 1581 was completed the *Second Book of Discipline*, which, based upon the Huguenot code, was put into shape by *M.* In the face of the Government of 1583, which had determined to reduce the freedom of speech claimed by the clergy, *M.*, when cited before the King and Council, argued that 'they presume over boldly in a constituted state of a Christian Kirk—the kingdom of Jesus Christ—to take upon them to judge the doctrine and control the ambassadors and messengers of a King and Council greater than they, and far above them.' He was ordered to the castle of Blackness, but escaped to Newcastle, where he established a congregation with a staff of elders and deacons, who applied the system of discipline with great severity. In 1596 *M.*, having meanwhile been reinstated in his office at St. Andrews, forced himself into the presence of the King, at a meeting of the Estates in Falkland, and denounced the Popish lords whose case they were considering. The King forced him to depart; but in the following September, at an Assembly at Cupar, *M.* formed one of a deputation which discussed the same subject against the royal will. His Majesty was told that he was 'God's silly vassal,' and that in Christ's kingdom, the Kirk, he was neither king, nor head, nor lord, but a member. In 1605, though prohibited by royal proclamation, *M.* called a General Assembly at Aberdeen. He was summoned to the English court to justify himself, and, when there, having ridiculed the decorations of the communion-table, he was handed over to the keeping of the Dean of St. Paul's, and afterwards to the Tower, where he remained for several years. In 1611 he was released, on condition that he lived abroad, and died a Professor in the Huguenot University of Sedan in 1622. Mr. Burton says—'Had it been his lot to lead a haughty ecclesiastical hierarchy, striving to subdue and control secular principalities and powers, he would have made another Hildebrand or A'Becket.' This is true so far as it goes; it points out clearly enough the peril that would have threatened secular liberty had *M.*'s principles triumphed, but the fearless heroism of his character stamps him with a greatness and a dignity that can hardly be surpassed. It has been stated that *M.* was a scholar and a poet as well as an ecclesiastical politician. In the *Delicia Poetarum Scotorum* are pieces of his which once were famous and deserve to be remembered. See *M'Crie's Life of A. M.* (2 vols. 1819; 2d ed. 1823; new ed. 1856); Burton's *History of Scotland*, vols. iv., v.—His nephew James *M.*, born at Montrose, 25th July 1556, was an able coadjutor of Andrew in his strife on behalf of Presbyterianism. Milder and more courteous than his great kinsman, he was nevertheless firm and decided in his opinions. In 1606 he was summoned to London for protesting against Episcopacy, was refused permission to return to Scotland, and died at Berwick-on-Tweed, 13th January 1614. He wrote several works

both in prose and verse, but his *Diary* (printed for the Bannatyne Club) is the only one possessing a permanent interest. See *Wodrow's Life of James Melville*.

Melville, Herman, an American author, born in New York, August 1, 1819, took to the sea at eighteen years of age, and for a few years off and on was before the mast. In 1846 he published *Typee*, and in 1847 *Moo*, graphic and popular accounts of his adventures with the natives of the Polynesian Islands, by whom he had been taken prisoner in 1842. He has also written *Mardi*, a philosophical romance (1849), *White Jacket* (1850), *Toby Dick* (1851), *Israel Potter* (1854), *The Confidence Man* (1857), *Battle Pieces* (a volume of poems, 1866), &c.

Melville, Sir James, was born at Halhill, Fifeshire, in 1530, and was page to Queen Mary of Scotland. In 1564 he was sent to the English court with friendly messages to Elizabeth concerning the approaching marriage with Darnley. Two years later he acted as interim secretary to the Scotch Queen, and was an unwilling confidant of Darnley, who remarked to him about the murderers of Rizzio, 'As they have brewed so let them drink.' The same year he was sent to announce the birth of James VI. of Scotland to the court of England. In 1567 he remonstrated with Mary in connection with her marriage with Bothwell, and received the answer that 'matters were not that far agaitwart.' He was afterwards carried with her a captive to Dunbar, and negotiated the surrender of Edinburgh Castle. M. was asked to undertake a mission to Denmark (1595) in connection with the proposed marriage of James VI. to the younger daughter of the King, but he escaped from the duty. 'He was,' says Burton, 'a man of a character and temper rare for that age—very pacific, yet no coward; a dealer with all parties, yet never, as it would seem, suspected of selling one party to another.' He received the last instructions of Queen Mary on the scaffold. His *Memoirs of Affairs of State*, one of the most valuable of historical references, was printed for the Bannatyne Club in 1827. He died 1st November 1607. See Burton's *History of Scotland*, vols. iv., v.

Melville, Viscount. See DUNDAS.

Membrana Pupillaris, a term applied to the delicate membrane closing the pupil of the eye in the foetus during the early months of development. The M. P. itself forms the front portion of a membrane, richly supplied with blood-vessels, which encloses the lens of the eye, and which is known as the *membrana capsulo-pupillaris*. The M. P. disappears about the seventh month of intra-uterine life.

Membrane, a general term applied in anatomy and physiology to indicate any soft texture made up of tissues. We thus speak of the 'membranes of the brain,' of mucous M., or serous M., while the membranes within which the embryo is contained *in utero* are named the 'foetal M.' The term *Meninges* is applied to the collective brain membranes.

Me'mel, the most northerly town of E. Prussia at the mouth of the Dange, and on the mainland, at the N. entrance to the Kurisches Haff, 9 miles W. of the Russian frontier, and 53 N.N.W. of Tilsit. It is strongly fortified, and has a large, safe harbour, extensive manufactures of linens, cordage, sail-cloth, bone-black, chemicals, &c., large iron-foundries, distilleries, breweries, and saw-mills, and an important trade in timber, grain, hemp, flax, linseed, amber, coal, calf-skins, petroleum, and salt herrings. In 1875 (an exceedingly bad year) the total imports amounted to £1,099,450, and the exports to £1,174,530; in 1873 the value of imports and exports was £2,990,775. The value of timber exported (1875) was £735,165, of flax £125,225, of grain £46,000, and of linseed £77,000. At the beginning of 1876 there belonged to the port 85 sea-going vessels of 32,020 tons, besides 10 steamers. A railway connecting M. with Tilsit was opened 15th October 1875, and a branch to the Russian railway between Mitau and Libau, which is contemplated, will greatly extend its Russian trade. Pop. (1875) 19,801. M. was founded by the Livonian Order of Knights in 1253.

Mem'ling, Hans, one of the greatest painters of the old Flemish school, was born about 1435. Much that was formerly related of him has been entirely discredited, and now almost all we know is that he led a roving life, fought for Charles the Bold at Granson and Morat (1476), was an inmate of St. John's Hospital, Bruges, for which he painted five of his finest works, and died about 1495. His famous reliquary, the *Chasse de Ste. Ursule* (1487), in St. John's Hospital, is an admirable specimen of his

rare colouring and exquisite finish and fidelity. Other works by M. are at Danzig, Munich, Turin, and Lübeck.

Memm'ingen, a town of Bavaria, S. Germany, on the Aach, 45 miles S.W. of Munich by rail, has a fine Rathhaus, dating from 1526, and three churches, of which St. Martin's contains 67 choir-stalls with rich Gothic carving. The industries are hop-growing, bell-founding, dyeing, and the manufacture of starch, gunpowder, hardware, and linen and woollen yarn. Pop. (1875) 7770.

Mem'non, in Homer a son of Eos, appears in post-Homeric legends as an Æthiopian prince, son of Tithonus, who came to the relief of Priam, and, after having slain Antilochus, was laid low by Achilles. From his ashes Zeus produced a flock of birds called 'Memnones' or 'Memnonides,' which fought one another on his grave, and every year renewed the struggle. Great buildings, as well in Asia as in Egypt, were attributed to M., after whom they were called 'Memnonia.' The two statues of M., still extant, originally stood before the temple of Amenophis III., at Thebes, in Egypt. They rose 70 feet above the floor of the temple, and were composed of a silicious conglomerate so hard and brittle that the change of temperature on the rising of the sun caused little pieces to break off. The sound thus produced gave occasion to the legend of the 'sounding statues' of M.

Mem'ory is properly only the faculty of mental retention; it preserves knowledge within the mind, but without the sphere of consciousness. But it is generally looked upon as reproductive also—and that in two ways. If the laws of association be allowed to work without the intervention of will, as in reverie, M. is then spontaneous suggestion; but if will be brought to bear on the mind's acts, it is then recollection. To the former of these processes alone ancient philosophy gave the name of M. Hamilton terms the one the Conservative Faculty, the other the Reproductive Faculty.

Diseases of M.—M., or the power of reproducing mental impressions, may be naturally weak, or become gradually impaired by age. When any change from the normal condition takes place either in the form of exaltation or blunting, it is indicative of disturbance in some part of the cerebro-spinal structure, the result of external violence, or of various physical conditions, such as fevers, intemperance, congestion, organic disease of the brain or of its membranes, &c., &c. The particular portion of the brain implicated when memory is impaired has not as yet been precisely defined; but the deviations appear to depend upon changes generally of an apoplectic nature in the anterior lobes of the brain. It occasionally happens, though but rarely, that memory is the only faculty impaired, and, when such is the case, the impairment is generally but the precursor of more extensive cerebro-mental lesions.

Mem'phis (*Men-nefer*, 'good port,' in the hieroglyphics), the ancient capital of the kingdom of Upper and Lower Egypt, stood on the left bank of the Nile, on the site of the modern Mitranieh, 10 miles S. of Cairo. Its foundation is ascribed by Herodotus to Menes, whose date is variously fixed at 4455 and 2690 B.C.; and the kings of the later dynasties vied in its adornment. Within a circuit of 15 miles it contained the temples of Isis, Apis, Serapis, Phre, and greatest of all, of Ptah—the *Ilephasteum* of the Greek geographers—with a colossal statue of Sesostrius (Rameses III.), 45 feet high, and a recumbent figure of Amosis, 73 feet long. The Necropolis, with the Pyramids (q. v.), and the dyke of Menes, built to exclude the inundations of the Nile, should also be noticed. The ruin of M. began with the invasion of Cambyses (525 B.C.), was hastened by the founding of Alexandria (332), and completed by the Saracen conquest in the 7th c. A.D. See EGYPT; and Lepsius, *Denkmäler aus Aegypten* (12 vols. Berl. 1849-59).

Memphis, a city of Tennessee, U.S., on the E. bank of the Mississippi, which affords communication in all seasons with New Orleans, distant 380 miles S. by rail. It has thirty-five churches, sixty-seven free public, and thirty-two other schools, a cotton exchange, five stone-paved wharves, nearly two miles long, three daily and seven weekly newspapers. Cotton, gathered from the basins of the Mississippi, White, Arkansas, St. Francis, and other rivers, is the great article of commerce. In 1874 the total value of imports was \$60,847,389, including 426,676 bales of cotton, valued at \$34,006,000. During the same year there arrived 2059 steamers, and departed 2075, averaging 2000 tons each. The

amount of taxable property for 1874 was \$32,500,000. Pop. (1871) 40,226. M. was incorporated in 1827. An engagement took place on the river (6th June 1862) by which the Federals captured M., which was regained by General Forrest's cavalry in August 1864.

Mena'do, a Dutch residence in the extreme N. of Celebes, has an area of 1267 sq. miles, and a pop. of 228,051. The country, broken by volcanic action into highland masses, is well adapted for the extensive cultivation of coffee and rice. In 1870 the total value of the exports amounted to 1,250,370 gulden. The town of M., situated on a bay on the N.W. of the island peninsula, has a pop. of 6000.

Menage', Gilles, an ill-tempered wit and scholar, was born at Angers, August 15th, 1613. After practising at the bar he entered the church, and became one of the lively, accomplished, graceless abbés, forming so unique a class in France, then ornamenting society better than religion. He died July 23, 1692. Of his numerous works we need only mention the *Dictionnaire Étymologique* (1694). See notice of his life prefixed to *Menagiana*, a collection of his good sayings (1715).

Men'ai Strait, a channel 13 miles long and from 250 yards to two miles wide, separating the island of Anglesea from Caernarvonshire, Wales. It is crossed by the M. Suspension Bridge, a fine work constructed by Telford, at the cost of Government, in the route of the London and Holyhead mail-coach road, 1818-25, and by the Britannia Tubular Bridge (q. v.), erected 1846-60. At the entrance to the channel the tide is usually about 12 feet, and sometimes rises to 30, but for expedition the route is often chosen by vessels under 100 tons. The name 'Menai' probably contains the Celtic root *man*, 'a district.'

Menand'ar, the greatest poet of the Athenian New Comedy, was born at Athens 342 B.C. The comic poet Alexis was his uncle, and the philosophers Theophrastus (q. v.) and Epicurus (q. v.) were his intimate friends. Of his personal life little is known, except that his beauty and refinement of manners were remarkable, that his friendship with Demetrius Phalereus nearly cost him his life in 307 B.C., and that he was drowned in the harbour of Peiræus in 290. When the chorus of the Old Comedy was out of date, and the license of its personal attacks was repressed by law, M. created a drama of manners, character, and plot, the prototype of modern comedy. The preference given to his rival Philemon was small earnest to him of the reputation which his works afterwards enjoyed, and which is attested by their holding the stage till the time of Plutarch, and by the fact that almost all the Roman comedy is founded on them. Of more than 100 plays there are now extant only the names, and certain fragments full of gnomic wisdom, as, 'whom the gods love die young.' Of these the best edition is Meineke's *Menandri et Philemonis Reliquiæ* (Berl. 1823), reprinted in his *Fragmenta Comicorum Græcorum*, vol. iv. (1841). See Guizot, *Menandre une Étude Historique* (Par. 1855).—**M.** of Laodicea, a Greek rhetorician of the 2d and 3d centuries A.D., of whose writings are extant a treatise *De Incomitis* or *De Genere Demonstrativo* (Heeren, Gött. 1785; Walz, *Rhetores Græci*, vol. ix., 1836).

Men'chikoff, Alexander Danilovitch, Prince, a Russian statesman and general, was born in humble life at Moscow, November 27, 1672. Introduced to the service of Peter the Great by General Lefort, on the death of that officer in 1699 he became the favourite companion and adviser of the Czar. He gained the victory of Kalisch over the Swedes in 1706, greatly contributed to that of Poltowa in 1709, took Riga in 1710, Courland in 1711, and Stettin in 1713, and was appointed in succession field-marshal, baron, and prince of the empire. He wielded great power during the reign of Catherine I. (1725-27), but shortly after the accession of Peter II. was banished to Siberia, where he died, October 1729.—**Prince Alexander Sergejevitch M.**, great-grandson of the preceding, a Russian admiral and general, born in 1789, accompanied the Emperor Alexander I. in the campaigns 1812-14, when he attained the rank of general. In the war with Turkey, 1828-29, he distinguished himself by the capture of Anapa, but was wounded at Varna. On his recovery he devoted himself to the improvement of the Russian navy, becoming Minister of Marine in 1836. In 1853 he was sent as ambassador-extraordinary to Constantinople. His somewhat intemperate conduct contributed to the outbreak of war, upon which he received the chief command both of the Russian naval and military forces. Although he

lost every pitched battle, he showed great tenacity and determination in his prolonged defence of Sebastopol. He was commander at Cronstadt, 1855-56. M. died at St. Petersburg, May 2, 1869.

Men'cius. See MENG-TSE.

Men'delssohn, Moses, born at Dessau, 6th September, 1729, was the son of a Jewish schoolmaster. He had a good Jewish education, studying under the Rabbi Frankel the works of Maimonides, especially the *Moreh Nebuchim* (Arab. *Delalatti Al-heirim*; Lat. *Ductor Perplexorum*, 'Guide of the Perplexed'), the great source of natural interpretation of Scripture among the Jews. Struggling against poverty and an enfeebled constitution, M., now at Berlin, was introduced to mathematics by Israel Moses, and to Latin by Kisch, a physician of Prag. He read Locke's *Essay*, and a friend named Gompertz gave him the works of Leibnitz and Wolf. In 1754, M., now a partner in a silk business, made the friendship of Lessing; they wrote together *Pope ein Metaphysiker*. His first important metaphysical work was the *Briefe über die Empfindungen* (1775), or 'Letters on the Sensations,' in which he specially analyses the Ideas of the Beautiful. M. belonged to the unscientific school of Wolf. He now became the friend of Abbt, Sulzer, and the librarian Nicolai, and assisted them and Lessing in several literary periodicals, in which they sought to stir the dormant faculties of Germany. In 1767, appeared his *Phædo*, in which he infers the immortality of the soul from the indefinite perfectibility of human nature, its infinite duties, and great desire to live hereafter. His book *Jerusalem* (1783) deals with the question of toleration, and had its effect in preparing the way for the emancipation of the Jews, that his other works had in stimulating the reformation of their religion. The *Morgenstunden* (1785), an exposition of the grounds for believing in the existence of God, and containing a refutation of Spinozism (with which Jacobi had charged his friend Lessing), was interrupted by his death at Berlin, 4th January 1786. One of his daughters became a Christian, and married Friedrich Schlegel. M.'s works were published by his grandson, G. B. Mendelssohn (7 vols. Leips. 1843-45). They include translations of the Pentateuch and Psalms into German. Mirabeau did much to make M.'s works known in France. See Kayserling, *M. M., sein Leben und seine Werke* (Leips. 1862).

Mendelssohn-Bartholdy, Felix, a great German composer, grandson of the preceding, was born at Hamburg, February 3, 1809. M.'s home from 1812 was Berlin, where he was instructed in composition by Zelter and in pianoforte by Berger, and played in public at the age of eight. He could compose skilfully in 1821, received additional piano lessons from Moscheles in 1824, and in the next year devoted himself entirely to music, though of independent fortune. His first great work was the overture to *Sommernachts Traum* (1826); his next, the overture entitled *Meeres-stille und Glückliche Fahrt* (1828). A comic opera, *Die Hochzeit des Gamacho* (Berl. 1827) was a failure. M.'s introduction to the public properly dates from his visit to England in 1829, where the first-named work excited the warmest interest. The overtures, *Isles of Fingal* and *The Hebrides*, and the wonderfully picturesque Scotch symphony, were the fruits of a Highland tour in the same year. In Italy (1830-31) he wrote the *Reformations Symphonie*, and the first *Walpurgis Nacht*. On a London visit in 1832 he played his noble *G-Minor Concerto* (May 28th). On October 4, 1835, he began his great and useful career as Director of the Gewandhaus Concerts at Leipsic, and what may be called his period of travel came to an end. M. directed all his energy to bringing out the finest music before the public, industriously composing at the same time. On May 22, 1836, his oratorio *Paulus* (Paul), was first performed (Düsseldorf), and on September 20th it was given at the Birmingham Festival, M. himself conducting. To 1837 belong the *D-Minor Concerto* and the *42d Psalm*; to '38 three violin quartets, and the *Serenade and Allegro Giocoso*; to '39 the *Pianoforte Trio in D-Minor*; to '40, the *Lobgesang* ('Hymn of Praise'). In 1841 M. was made Ph. Doc. by the Leipsic University, and *Kapellmeister* to the King of Saxony, while the King of Prussia gave him the Order of Merit, and the post of general musical director at Berlin. The year 1843 (April 3) saw the establishment of the Leipsic Conservatorium. M. proposed the scheme, worked hard for it, and was one of the first teachers. In the same year he completed the music for the *Sommernachts Traum*, and composed *Athalie*. In 1844 he was

again in London performing and conducting; in '45 he resigned his Berlin post and began composing *Elias* (Elijah). This oratorio, his grandest choral work, only second in popularity to the *Messiah*, he conducted at the Birmingham Festival, August 25, 1846. Excessive exertion was wearing out his nervous constitution, but the sudden death of his sister Fanny (May 14, 1847) gave him a shock from which he never recovered. He went to Switzerland for change, but returning to Leipsic became much worse, and died there, November 4, 1847. M. was a noble successor of the greatest masters, and, unlike many of them, he was enthusiastically loved and admired in his lifetime, not less for his pure and genial character than for his splendid attainments. Full of tenderness, passion, and sympathy, his compositions glow with the divine ardour of genius. Though a brilliant improvisatore, M. was an ardent student, and possessed, moreover, a range of liberal culture far beyond the average of great composers. Besides the works named, he wrote much for the piano, and many songs; his *Lieder ohne Worte* ('Songs without Words') are widely known. Much also remained unfinished—e.g., an opera *Lorelei*, and the oratorio *Christus*. See his *Reisebriefen* ('Letters from Italy,' 1861; Eng. trans. Lond. 1863); Keissmann, *Felix M., sein Leben und seine Werke* (Berl. 1866); E. Devrient, *Erinnerungen an F. M. B.* (Eng. trans. 1869); Hiller, *Briefe und Erinnerungen* (Eng. trans. 1874); and Lampadius, *Leben des M. B.* (Eng. trans. 1877).

Men'dicant Orders of monks were certain orders which took their rise in the 13th c. The old orders had so given themselves up to sloth, luxury, and vice, that they had become a scandal to the Church in the eyes of the people. It was at this time that Francis of Assisi founded the first M. O., by drawing around him a society whose members came under a vow of absolute poverty, extreme asceticism, and constant efforts for the conversion of sinners, in the strictest obedience to the Apostolic See. Although the formation of any new order had been forbidden by the pope (1215), the suitability of this new order to the wants of the Church was at once recognised, and it was established by Pope Honorius III. 1223. (See FRANCISCANS.) The order of Dominicans (q. v.) was founded at the same time, and these two were followed by the Carmelites (q. v.) and the Augustine-Eremites. (See AUGUSTINES.) The partiality shown towards the new orders by the popes, whose influence they had greatly increased, and the reverence felt by the people for those so distinguished by sanctity from the monks of the old orders, increased the number of orders and members to such an extent that Pope Gregory X. in the Council of Lyon (1272) limited them to the four orders mentioned above. See FRIARS.

Men'dip Hills, in Somersetshire, England, extend inland from the Bristol Channel for about 30 miles in a S.E. direction parallel to the river Axe, and attain their greatest height of 1100 feet in Black Down. They consist mainly of limestone and Old Red Sandstone, were once covered by a forest that belonged to the crown, and are rich in lead, iron, calamine, manganese, red ochre, and other minerals which have been mined from the most remote times. In 1862 Professor Ansted discovered near Wells a mass of the refuse of old mines containing some 600,000 tons of metal, worth half a million sterling.

Mendo'za, the capital of a province of the same name, in the Argentine Republic, at the E. base of the Andes, at a height of 2891 feet above the sea, and 115 miles E.N.E. of Santiago. It was a thriving town with 15,000 inhabitants in 1861, when it was totally destroyed by an earthquake. It was, however, rebuilt on the old site, and has now a pop. of 6000.

Mendoza, Don Diego Hurtado, a Spanish author and statesman, was born of a noble family at Granada in 1503. After leaving the university of Salamanca he joined the Spanish army in Italy, where he continued his studies. He became ambassador at Venice in 1538, commander at Siena in 1547, and shortly afterwards ambassador to Rome. He was dismissed from the court by Philip II. in 1567. He died April 1575. His best works are his *Lazarillo de Tormes* (Antw. 1554, Par. 1627, Gotha, 1810), an admirable satirical romance, the earliest of the *Gil Blas* class of novels, in which Spanish literature is so rich, and his *Guerra contra Los Moriscos*, an eloquent history, so impartial and outspoken that its complete publication was prohibited till 1776. His poems were published (the only edition) in 1610. He gathered a magnificent collection of MSS., now in the Escorial.

See Ticknor's *History of Spanish Literature* (vol. i.).—**Juan Gonzales de M.**, born at Toledo about 1540, served for some years in the Spanish army, afterwards entered the order of St. Augustine, and was sent to China in 1580 by Philip II. to gather information regarding the country. On his return he published *Historia de las Cosas mas notables Ritos y Costumbres del Gran Reyno de la China* (Madr. 1586). It was translated into English in 1588 (reprinted by the Hakluyt Society, 2 vols. 1853-54), and is a work that still possesses both interest and value. M. ultimately became Vicar-apostolic of Mexico (1607), and Bishop of Popayan, New Granada, where he died in 1617.

Mendun-men, the name of the present king of Independent Burmah. Previously known as the Prince of Mendun, he gained the throne in February 1853 by leading a successful revolution against Pagan-men, whose cruelties had rendered him odious. Among the early acts of the new king was to found the new capital of Mandalay. Though retaining all commerce as a monopoly in his own hands, he has on the whole shown a desire to maintain smooth relations with his British neighbours. M. was recrowned at Mandalay in 1874. He is reported to be a zealous Buddhist, but kindly disposed to European residents. See Dr. Anderson's *Mandalay and Momein* (Lond. 1876).

Menela'us, King of Lacedaemon, one of the bravest of Homer's heroes, was the younger brother of Agamemnon (q. v.) and husband of Helen (q. v.). After the fall of Troy, to which, under the protection of Hera and Athena, M. greatly contributed, he and Helen wandered for eight years in the eastern parts of the Mediterranean, at length reaching Sparta on the very day when Orestes buried Clytemnestra and Ægisthus. After this they lived happily together at Sparta, in a palace glorious as the sun.

Mengs, Anton Rafael, son of an artist, who trained him with excessive severity, was born, 12th March 1728, at Aussig, in Bohemia, went to Italy (1741), remained there for four years, and on his return to Dresden his pictures in crayon so pleased the king that he was nominated court painter. Returning to Rome he produced the 'Holy Family,' and married the peasant-girl who sat to him as a model. In 1749 he was commissioned to paint an altar-piece for a new Catholic church at Dresden; in 1754 he took the direction of the new school of painting established at the Vatican. After achieving fame with his 'Cleopatra,' 'Magdalene,' and others, he went to Spain in the suite of Charles VII. (1761). The 'Ascension' and 'Meeting of the Gods' are fruits of his labour at that time. After a residence in Italy he returned to Spain (1775), and in two years executed the 'Triumph of Trajan' and the 'Temple of Glory.' He died at Rome, 29th June 1779. M. conscientiously strove to reproduce the characteristic qualities of the greatest masters, and in a large measure he succeeded. It is agreed, however, that though his taste is good and his technical skill irrefragable, he is at best but a successful imitator. M. left writings on art in German, Spanish, and Italian.

Meng-tse, or Meng-ko (Lat. *Mencius*), a Chinese philosopher, was born at Tseou, in the modern province of Shan-tung, about 398 B.C. After receiving a careful education from his mother, M. became a pupil of Tse-tse, the grandson and disciple of Confucius, and then travelled from court to court, inculcating the doctrines of *hiao*, or filial piety, under which head he included all the relations of social life. Meeting, however, with but small success, he passed the last twenty years of his life in retirement, and died about 314 B.C. M.'s conversations with princes and others form the so-called *Book of M.*, the fourth and most considerable portion of the *Sse-chou* of Confucius (q. v.), and have been translated into Latin by P. Noel (Prague, 1711) and Stanislas Julien (2 vols. Par. 1824, with text), into English by Collier (Malacca, 1828), into French by Pauthier (Par. 1831), and into German by Ernst Faber (Elberfeld, 1877). See Dr. Legge's *Life and Works of Mencius* (Lond. 1873).

Menin, a town of Belgium, province of W. Flanders, on the Lys, 30 miles S.W. of Bruges by rail, has some manufactures of lace, tobacco, beer, &c. Pop. (1874) 10,396.

Meningitis (Gr. *mêninx*, 'a membrane') is the term employed in medicine to designate inflammation of the *arachnoid* and *pia mater*, the investing membranes of the brain. The earliest symptoms are acute pain in the head, intolerance of light and sound, sleeplessness and delirium. The countenance

is flushed, the conjunctivæ red, the eyes suffused, and the pulse quick. As the disease advances, there are frequent spasmodic twitches or convulsions, and eventually coma and complete relaxation of the limbs. *M.* may be simple and idiopathic, or it may be the result of some zymotic or constitutional disease, such as the specific fevers, or the rheumatic, strumous, or syphilitic cachexia. It is sometimes connected with teething. *M.* may be caused by exposure to the heat of the sun, by great mental work or anxiety, but most frequently by the excessive use of alcoholic liquors. *M.*, in the child, is generally *tubercular*; in the young, the result of specific fevers, such as scarlatina and measles. *Treatment*:—Depletion and active cathartics are useful, when not otherwise contra-indicated. The hot bath, and cold applications to the head, such as ice or evaporating lotions, are generally serviceable, and counter-irritants to the nape of the neck may be often of advantage. The patient should be kept on low diet, and excitement of every kind should be avoided.

Menippus, a cynic philosopher, and follower of Diogenes, was born a slave at Gadara, in Coele-Syria, and flourished about B.C. 60. He is said to have committed suicide on being cheated out of a large fortune which he had collected by usury. The satirical works which contained his teaching are lost, though some fragments remain of Varro's *Satura Menippeæ*, written in imitation of them.

Menispermaceæ, a natural order of exogens, chiefly climbing shrubs of tropical countries. They possess a bitter principle—some being tonic, others narcotic, and even poisonous. Some are used for the cure of snake bites. The estimated number of species is about 350, and the genera of greatest economic value are noticed under **CALUMBA**, **CISSAMPELOS**, and **COCCULUS**.

Menn'o, or **Meno Sim'ons**, founder of the sect of the Mennonites, was born in 1496 at Wittmarum, in Friesland, and was a Catholic priest first at Pingjum (from 1524), afterwards at his native place. In 1536 he joined the Anabaptists, of whose tenets he became a teacher at Groningen. After the execution of Jan of Leyden (q. v.) and the other leaders of the Anabaptists (q. v.), *M.* set himself to the work of reorganisation, for this purpose travelling through Holland and N. Germany, till persecution drove him to Wismar, where he held the *Colloquium Vismariense*, preserved by Johann Wigand in his work *De Anabaptismo* (Leipa, 1582). He finally found a retreat in Holstein, where he died, 13th January 1561, at Oldes'oho. *M.* was a good man, whose temperate example did much to remove the fanatical violence of his followers. Before his death they had split into *Die Feinen*, an extreme, and *Die Groben*, a moderate party, the latter being also called 'Flemings,' 'Flandrians,' or 'Waterlanders.' The milder section again divided into the Armenian 'Galenists' and the Calvinistic 'Apostolists,' but these were united in 1801. In Germany, from which in 1783 many Mennonites removed to the banks of the Dnieper, they now number 14,000, and in Holland there are 120 congregations. In 1870 the Russian Mennonites numbered 40,000, but of these, owing to the imposition of the conscription in 1871, large numbers have emigrated to the United States, where there are 500 Mennonite churches, with 250 pastors, and 60,000 members, and also to Canada, where they were welcomed in September 1877 by Lord Dufferin, the Governor-General, in a speech distinguished by admirable sense, and a noble and winning catholicity of sentiment.

Menop'oma, or **Men'opome** (*Protonopsis horrida*), a genus of *Amphibian* vertebrates, allied to the newt and salamander (*Urodela*), and also known as the 'hell bender,' 'mud devil,' &c. This creature inhabits the Ohio and Alleghany rivers, and attains a length of 2 feet. It is voracious, has numerous small teeth, and devours large quantities of fishes. The colour is a bluish-grey, variegated with darker spots. Its repulsive appearance has procured for it the evil but unfounded reputation of being venomous.

Menstruation, otherwise known as the menses and catamenia, is the name applied to the sanguineous discharge which proceeds from the genital organs of the human female at monthly intervals. *M.* corresponds with the period of 'heat' and 'rutting' in lower animals, and marks the period of reproductive activity. *M.* may be regarded as being the sign of the deeper process of *ovulation*, i.e., the rupture of a Graafian vesicle and

the discharge of the *ovum* or egg, which, when duly fertilised, is capable of developing into an embryo. The first occurrence of *M.* in temperate climates takes place from the 14th to the 16th year. Its advent happens much earlier in warm climates, and is delayed in colder latitudes. It ceases during pregnancy and generally during *lactation* or nursing, although it may supervene during the latter period, and has been known to persist during the whole period of utero-gestation. The menstrual period extends over three or four days, but in this respect, as well as in respect of the interval that elapses between the periods, *M.* exhibits great variations. The function usually ceases between the 45th and 50th years of life, but cases of protracted *M.* are by no means rare. The menstrual secretion consists of blood effused from the mucous membrane of the uterus, mixed with the mucous secretion of the passages. It coagulates less rapidly than ordinary blood, and exhibits as a rule an acid reaction. The value of *M.* and its irregularities as symptomatic of uterine and ovarian disease can hardly be over-estimated.

Diseases of M.—When *M.* is absent at the normal period of life, the disease is termed *Amenorrhæa* (q. v.); and when the discharge is excessive in quantity, and more than naturally frequent in occurrence, it is termed *Menorrhagia*. Uncomplicated menorrhagia generally depends upon debility, and is most successfully treated by the administration of tonics, the topical application of cold on the lumbar region, and over the lower part of the abdomen, and also by cold astringent injections. When the normal discharge is attended with much pain the affection is termed *Dysmenorrhæa*. This condition may depend upon a congenital state of the *os* or *cervix uteri*; or of the *uterus* itself; but it is more frequently a symptom of some disease of the Uterus (q. v.). It frequently happens that *M.* is perverted through other channels than the natural one, as the lungs and the nose, the rectum and the skin, such cases being called *vicarius M.*

Mensura'tion is the branch of applied mathematics which treats of the measurement of the areas of surfaces and of the volumes of solids. To the surveyor and gauger a knowledge of its methods is indispensable; and a knowledge of its principles, which in the main depend upon the simplest geometry, though not absolutely necessary, is distinctly to be desired. The rectangle is the simplest possible figure of which the area can be calculated, and after it come parallelograms and triangles of every description, and all polygons which can be broken up into triangles. When the one side of a figure is curved, the calculation of its area is in general less simple, and as a rule methods of approximation are alone applicable. The ordinary method is to break up such a figure into parts, which may be treated as true rectilinear polygons, and then sum the area of the parts to find the area of the whole. The same remarks apply to the calculation of volume in which the rectangular parallelepiped occupies the same position which the rectangle does in the measurement of areas. When one of the bounding surfaces is curved, the same methods of approximation must be adopted, except in particular cases, when the figure is one of the simpler surfaces of revolution of the second degree. See **SURVEYING**, **TRIANGULATION**, **TRIGONOMETRY**, &c.

Menta'na, a small Italian village, 13 miles N.E. of Rome, noted for a battle fought November 3, 1867, in which Garibaldi was defeated by the combined French and Papal troops. On his retreat he was taken prisoner by the Italian regulars of Victor Emmanuel. In honour of the victory the pope instituted the *M. medal*.

Mento'ne (Fr. *Menton*), a town of France, department of Alpes Maritimes, on a beautiful bay of the Gulf of Genoa, 14 miles from the Italian frontier, and 2 E. of Nice by rail. Its delightful climate attracts invalids from all parts of Europe,—the lowest winter temperature for ten years, according to Dr. Siordet, being 48° 75'. The Maritime Alps, rising to a height of 4000 feet, are flanked by luxuriant orange, lemon, and olive groves, and between them and the sea winds the only level road, the Cornice. Near *M.*, and 88 feet above the sea, are celebrated bone-caves, rich in pre-historic remains. A fossil human skeleton, now in the Paris Museum of Natural History, was found here, March 26, 1872. *M.* has a brisk trade in fruits, fish, and perfumeries. Pop. (1872) 5540. Formerly attached to Monaco, *M.* was transferred to France by vote of the inhabitants in 1860, and on payment of four million francs.

Mén'tor, a son of Alcimus, and friend of Odysseus, who intrusted to him his house on setting out for Troy. In the second *Odyssey*, Athena, in the form of M., conducts Telemachus to Pylos. From Fenelon's portraiture of her thus disguised M. has become an appellation for a 'guide, philosopher, and friend' of youth.

Menu. See MANU.

Menu'ra. See LYRE-BIRD.

Menza'leh Lake, the largest lagoon of Lower Egypt, extends eastward from Damietta, and is only separated from the Mediterranean by a narrow line of sandbanks, pierced by several openings. It is 50 miles long by 25 broad, has a depth of from 1 to 10 feet, is studded with islands, and abounds in fish and wildfowl. The Suez Canal (q. v.) traverses it from Port Said to Kantara, a distance of 27 miles.

Menzel, Wolfgang, a German historian, novelist, and critic, born at Waldenburg in Silesia, 21st June 1798, took part in the war with France in 1815, after which he studied philosophy at Berlin and Bonn. From 1825 he lived at Stuttgart, devoting himself almost entirely to literature, and died there, April 23, 1873. His first work was *Streckerse* (1823), a critical work, strongly opposing the popular views of poetry and the excessive praise of Goethe. This is also the tenor of his *Europäische Blätter* (1824-25), *Literaturblatt* (1825-48), and *Die Deutsche Literatur* (1828). In 1837 Börne called him 'Der Franzosenfresser,' from his bitter opposition to French influence in German literature. Of political history M. has written *Geschichte der Deutschen* (1824-25; 5th ed. 5 vols. 1856; Eng. trans. 3 vols. 1848), *Geschichte der letzten 120 Jahre* (6 vols. Stuttg. 1460; continued in 3 vols. to 1870), and *Allgemeine Weltgeschichte* (12 vols.; 2d. 1862, et seq.), in a piquant and racy style, if somewhat one-sided spirit. He is also favourably known as the writer of the novels, *Rübenahl* (1829), *Narcissus* (1830), and *Purora* (1851); *Mythologische Forschungen* (1842), *Die Gesänge der Völker* (1851), *Christliche Symbolik* (1854), *Naturkunde im Christlichen Geist* (3 vols. 1851-57), and *Deutsche Dichtung* (3 vols. 1858-59).

Mephistoph'elos, in the Faust legend, is the *famulus* of that famous magician. Old German chapbooks and puppet-plays give three spellings of his name, M., Mephistophiles, and Mephistophilis, the last being also the form adopted by Marlowe, whilst Shakespeare (*Merry Wives of Windsor*, act i. sc. 7) has a fourth variant, Mephistophilus. The etymology again of the name is doubtful, whether it is a barbarous Greek compound, *mē-phōsto-phīlēs*, 'not loving the light'; a derivative of the Lat. *mephitis* and Gr. *philos*; or, as is most probable, from two Hebrew words, *mephir*, 'destroyer,' and *tophel*, 'liar.' The wholly human, mirthful, sneering M. of the medieval legend, invested by Marlowe with 'an awful melancholy,' stands forth in Goethe's drama as the spirit that denies, 'the devil,' as Carlyle says, 'not of superstition but of knowledge.' See FAUST.

Mepp'el, an old town in the Netherlands, province of Drenthe, at the junction of several canals and streams which flow into the Zuider Zee, 9 miles distant, by the Meppeler Diep. It has considerable linen manufactures and trade in agricultural products. Pop. (1870) 6644.

Mercantile Law. Efforts to make a *Codification* (q. v., under *Code*) of international M. L., appear to have been co-existent with the medieval development of European commerce. Of the results of these, the earliest of note is the *Consolato del Mare* (q. v.), constructed towards the end of the 13th c. from the trading laws and customs of the great commercial cities of the Mediterranean; these laws and customs having had their origin in the Roman law, the mercantile part of which again was founded on the laws of Phœnicia and Carthage. Along with English law in general, the M. L. of England, gradually, as its connection with France became severed, diverged from the Continental system, and it deteriorated in consequence of its isolation. Lord Mansfield appears to have been the first English judge who re-directed the footsteps of English law towards the path followed by European nations in general, and subsequent authorities have shown much legal acumen in developing in England the doctrines of Roman M. L. as adopted by modern Continental jurisprudence. Endeavours have frequently been made to assimilate the mercantile laws of England and of Scotland, in the latter of which countries M. L. has always been carefully and successfully

cultivated. A result of this endeavour is the *M. L. Amendment Act*, 19 and 20 Vict. c. 97, which makes various regulations respecting bills of exchange. See *Bill of Exchange*, under BILL. The 19 and 20 Vict. c. 60, for assimilating the mercantile laws of the two kingdoms, enacts that no acceptance of a bill of exchange, inland or foreign, in Scotland, shall bind the acceptor unless it be in writing.

Merca'ra (Mahadwape, 'the town of Siva'), the capital of the state or province of Coorg in S. India, on a tableland 4506 feet above the sea, 130 miles S. W. of Bangalore and 315 W. of Madras: pop. (1871) 8146. It was founded about 1681, and the fort, built in 1773 by Hyder Ali, was restored to the native Rajah by the treaty with Tipoo Sultan in 1792, but in 1832 it was occupied by the British, and has ever since been the headquarters of our administration. In the neighbourhood is a promising plantation of cinchona.—The district of M. has an area of 265 sq. miles; pop. (1871) 32,132.

Merca'tor's Projection, a convenient method of projecting and developing the surface of the earth so as to represent the whole of it, with the exception of the portions near the poles, upon one continuous plane surface. Assuming the earth to be a sphere, conceive a right cylinder with its axis coincident with the earth's axis to be circumscribed round it. Every point upon the earth's surface is projected upon the cylinder by simply producing the radius through that point till it meets the cylinder. The cylinder is then unrolled to a plane. The countries in the higher latitudes are, of course, upon a larger scale than those in the equatorial regions; but the length is extended in the same proportion as the breadth, and therefore the shape of a given district suffers no distortion. The meridians are represented by equidistant parallel lines, while the parallels get farther and farther from each other as the latitude increases. The poles are at an infinite distance, and therefore cannot be represented upon such a chart; but this is of no practical moment.

Merchant Shipping Act, 17 and 18 Vict. c. 104, deals with questions of marine discipline, with the legal rights of seamen, with the relative rights and duties of the Board of Trade, and of ownership, with questions of Wreck and Salvage (q. v.), and of Pilotage (q. v.), and generally amends and consolidates the entire statute law relative to merchant shipping. Act 36 and 37 Vict. c. 85 deals with the agreements of seamen under the former Act, and gives them compensation for unnecessary detention on charge of desertion. The Act also empowers the Board of Trade to establish mercantile marine offices, and to hold examinations at certain ports.

Merchants' Marks See TRADE MARKS.

Mercur'ius (from the same root as *merx*, 'merchandise,' *mercari*, 'to buy'), the Roman god of trade and gain, identical with the Etruscan Turms. M. was also identified by the later Romans with the Greek Hermes (q. v.), but to this the Fœciales (q. v.) always objected, owing to the very slight resemblance between the two conceptions. The festival of M. fell on the 15th of May, when merchants were wont to sprinkle themselves and their goods with the water of a well sacred to the god, which was near the Porta Capena. M. had a temple at Rome as early as 495 B.C., and as *M. Malevolus* he had a statue in the *Vicus Subrius*, where buying and selling were forbidden, and libations were poured to him of milk instead of wine.

Mer'cury, or **Quick'silver** (atomic weight, 200; symbol, Hg, from Lat. *hydrargyrum*), a metallic element, and the only known metal which is liquid at the ordinary temperature, solidifying at $-39^{\circ}44$ C., and boiling at 360° C. At ordinary temperatures its specific gravity is 13.6. Its specific heat is small, and its almost constant coefficient of expansion for moderate temperatures has made it invaluable in thermometry. (See THERMOMETER.) It is frequently found native, but the chief source is the mineral cinnabar, a sulphide of M. (HgS), which is procured usually from Idria in Austria, from Almaden in Spain, from China, and from New Almaden in California. The metal is obtained ordinarily by roasting the sulphide with lime, when the M. passes off in vapour, leaving sulphate of lime behind. There are two oxides, the black or mercurous oxide (Hg₂O), and the red or mercuric oxide (HgO). The former is obtained by decomposing the mercurous chloride with solution of potash, and washing with water. It is easily decomposed by the action of light, or a gentle

heat, into mercuric oxide and the metal. *Mercuric oxide* is formed on the surface of M., when the metal is heated in air near its boiling point. It is black when hot, but red when cold. It is ordinarily prepared by calcining the nitrate of M., when it is obtained as a red crystalline powder, known in the arts as *red precipitate*, which is completely decomposed into its elements at a red heat. Both the oxides combine with acids to form salts, which are distinguished as mercurous and mercuric salts respectively. M. forms two chlorides, *calomel* or mercurous chloride (HgCl), and *corrosive sublimate*, or mercuric chloride (HgCl_2). The latter is formed by heating together common salt (NaCl) and the sulphate of M., which is first obtained by evaporating to dryness a mixture of two parts by weight of the metal with three parts of strong sulphuric acid. The corrosive sublimate, as the name implies, condenses from the vapour state in the cooler part of the vessel in heavy, lustrous, but colourless masses. It is soluble in water, alcohol, and ether, melts at 265°C ., and boils at 295°C . When a solution of it is mixed with ammonia, the *white precipitate* of pharmacy, chemically known as the amido-chloride of M. (HgNH_2Cl), results. Calomel is insoluble in water, and is obtained as a dingy white precipitate, when a soluble chloride is added to mercurous nitrate. It is most easily prepared by subliming an intimate mixture of corrosive sublimate and M. ($\text{HgCl}_2 + \text{Hg} = 2 \text{HgCl}$). Mercuric iodide is a brilliant scarlet powder, which, if dissolved in potassic iodide, with the addition of a little M., gives a very delicate test for detecting ammonia, known as *Nessler's test*. M. forms two sulphides, the black mercurous sulphide (Hg_2S), Ethiop's mineral of old writers, being, however, a very unstable compound, decomposing readily into the metal, and the mercuric sulphide (HgS). The latter is the principal ore of M., some varieties of which, from their brilliant colour, are called *vermilion*. M. unites readily with other metals to form what are known as *amalgams*. This property is turned to useful account in the extraction of gold and silver from their ores, in the silvering of looking-glasses, and in the *amalgamating* of the zinc plates of a galvanic battery.

Medicinal Properties of M.—M. was first employed, medicinally, by the Arabian physicians Avicenna and Rhazes, but they only used it externally against vermin, and in cases of cutaneous disease. Paracelsus was the first European physician to recommend its use internally. M. was formerly given in a liquid state, with a view of overcoming, by its weight, obstructions in the intestinal canal, but it is not so used now; and as a metal it is seldom given alone, and only in a state of minute subdivision. M. is cholagogue, purgative, and alterative, and powerfully affects the mucous membranes of the intestinal canal and the salivary glands. It is absorbed in all the tissues of the body. It is chiefly used in cases of congestion, in acute and chronic inflammation, and specially in syphilis and certain forms of ophthalmic disease. It is applied externally as a topical stimulant to indurated and chronically inflamed parts, and sometimes with the view of its being absorbed into the system. M. is much less frequently, and more cautiously, administered than formerly, and, being a dangerous remedy, it should never be used except under medical supervision. The pharmaceutical name of M. is *Hydrargyrum*, and there are many preparations of it in the British Pharmacopœia.

Mercury, the nearest known planet to the sun. Its greatest and least distances are 42,669,000 and 28,115,000 miles respectively, giving an eccentricity of .2056. The mean sidereal year is 87.9693 days; but the period of rotation assigned (24h. 5m. 28s.) cannot be regarded as established, on account of the difficulty of getting a proper view of the surface. At its greatest elongation it appears only as a half disk, and its proximity to the sun renders it a very unfavourable object for observation. The orbit is inclined 7° or $8''$ to the ecliptic; but the inclination of the equator is not known. Its diameter is estimated at 3050 miles; its volume $\frac{1}{4}$ that of the earth; and its density $\frac{1}{4}$ greater than the earth's. Transits of M. across the sun's disk are frequent, and are important to the astronomer as affording him opportunities of observing the peculiarities of such phenomena, which are of so great value in the case of Venus (q. v.). The orbital motions of M. show irregularities which, according to Leverrier, indicate the existence of intra-mercurial planets, whose combined mass is comparable to that of M.

Mercury, Dog's (*Mercurialis*). A genus of erect herbs, belonging to natural order *Euphorbiaceæ*, and of which six

246

species are recorded. Two of these are natives of Britain. Common Dog M. (*M. perennis*) is plentiful in woods and shady places, forming extensive patches of a dark-green hue. It is a poisonous plant. The annual Dog M. (*M. annua*) is becoming more widespread as a weed in the outskirts of towns, but it is questionable whether it holds a grade of nativity higher than that of a colonist. On the Continent the leaves are boiled and eaten as a pot-herb. The prefix 'dog's' denotes worthlessness, and is properly confined to the first-named species. The English M. or all-good, a desirable pot-herb, is *Chenopodium Bonus Henricus*.

Merganser (*Mergus*), a genus of *Natatorial* or swimming birds, forming the type of the sub-family *Mergina*. The bill is slender, and hooked at the tip, its edges being notched, and the horny notches aid the bird to secure fishes. The wings are pointed, and have their first and second quills longest. The tail is short and rounded, and the great toes are united by a web, the hinder toe being lobed. The M. inhabits northern regions. The goosander (*M. castor*) is a good example of the M., and the *M. serrator*, the sandhill or red-breasted M., and hooded M. (*M. cucullatus*) are also well-known species. The latter is common in N. America. The allied genus *Mergellus*, includes the smew (*M. albellus*) and other birds. The smew is a winter visitant to the shores of England, and has a white head and neck, a black back, and a grey tail.

Merganser (Hooded).

Mer'gui, the chief town of the district of the same name in British Burmah, on the sea-coast: pop. (1872) 10,200. In 1874-75 the exports were valued at £46,894; the imports at £39,260.—The *district* of M., a narrow strip between the sea and the mountains, forms the extreme S. of British territory, and geographically belongs to the Malay peninsula: area, 7760 sq. miles; pop. (1872) 47,192, the sparsest population in all British India. The products are timber and tin; coal has been found. The *M. Archipelago* consists of a cluster of islands off the coast, of granite formation, some of which are 3000 feet high. They are infested with wild beasts, and thinly inhabited, but are visited by the Malays and Chinese for the sake of the edible bird's nest.

Merida, (1) a town of Spain, in the province of Badajoz, on the right bank of the Guadiana, and 33 miles E. of Badajoz by rail. A decayed place, with a pop. of 3800 inhabitants, it has been called the 'Rome of Spain,' from its noble monuments of antiquity, which include an amphitheatre, naumachia, aqueduct, several triumphal arches, and a bridge of eighty-one arches. M. was founded (B.C. 23) as a *colonia* of the retired veterans (*emeriti*; hence the name) of the 5th and 10th legions, speedily rose to be the capital of Lusitania, with a garrison of 90,000 men, was taken by the Moors (713), and recovered by Alfonso IX. (1230).—(2) A town of Mexico, capital of the state of Yucatan, 28 miles S.W. of the seaport of Sisal, has a noble cathedral (1598), thirteen churches, a bishop's palace, decaying university, four newspapers, and manufactures of sugar, tobacco, ropes, and leather. It was founded (1542) by Francisco de Montijo on the site of the Indian *Tihu*. Pop. 33,025.—(3) A town of Venezuela, capital of the province of the same name, 151 miles S. of Maracaybo, is the seat of a bishop, has a college and seminary, and carries on a trade in coffee, cotton, and woollen fabrics, carpets, &c. It was founded (1558) by Juan Rodriguez Suarez, and in 1812 was almost destroyed by an earthquake. Pop. (1873) 9727.

Meriden, a town of Connecticut, U.S., on the New York, New Haven, and Hartford railway, 94 miles N.E. of New York. It has extensive manufactures of woollens, silver-plated articles, cutlery, and hardware generally. Pop. 10,495.

Meridian of a place is the great circle which passes through it and the poles, and by means of which the *longitude* of the place is determined. See LATITUDE and LONGITUDE. The *magnetic M.* of a place is the intersection of the earth's surface with the vertical plane in which a freely suspended vertical

needle lies. The angle which it makes with the true M. is called the *declination* or *variation* of the needle. See TERRESTRIAL MAGNETISM.

Mérimeé, Prosper, a French litterateur, was born at Paris, 28th September 1803, educated at the Charlemagne College, early made an acquaintance with English and Spanish literature, and became one of the pioneers of the Romantic School. His first work appeared in 1825 under the title of *Théâtre de Clara Gasul, Comédienne Espagnole*, and professed to be a collection of prose translations from the Spanish drama. It exercised a great influence; it may even be said to have precipitated the revolution in favour of the new literature. In 1827 *La Gusla* followed, the result of some reading in the field of Slavonic poetry. During the next ten years there appeared in rapid succession, in the *Revue de Paris* and the *Revue des Deux Mondes*, romances, numerous novelettes, historic episodes, &c., of which the chief are *Tamango*, *La Prise de la Redoute*, *La Venus d'Ille*, *Les Ames du Purgatoire*, *La Vision de Charles IX.*, *La Peste de Tolède*, *La Partie de Trictrac*, *Le Vase Étrusque*, and *La Double Méprise*. M. took office after the Revolution of 1830, and in 1834 became inspector-general of historical monuments. His travels in this latter capacity through Corsica resulted in the romance of *Colomba* (1841), which Sainte-Beuve chooses to compare with the *Electra* of Sophocles. It is a masterpiece of studied character, with an accurate delineation of scenery and customs. Three or four volumes of travels were also the product of his observations during this period. History then occupied his attention more exclusively, and in 1844—the year in which he was elected a member of the French Academy—there appeared his *Études sur l'Histoire Romaine; Histoire de Don Pièdre I.*, in 1848; *Mélanges Historiques et Littéraires*, in 1855. During the same period he contributed to the magazines some valuable criticisms in art. In 1853 M. was appointed a member of Senate, and in 1858 president of a commission for reorganising the imperial library. He was also nominated Commander of the Legion of Honour in 1860, and a member of the Academy of Inscriptions. M. died at Cannes in October 1870. In 1872 appeared the posthumous *Lettres à une Inconnue*, followed in 1875 by *Lettres à une Nouvelle Inconnue*, both of which excited quite a sensational interest in France. M. had a vivid, dramatic, and delicate talent; and his originality of criticism was finely controlled by good sense and elegant scholarship. See Sainte-Beuve, *Portraits Contemporains* (vol. i. and ii.), *Causeries du Lundi* (vol. vii.).

Merino. See WOOLLEN MANUFACTURES.

Merino, also named the 'Spanish Sheep,' is a familiar variety or breed of sheep, largely bred in Europe, Australia, and America. The M. originally came from Spain. In 1464 some of the Cotswold breed of English sheep were sent to Spain, and the mixed breed produced from these sheep and the M. may be held to represent the modern breed of M. These sheep are cultivated for the sake of the wool; the flesh, although palatable, being surpassed by that of other breeds, and the feeding of the M. being very expensive. The M. sheep has large and strong limbs, and the horns of the male are large and spirally twisted. The female is usually hornless. The black tint which occasionally crops out in the M. is greatly improved or even altogether abolished by careful breeding. Immense herds of M. sheep are reared in Spain: they are kept in the mountains in summer, but are drawn to the winter pastures about September.

Merioneth (named after *Merion*, an ancient British champion), the most mountainous county of Wales, is bounded N. by Carnarvon and Denbigh, S. by Cardigan, E. by Montgomery, and W. by Cardigan Bay. Area, 602 sq. miles; pop. (1871) 46,589. Its coast-line, 38 miles long, is in part sandy and in part cliffy, and a considerable area has been reclaimed in Traeth Mawr, Traeth Bach, &c. M. is a highly romantic country of wild and volcanic peaks, and fair, fertile valleys, of resounding cataracts and beautiful highland lakes. The greatest heights are Arran Mowddu (2955 feet) and Cader Idris (2914); the principal rivers are the Dee, Dovey, and Mawddach; and the largest lake is Bela, which, like the smaller lakes, abounds with trout and other fish. In 1876 there were 17,783 acres under corn crops (chiefly oats, barley, and wheat), 4220 under green crops (potatoes, turnips, and Swedes), 15,362 in clover, sanfoin, and grasses, and 113,698 in permanent pas-

ture, exclusive of mountain-land and heath. The number of horses (1876) was 5808, of cattle 41,002, of sheep 376,986, and of pigs 10,087. Other products are lead, copper, slates, and limestone; gold was found in considerable quantity in several places about the year 1866, but the working has since proved unproductive. The inhabitants, who mostly speak Welsh, manufacture some flannel, woollens, and hosiery. The chief town is Dolgelly. M. returns one member to Parliament.

Merivale, (1) **John Herman**, an English scholar, born at Exeter, August 5, 1779, studied at St. John's College, Cambridge, joined the bar in 1805, and became Commissioner in Bankruptcy in 1833. He published *Chancery Reports* (3 vols. 1815-17), and was author of part of *Translations from Greek Anthology* (1806), *Collections from the Greek Anthology* (1833), *Poems Original and Translated* (2 vols. 1828-38), and an admirable translation of the *Minor Poems of Schiller* (1844). He died April 25, 1844.—(2) **Herman**, economist, son of the preceding, born in 1805, studied at Oxford, was called to the bar in 1832, and appointed Professor of Political Economy in Oxford in 1837. His *Lectures on Colonisation* (1841-42; new ed. 1861) are most important contributions to that subject. He was Under-Secretary for the Colonies 1848-59, and for India 1859-74. He published *Historical Studies* (1865), completed and edited the *Memoirs of Sir Philip Francis* in 1867, and was joint-author of a *Life of Sir Henry Lawrence* (1873). He died February 8, 1874.—(3) **Charles**, Dean of Ely, brother of the preceding, born in 1808, studied at St. John's, Cambridge, of which he became a fellow and tutor. He was select preacher to the University (1838-40), preacher at Whitehall (1839-41), Rector of Lawford, Essex (1848-69), Hulsean Lecturer, Cambridge (1861), Boyle Lecturer (1864-65), chaplain to the Speaker of the House of Commons (1863-69), and Dean of Ely (1869). He is author of a scholarly *History of the Romans under the Empire* (8 vols. 1850-65), *The Conversion of the Northern Nations* (Boyle Lectures, 1864-65), a translation of the Iliad into rhymed verse (2 vols. 1869), a *General History of Rome* (1875), &c.

Merle D'Aubigné, Jean Henri, a well-known ecclesiastical historian, descended from a Calvinistic family of Nîmes, was born near Geneva, 16th August 1794, studied in his native place and at Berlin, for five years acted as French pastor to the Protestants of Hamburg, and until 1830 as chaplain at Brussels to King William. He then became Professor of Church History at Geneva, where, with the exception of travels in England and Scotland, he steadily devoted himself to the publication of sermons and treatises. The work which entitles him to a place in literary history is his *Histoire de la Réformation au seizième Siècle* (5 vols. Par. and Gen. 1835-53; 2d ed. 1861-62). It is written with animation, eloquence, and faith in the finality of the Reformation, and the English translation has obtained an immense circulation in England and the United States. M. died at Geneva, 21st October 1872. It was continued by his *Histoire de la Réformation en Europe au Temps de Calvin* (3 vols. Par. 1863-65). His other works, *La République d'Angleterre aux Jours de Cromwell* (Par. and Gen. 1849), and *Trois Siècles de Luittes en Écosse*, may be regarded as contributions to the great history to which he devoted his life.

Merlin (*Hypotriorchis asalon*), a species of *Falconide* or Falcons (q. v.), also named the 'Stone Falcon,' from its habit of perching upon stones. It is the smallest of British falcons, attaining only a length of from 10 to 13 inches. The sexes vary in colour. The general colour is a slate-grey, mottled with dark or blackish streaks, while a brown tint predominates in the body feathers. The chin and throat are white, the under parts a reddish-fawn; and the legs and toes yellow. The plumage of the female has more brown than that of the male. The M. is readily trained to fly at game. It is a sharp, active, and courageous bird, and will follow its quarry with great persistence. Its flight is usually low, but it shoots upward in a spiral manner, and is able to ascend with great swiftness. The M. is common in Europe, N. and S. Africa, N. America, and is found in N. Asia. Allied to the M. are the American Pigeon Hawk, and the Cliquera Falcon of India.

Merlin, a famous magician and prophet of the Arthurian Romance. There is no reason for supposing him to be a historic character. Neither Gildas, nor the Chronicle, nor Bede knows

anything of his existence. He first appears in Nennius (8th or 9th c.), but not by name. In chap. 40-42 of Nennius' chronicle there is a story of a boy magician called *Ambrosius*, who surpasses in sagacity all the wise men of King Vortigern. This incident is woven into the history of M. first found in the *Historia Brittonum* of Geoffrey of Monmouth, but whether M. is a creation of the Archdeacon's lively fancy or the distorted expression of some older legend, it is impossible to tell. The name may be a Latinised form of the Welsh Myrddin (q. v.), and some traditions of the ancient Welsh bard may have started the wild myth of the middle ages. His name soon spread, and by the romantic poetry of the Trouvères was carried over all Western Christendom. In the article ARTHUR it has been shown that the scene of that leader's exploits was Strathcumbria, not Wales, the northern not the southern Cymric Land; and if we could put any faith in the medieval romance which associates M. with Arthur, it would be the *M. Caledonius* in whom we should look for some traces of reality. Of this M. there is a metrical life, professing to be based on Armoric materials, which was published by the Roxburghe Club in 1830. But as Geoffrey of Monmouth removes Arthur to S. Wales, so M. is carried thither also. He is represented as the result of the intercourse of a demon with a Welsh princess, as endowed with miraculous powers, and as the adviser in succession of Vortigern, Ambrosius, and Uther Pendragon, and the author through medicinal enchantments of Arthur himself. He is known as *M. Ambrosius*, and in the Romances—both French and English—is the worker of thousands of impossible marvels. In the Advocate's Library in Edinburgh there is a MS. romance (unfinished) on *M. Ambrosius*, which was published by the Abbotsford Club in 1848. Tennyson's Idyll of *Vivien* has worked a miracle which the magician himself could not work—it has restored him to life after the lapse of a thousand years. See F. von Schlegel, *Geschichte des Zaubers* M. (Leips. 1804); Villemarqué, *Contes Populaires des Anciens Bretons* (2 vols. Par. 1842); Grässe, *Sagenkreise des Mittelalters* (Dresd. 1842).

Mermaids ('sea-maids'), the name given to certain fabulous creatures that were said to present in their upper parts the likeness of a woman, the lower part of the body terminating in a fish-like tail. The medieval M. is identical with the ancient 'siren.' Perhaps the most exquisite embodiment of the idea is the 'Lorelei' of the Rhine, made immortal by the genius of Heine. In the lists of zoology there are certainly to be found marine animals which present a singular resemblance to the human face and figure. Thus the seals have countenances of a very human type, and the same remark may be made of the manatees or sea cows and dugongs. It is noteworthy that the latter animals have the habit of raising themselves into a semi-erect posture in shallow water, and as the mammary glands are situated on the breast, the resemblance to the form of a female figure is by no means far-fetched, especially when the animals are viewed from a distance. It has also been alleged that the young are held to the breast by means of the 'flippers,' or forelimbs. If this statement be true, there can be no doubt that it adds greatly to the likelihood that these animals represent the 'sirens' of old navigators, and the 'mermaids' of medieval or modern sailors.

Mermaid's Glove, the popular name of a species of Sponge (q. v.) common round the British coasts, and known scientifically as the *Halichondria palmata*. The popular name is derived from its somewhat finger-like shape. It is of a pale yellow colour, and may attain a height of 2 feet, although specimens of smaller size are more common.

Merrimack, a river of New England, U.S., rises in New Hampshire, flows S. into Massachusetts, where it winds N.E., entering the Atlantic at Newburyport, after a course of 130 miles, of which 15 are navigable. It is chiefly important for the water-power it gives to Concord, Manchester, Nashua, Lowell, Lawrence, and Haverhill, and its navigation is being extended (1877) by the Government. Below Lawrence there are valuable fisheries. At the mouth a shifting bar greatly impedes commerce.

Merseburg, an old town of Prussia, province of Saxony, on the Saale, 60 miles S.S.E. of Magdeburg by rail. It has a grand cathedral, founded in the 10th c., now consisting of a choir of the 13th, and a late Gothic nave of the 15th c., and containing a magnificent organ (4000 pipes) and a brass monument of Rudolf

of Swabia, who was slain in a battle against Heinrich IV. in 1080. The castle, an imposing structure of the 15th c., with many towers, was once a residence of the Saxon princes. M. has manufactures of cottons, woollens, tobacco, paper, &c., and its beer is considered about the best in Germany. Near M. the Hungarians were defeated by Heinrich the Fowler in 934. Pop. (1875) 13,678.

Mersey, a river of England, is formed by the Thane and Goyt on the N. border of Derbyshire, flows in a westerly direction, receiving the Irwell, Bollin, and Weaver, separating Cheshire and Lancashire in its lower course, and expanding below Runcorn Bridge, and 16 miles from its mouth, into an estuary—the Liverpool Channel—from 1 to 3 miles in breadth. It is about 70 miles long, and is navigable to its junction with the Irwell, the difficulty of its sandbanks being obviated by an excellent system of pilotage. The M. has fisheries of flounders, congers, shrimps, and sparlings.

Merthyr-Tydvil (named after the daughter of an ancient British king), a town of S. Wales, on the N. border of Glamorganshire, and at the confluence of the greater and lesser Taff and the Morlais and Dowlais streams, 23½ miles N.N.W. of Cardiff by rail. Surrounded by hills 500 feet above the sea level, it is a great railway centre and a metropolis of the iron industry, but presents a mean, murky appearance. It has a good drainage system and water-supply (since 1865), and the death-rate, formerly excessive, has been materially lowered of late years through the improvements made by the Local Board of Health. With little to boast of architecturally, M. has (1877) 2 Established churches, 15 Dissenting chapels, a market-house, theatre, Temperance Hall, and Drill Hall. The collieries and ironworks of the district are of vast magnitude, and probably comprise more than half the number throughout Glamorganshire. The output of finished iron consists chiefly of iron and steel rails, bars, girders, and ship-plates. The great bulk of the inhabitants are Welsh, and are employed in the ironworks as labourers, comparatively few being skilled workers. There is a very large trade in fine steam coal, which is chiefly sent by rail to Cardiff, Newport, and Swansea for exportation. In the vicinity are the extensive works of Dowlais (q. v.), Cyfarthfa, Plymouth, and Pen-y-daren, the three last, owing to the stagnation in the iron trade, having been stopped for some years. Cyfarthfa Castle, about 1½ miles from M., is the home of the Crawshays, the great ironmasters. Pop. (1871) 51,949; of parliamentary borough, which includes Aberdare and two other outlying districts, 97,020. M. returns two members to Parliament.

Merton College, Oxford, was first founded at Malden in Surrey (1264), and transferred to Oxford (1270), by Walter de Merton, Bishop of Rochester, and Lord High Chancellor of England. The foundation consists of a warden, 34 fellows, 18 post-masters (2 of them collegers of Eton), 4 scholars, 2 exhibitioners, and 2 chaplains. The hall, chapel (with a lofty tower, fine stained glass, brasses, ancient tapestry, &c.), and library, are among the most ancient and beautiful of Oxford buildings, and have been recently restored by Sir Gilbert Scott. M. C. presents to 18 livings, and in 1876 had 175 members of Convocation, 76 undergraduates, and 295 members on the books.

Merulidæ, or **Turdidæ**, a family of Insectorial birds represented by the blackbirds, redwings, and others of the thrush group, the orioles, &c. The bill is strong, and has its sides compressed. The wings are long, but the tail is of moderate length. This large group includes many sub-families, such as the *Formicarinæ* (ant-thrushes), *Oriolinæ* (orioles), *Timalinæ*, &c.

Merwings, or **Merwing Dynasty**, takes its name from Merowig, a Frankish chief of the 5th c., and was founded by Hlodowig, who put an end to the Roman rule in Gaul, adopted Christianity, and became the sole head of his race. At his death in 511 A.D. there was a partition of his estates among his four sons, Theodorik getting Austrasia, Hildebert the country round Paris and Armorica, Hlodowir, Orleans and the W. of Gaul, Hlotair, Soissons. Hlotair became in time sole king, and in 567, after his death, Frankish Gaul was divided into the three kingdoms, Austrasia, Neustria and Burgundy, which, being distributed among four kings, were for ever at war. In 595 the Frankish empire was under the kingship of three children, each of which had a mayor of the palace, but in 613 Hlotair II. became sole king, and was succeeded in power by Dagobert I.,

who fixed his throne at Paris, and raised the Meroving monarchy to the highest point it ever reached. On his death in 638 the dynasty may be said to have practically terminated. Henceforth, until 752, when Hilderik III. was deposed by Pippin, their kingship was merely nominal, all real power being concentrated in the hands of the mayors of the palace. The later M. are called by French historians *Rois fainçants* ('Do-nothing kings'). See Kitchin's *History of France* (vol. i. 1873).

Mesagna (anc. *Messapia*), a walled town of S. Italy, province of Lecce, beautifully situated 9 miles W. of Brindisi. It has a trade in fine oil and fruits, and near it are many old sepulchres and broken columns. Pop. (1874) 8511.

Mesembryanthemum, a natural order of plants with thick succulent opposite leaves, solitary-stalked flowers, consisting of numerous petals and stamens of brilliant colours opening in the sunshine, and a capsular fruit embedded in the calyx. It comprises fully 400 species, the greater portion belonging to the genus *Mesembryanthemum*. With a few exceptions they are natives of S. Africa, growing in dry, hot, sandy places. They vary exceedingly in the form of their leaves, often having them three-sided, with a toothed margin resembling the jaws of various animals, giving current names of tiger-jaws, dog-jaws, cat-jaws (*M. tigrinum*, *M. caninum*, *M. felinum*), to different species. The capsules after ripening shut and expand according to the moist or dry state of the atmosphere, and are often brought home as curiosities. The fruit of the Hottentot fig (*M. edule*) is eaten by the Hottentots, and that of *M. aquilaterale* by the natives of Australia; both yield a really palatable food. Upwards of 250 species have from time to time been brought into cultivation by botanical amateurs.

Mesentery (Gr. *meson*, 'the middle,' and *enteron*, 'the intestine') is the name given to the broad fold of the *peritonæum* or lining membrane of the abdomen, which supports the various viscera or organs of the digestive system, and which especially attaches the intestines to the spinal column. The M. proper originates from the left side of the second lumbar vertebra, and extends across the spine to the right side in an oblique fashion, being attached to the cavity or hollow of the right iliac bone. The edge of the M. to which the intestine is attached is puckered or thrown into folds. The M. specially supports that portion of the intestine which lies between the jejunum and the cæcum. It attains a breadth of 4 inches, and at its lower border divides into two layers which enclose the intestine, and afford support to the mesenteric nerves, vessels, lymphatics, and glands.

Mesenteric Disease.—The **Mesenteric Glands** are subject to all those diseases which implicate the glandular system, but they are specially affected in many diseases, such as typhoid or enteric fever, in which they are invariably enlarged at the very commencement of the disease. One form of scrofulous disease exceedingly common, especially among children, is called *Tubercles mesenterica*, the term *tubercles* being the Latin equivalent for the terms phthisis and consumption. The mesenteric glands enlarge and become charged with tubercular matter, the enlargement being commonly connected with scrofulous disease, and ulceration of the mucous follicles of the intestines, interfering with the functions of the lacteal vessels, and the consequent supply of nutriment to the body. During the periods of childhood and youth the lymphatic glands, especially the mesenteric and the cervical, are exceedingly prone to scrofulous inflammation, from the secretion or separation of the matter of tubercle from the blood; but in adult age tubercles are most frequently deposited in the respiratory organs; or, in other words, consumption, among children, is most frequent in the abdomen, constituting the disease *tubercles mesenterica*, and among adults, in the lungs, the disease being named *pulmonary consumption* or *phthisis*. In the earlier stage of *tubercles mesenterica* the only indications are the symptoms of general tuberculous disease of which the disease of the mesenteric glands is usually but a subordinate part. At a later period the symptoms are generally much the same as those of tubercular peritonitis; but if the peritonæum be free from disease, the abdomen is less tense and less tender, and the large glands present an irregular, nodulated surface which can be detected through the abdominal walls. The treatment of *tubercles mesenterica* mainly consists in the administration of cod-liver oil, and the same dietetic and hygienic management as in any other form of phthisis. Stimulating liniments and iodine

ointment over the abdomen are serviceable, and the comfort of the child is much promoted by wearing a well adapted flannel bandage over the abdomen by night and day. See M. M. Rilliet and Barthez, *Traité des Maladies des Enfants* (Par. 1853); Dr. West, *Diseases of Infancy and Childhood* (Lond. 1865).

Mesh'id or Mash'ad, the capital of the province of Khorassan, Persia, on the Tehjind, 472 miles E. of Teheran, and 201 N. W. of Herat. It is surrounded by mud walls, 4 miles in circuit, and pierced by five gates, and is bisected by the Khiaban, a magnificent boulevard, shaded by fine plane trees. In its centre is a large open space, 160 by 75 yards, paved with grave-stones, surrounded by double storied cloisters, fronted with mosaic work, and entered by high arched gateways of exquisite architecture, faced with blue enamelled tiles, covered with gold and white inscriptions. On one side is the great shrine of M., the famous mosque of Imaum Reza, with its gilded dome and beautiful minarets, erected by Shah Abbas. Possessing the Imaum's tomb, M. is the Mecca of Persia, the great seat of the Shiites, and has several colleges, twenty-two caravanserais, and manufactures of silk velvets, coloured kerchiefs, satins, cotton checks, steel for the famous watered sword-blades, shagreen, &c. There is a great trade in shawls, fine silks, sugar, spices, indigo, tobacco, opium, saffron, lacquer-work, &c. Pop. 100,000, a large proportion of whom are Syads or 'holy men.'

Mesmer, Franz, was born at Itzmang, on the Lake of Constance, 23d May 1733, graduated M.D. at the University of Vienna in 1766, and published in the same year a dissertation upon the influence of the planets on the human body. About 1772 he began, along with Father Hell, a Jesuit, to investigate the effect of the loadstone upon disease; but as the former, in a book upon the subject, described M. as a mere assistant, a great controversy arose. The result was that M., being voted an impostor, began to travel, and in 1778 arrived at Paris, where he practised with great success the new treatment by mesmerisation. The French Government offered him a competency if he would permit a scientific committee to report upon his cures, but he declined, and afterwards travelled in England. He died in obscurity at Meersburg, in Swabia, March 5, 1815.

Mesmerism is the name given to the influence which certain individuals can exert upon others, so that the latter become unconscious, and more or less dependent upon the will of the former. Mesmer attributed this influence to a peculiar kind of *animal magnetism*. This name, however, is vague and misleading, for the phenomena seem to be due simply to a mental condition induced in the victim—a state somewhat similar to that of waking sleep. In both cases an external occurrence produces in the mind an idea, or succession of ideas, which in the one case results in a determinate action or speech, in the other in a dream. See ANIMAL MAGNETISM.

Mesne is the English law term for *intermediate*. 'It is applied to any incidental issue, or process of execution, between the beginning and end of a lawsuit. M. Profits are the rents drawn from real property by one wrongfully in possession of it.

Mesopotamia (Gr. *mesos*, 'middle,' and *potamos*, 'a river'), an extensive district in Western Asia, named from its position between the Euphrates and Tigris. It is mentioned as a kingdom in the Bible under three names, one of which, 'Aram Naharaim' ('Syria of the Two Waters,' Gen. xxiv. 10), is only translated in the Gr., which did not come into use probably till after Alexander's invasion of the E. Almost surrounded by the two great rivers, the country is fairly described by the modern Arabic name, *El Jazirah*, 'the island.' The inhabitants, mostly Arabs, Kurds, and Syrians, live by cattle rearing and trading. Cultivation has greatly lapsed under Turkish rule.

Mesozoic (Gr. 'middle-life'), or **Secondary Period**, in Geology, comprises the Trias, the Lias, the Oolitic or Jurassic, and the Cretaceous formations, and is distinguished as much from the Palæozoic as from the Kaiuozoic by its fossils. See the special headings.

Mess, Military or Naval. Every officer in the army subscribes thirty days' pay of his grade to the mess of the regiment to which he is appointed, as well as an annual payment of twenty days' pay to the band and mess, besides a monthly charge

for servants and sundries. Officers absent on duty are exempt from this latter charge, and married officers usually pay half the monthly charge, and can breakfast, dine, or lunch when they desire to do so. No officer is compelled to take any meal at his mess, but he must pay for the dinner whether he partakes of it or not, and a continuous avoidance of the mess dinner is not allowed. A grant of £25 per annum per company is made by Government to the mess expenses, and is called the Regent's allowance, having been instituted by the Prince Regent. Regimental messes vary much in their rules and bye-laws. On active service in the field the officers' mess is usually broken up, but not so in the case of the rank and file. Serjeants have a mess to themselves. Corporals and privates mess together, and a sum in proportion to the number of days they are in mess is deducted each month from their pay. The mess expenses in the navy are limited to £3 per month in the ward-room, where the superior officers mess, and £1, 10s. in the gun-room, which is used by junior officers.

Mess'ages and Mess'engers. Messages in a parliamentary sense are of three kinds. 1. From the Crown to either House of Parliament. 2. From the Commons to the Lords. 3. From the Lords to the Commons. Messengers, Kings' or Queen's, are officers employed by secretaries of state to carry despatches.

Messengers-at-Arms are legal officers employed by the Scotch Courts of Session and of Justiciary to execute a Summons (q. v.), or Letter of Diligence (q. v.), civil or criminal. They are appointed by the Lyon King-at-Arms (q. v.), and are under his control.

Messall'ina, Valeria, daughter of Marcus Valerius Messalla Barbatus, and of Domitia Lepida, granddaughter of Mark Antony. In A.D. 38, when only sixteen years of age, she became the third spouse of Claudius, who three years later was made Emperor. Her career—if we may trust the story of Tacitus and the verse of Juvenal—was one of unparalleled infamy and crime. To a licentiousness that knew no restraints, she added a cruelty that was without remorse. The daughters of Germanicus and Drusus, Appius Silanus, Valerius Asiaticus, M. Vinicius, Justus Catonius, and many others perished—the victims of her hate, her jealousy, or her fears. In A.D. 48, when only twenty-six years of age, she was put to death by command of the Emperor, who was persuaded that she aimed at his destruction. M. is perhaps the most appalling example on record of the vice and corruption of pagan Rome.

Messēnia anciently formed the S.W. part of the Peloponnesus, and was separated on the E. from Laconia or Sparta by the range of Taygetus, on the N. from Elis and Arcadia by the Phigalian chain and the deep ravine through which the Neda flows, while on the S. and W. it was washed by the Ionian Sea, which ran far into the land, forming the Gulf of Messene (mod. *Gulf of Koron*). In the centre of the country rose abruptly Mount Ithome (mod. Vuscano) from the earliest times the centre of the religion and polity of the region. But most of M. was level, and its plains were famous for their wheat harvests. The chief stream was the Pamisus, flowing S. from the borders of Arcadia into the Gulf of Messene, and receiving numerous affluents; the chief cities were Messene, Methone, and Pylos. Historically M. is celebrated for three wars with Sparta—the first (according to the common chronology) in B.C. 743–724 when the sacred fortress of Ithome was taken; the second in 685–668, when disaster again overtook the Messenians, and many emigrated to Zancle (see MESSINA); the third, in 464–454, which resulted in M. being annexed to Sparta. Epaminondas restored its independence in 369; but in 146 M. shared the general fate of Hellas, falling under the power of Rome. M. forms a *nomarchy* of the modern kingdom of Greece (q. v.).

Messai'ah (Heb. 'anointed'). It has been said that what distinguished the Jewish religion, at least in the latest centuries before Christ, from that of other nations of antiquity, was not merely monotheism, but even more, faith in the future. While among other nations men looked fondly back to a golden age irrecoverably lost, the Israelites persisted in turning their eyes in the opposite direction, and became all the more firmly attached to the idea of a coming period of virtue and happiness that the existing situation seemed to give the lie to their hopes. This period was to be ushered in by a great Restorer of the people of

God and the world in general, who was known as the M., the Anointed of the Lord, (i.e., the King), the king of Israel (Matt. ii. 4, xxiv. 23, xxvii. 37; Mark xv. 32; Luke iii. 15, xix. 38, xxiii. 2; John i. 41, 49), or simply He who was to come (Luke vii. 19). Leaving out of account the disputed passages in the Pentateuch (Gen. iii. 15, ix. 26, xii. 2, 3, xlix. 10; Num. xxiv. 17–19; Deut. xviii. 18, and others relating to 'the angel of the Lord'), which, whether they actually refer to the M. or not, contain nothing definite about his nature, the idea as it appears first among the prophets is indefinite, and does not necessarily include a person.

With the prophet Joel it is a longing for better times, while some consider the *Servant* of Jehovah, in the later part of Isaiah, to be the ideal, true Israel, who, although righteous themselves, had to suffer as a part of the nation, and bear the iniquity of the nation (cf. xli. 8, xlv. 1, 2, 21, xlv. 4, xlviii. 20, xlix. 1–7, liii.).

—2. The next phase of the idea is connected with a personal M., a prince of the house of David, 'introducing a new and glorious era of righteousness, reigning triumphantly on the throne of his ancestors, and exalting the nation to universal sovereignty,' a phase which appears especially in the Psalms and in Isaiah and Micah.—3. With the later prophets, about the time of the Captivity, the idea relapses to its original, general form.—4. A fourth phase appears in the Book of Daniel, namely, that the M. was something above man (cf. vii. 13). The belief that the M. had been taken up to heaven, from which he would return, was entertained by this time, and although he is still human in the Book of Daniel (the Son of Man, vii. 13), there is this new trait introduced, which leads to a higher conception. A further development in this direction is found in the Book of Enoch (q. v.) about 100 B.C., in which he appears as the appointed judge of the living and the dead, of men and angels, as chosen and concealed before the creation of the world, and sitting on the throne of the divine majesty as the representative of God, receiving the title of the Son of God. At the time of Christ the ideas regarding the M. had assumed a threefold form:—

1. The ordinary prophetic and Talmudic form, that he was to be a prince of the house of David, the conqueror of the Gentiles, and the righteous ruler both of Jews and Gentiles; 2. That he was to be a great prophet like unto Moses, according to Deut. xviii. 15; and 3. The form which appears in the Books of Daniel and Enoch, that he was heavenly as well as human, the Son of God (Matt. xxvi. 63). It is maintained by some and disputed by others, that the further idea of a *suffering* M. was familiar, or at least not unknown to the Jews at the time of Christ, an opinion which is founded on such passages as Psalms xxii., xlii., lix.; Isaiah liii.; Dan. ix. 24–27; Zech. xi.–xiii.; Luke ii. 35; John i. 29. The precise time when the M. was to appear was a mystery (Matt. xxiv. 3; Luke xvii. 20), but was determined so far that its approach was to be indicated by certain signs. The first of these was an increase of corruption and of the consequent calamities of all kinds: wars, famines, pestilences, earthquakes, fearful sights, and great signs from heaven (Matt. xxiv. 3–31). In short, the coming of M. was to be preceded by that of Antichrist, a being uniting in himself all the tendencies hostile to God, and thus provoking heaven to a manifestation of omnipotence (1 John ii. 8). The more immediate signs were, first, the appearance of an extraordinary star (Matt. ii. 2), and then of Elijah, of Moses, or Jeremiah, or of some one of the Old Testament prophets, come back to earth to announce the advent of the M. (Mal. iii. 1, iv. 5; Sir. xlviii. 10; 2 Macc. xv. 13; Matt. xvi. 14, xviii. 3, 10). The object of the coming of the M. was to establish 'the kingdom of God,' which meant a political, moral, and religious restoration of Israel, including deliverance from the Roman yoke (Judg. xvi. 17; Sir. i. 24; Luke i. 67, ii. 38), the recall of all Jews scattered abroad (Tob. xiii. 10, xiv. 5; 2 Macc. ii. 18), and the re-establishment of the throne of David (Acts i. 6), the restoration of God's favour to the Jews in consequence of the punishment of the wicked and the sufferings of the people, and the conversion of the Gentiles (1 Macc. iii. 8; 2 Macc. vii. 38, viii. 5; Tob. xiv. 6; Luke i. 74). At the actual appearing of the M., on a signal with a trumpet given by the attendant angels, the dead were to rise from their graves and present themselves for judgment (Dan. xii. 2, 3; 2 Macc. vii. 23–36). A glorious transformation was to pass upon the earth to fit it to be the abode of 'the elect,' and an everlasting kingdom to be established, with its centre at the New Jerusalem (Tob. xiii.; cf. Rev. xxi.).

Such were the Jewish notions regarding the M. at the time of Christ, and it is not difficult to understand why his disciples found such a contradiction and difficulty in the idea, and afterwards in the fact of his death (Matt. xvi. 22; Mark viii. 32, ix. 32; Luke ix. 45, xviii. 34), or why the Jews as a nation failed to see in him their expected M. The idea of a kingdom of God which was *not of this world* (John xviii. 36) was entirely new to them, and they have not yet come to see that the kingdom of God, purely spiritual and universal, which Jesus the Christ established, is more glorious than the one they had been expecting and are expecting still. See Reuss' *Histoire de la Théologie Chrétienne* (3d ed. Strasb. 1864).

Messina, the chief commercial city of Sicily, and chief town of the province of the same name, situated on the Strait of M., nearly opposite Reggio, and 59½ miles N.N.E. of Catania by rail. The seat of an archbishop, a university, and an appeal court, it is a stately modern city, with many spacious squares, has one of the finest harbours in the world, and lies at the foot of a jagged mountain range. The harbour is formed by a crescent-shaped peninsula (hence its old Gr. name *Zancle*, 'a sickle'), and strongly defended by a citadel and several forts. The chief buildings are the cathedral (begun 1098, partly rebuilt in 1865), with a richly decorated interior, the university, containing valuable art collections, and a handsome custom-house, opened in 1876. In 1875 the exports—olive oil, rice, lemons, wine, silk, and sulphur, amounted to £1,678,635; the imports to £1,429,371. There entered the port 4350 vessels of 1,282,177 tons, including 3083 steamers of 381,376 tons. Pop. (1874) 70,307. About 493 B.C. fugitives from Samos and Miletus took possession of the defenceless Zancle, and soon afterwards they were followed by great numbers of Messenians, who gave to the city the name of Messina. It suffered greatly during the Punic wars, and was taken by the Saracens in 842 A.D. The massacre known as the Sicilian Vespers took place here in 1282. In the 16th c. Pelidoro da Caravaggio founded a celebrated school of painting at M. The town was almost destroyed by an earthquake in 1783.

The Strait of M. (It. *Faro di M.*, 'Ferry of M.,' Lat. *Mæmerinum fretum*) separates Italy from Sicily, and connects the Ionian and Tyrrhenian seas, is 26 miles long, from 2 to 12 broad, and of great depth. The tide is very irregular, and the ebb and flow succeed each other rapidly. The curious phenomenon *Fata Morgana* (q. v.) is witnessed here. See also SCYLLA and CHARYBDIS.

Mess'age, in English law, denotes a dwelling-house with or without land annexed.

Metalliferous Mines, Regulations Act. This Act applies to every mine to which the Coal Mines Regulations Act does not apply (see COAL MINES, LAW AS TO). No boy under twelve years of age, and no female of any age, is to be employed below ground. The hours of employment of boys under sixteen years of age are the same as in coal mines, and the boys are under the same regulations.

Metallurgy is the act of extracting metals from their various ores. The processes employed are partly mechanical and partly chemical, and the details of treatment differ in many particulars for the different metals. There are, however, several essential features common to the entire range of metals, and while referring for details of each to their own proper headings, the operations they undergo in common may be here briefly alluded to. Metals occur in nature either native, or in the form of ores. Gold and platinum are the only two metals found exclusively in the native or metallic condition; but sometimes copper, silver, mercury, and bismuth are also obtained native. Ores are compounds of metals with other chemical elements, the chief of which are sulphur forming sulphides, oxygen whence are the oxides, carbonic acid yielding the carbonates, and chlorine which gives rise to the chlorides. Many ores again contain two or more metals, and these in such proportion that it is profitable to extract and reduce both or all the metallic constituents. Ores are rarely extracted from the mine in a state of purity; but usually they are associated and intermixed with earthy or rocky matter; and to free them as far as possible from these impurities they are first dressed by reducing them to a convenient size, and separating the purer pieces

from the more earthy by hand picking. The separation of the comparatively pure and consequently heavy ore from the impure is frequently effected by the stamping and dressing mills worked in connection with running water, which accurately arranges and separates the crushed ore according to its specific gravity. The process of washing is also employed to enrich and improve crushed ores by removing the earthy matters associated with them. In most cases previous to smelting, the ores have to undergo the operation of calcination or exposure to a high temperature with the air excluded, or of roasting, in which the material is similarly treated with access to air. By calcination, moisture, carbonic acid, and bituminous ingredients are driven off; in roasting, sulphur and other volatile constituents are vaporised, and the metal is left combined with oxygen. In the process of smelting which follows, the prepared ore is mixed with a flux substance for promoting the fluidity of the metal, and at the same time for aiding in its reduction from the compound in which it exists. The smelting takes place in crucibles or in furnaces of various construction, according to the nature or quantities of the materials operated on, and the 'heat of reduction' of course varies enormously for the different metals. The products are the metal in a more or less pure condition, and slag—a glassy compound of the impurities associated with the ore and the fluxing materials employed in its reduction. The wet process or hydro-metallurgy now employs an important part in the production of Copper (q. v.).

Metals. See ELEMENTS, CHEMICAL.

Metals, in Heraldry, are either *or* ('gold'), or *argent* ('silver'). The former is represented in engravings by dots, the latter by a plain surface.

Metamorphic Rocks (from Gr. *meta* and *morphē*, 'change of form') are rocks which, though undoubtedly of aqueous origin, have through the action of heat or pressure become quite altered in character, so as to lose all or nearly all trace of their original structure. Those in which the structure is still visible may be grouped in three classes—arenaceous, argillaceous, and calcareous. To the first belong grauwacke and quartzite, both altered sandstones. The various kinds of clay, indicating by their planes of cleavage the direction of the pressure which metamorphosed them, belong to the second group; and marble, dolomite, serpentine, and various porphyries are included in the third. More metamorphosed than these, but still showing in their foliations their original stratification, are the so-called schistose rocks—mica-schist, gneiss, chlorite-schist, hornblende-schist, &c. The last group of M. R. includes those which have lost all trace of original structure—such as granite, syenite, diallage-rock, &c. Many of these are not distinguishable from true igneous rocks which have cooled from a molten condition; and indeed, just as there is a gradual transition from simple stratified rocks through contorted strata to M. R., so there is a gradual transition from the latter to igneous rocks. These again are slowly weathered away, and their particles are carried off suspended in water, and are deposited on the bed of some lake or ocean, where they collect in time, and form a new series of aqueous formations.

Metamorphosis (Gr. *meta* and *morphōsis*, 'the act of changing form'), in Mythology, denotes the 'transformation' of human beings into beasts, trees, stones, fire, water, &c., fabled in countless legends of the Greeks, Romans, Teutons, and other Aryan peoples. The mysterious changes of outward nature doubtless first dictated a belief which was widened by the popular acceptance of poetic imagery as actual fact, and by the tendency of superstition to assign the inexplicable to the supernatural. Eastern poets employed it much in moral allegory, and this use of M. is frequent in such Greek writers of the Alexandrian age as Callisthenes, Antigonos, Nicander, and Parthenius. The metamorphoses of Greek mythology proved a rich storehouse for the poetry of Ovidius (q. v.), as in later times did those of the old German magic and fairy tales to Wieland and Herder. Traces of the old were-wolf, swan-maiden, and vampire superstitions linger on in the belief—still current in some out-of-the-way corners of England—that a witch has power to transform herself into a hare or other animal.

Metamorphosis of Animals, the name given to the changes of greater or lesser extent which many animals undergo

in passing from the egg to the mature and adult state. Strictly speaking, every animal may be said to undergo M. in the course of its development. The development of a chick within the egg is a series of changes of very marked and definite nature, and which result in the production of a new being. But the term M. must rather be held as applying to those phases of *Development* (q. v.) which are exhibited outside the egg, and in the course of which the young animal shows phases of existence of a kind or nature often widely different from those seen in its adult state. The egg of a butterfly, of a fly, or of a beetle, gives origin to a *caterpillar* or *larva*, which after passing its existence in the work of nutrition, next assumes a quiescent state, and becomes the resting *chrysalis* or *pupa*, within the body of which the lines of the future animal are, as it were, laid down, and from the elements of which—accumulated in the larval state—the adult insect or *imago* is finally formed. The young frog, toad, or newt, again, leaves the egg in the form of a tadpole. Gradually acquiring outside gills, it lives an aquatic life. Next, the outside gills become internal, and the limbs are duly developed. In the last place lungs are produced, and in the frog and toad, the tail of the tadpole state becomes abortive in the adult, which also gets rid of its gills, and breathes throughout its after-life by means of lungs alone. Similarly, the young crab, barnacle, and the young of many other *Crustacea* (q. v.) leave the egg as little free-swimming beings, each known as a *nauplius*, and through the M. of this nauplius-larva the perfect forms are sooner or later evolved.

That modifications of development have taken and still take place, is proved by the fact that recently the *Axolotl* (q. v.) of Mexico has been experimentally metamorphosed into the *Ambylostoma*, a N. American eel, by careful attention in inducing the axolotl to leave the water and to gradually adapt itself to a land existence. If, therefore, modifications may take place even in the structure of the adult animal, during development, and in the process of early growth, such modifying processes may be regarded as having operated in the past in inducing and perfecting M. To quote Mr. Darwin's words, which apply very well to the whole question of M. and development: 'Embryology rises greatly in interest, when we look at the embryo as a picture, more or less obscured, of the progenitor, either in its adult or larval state, of all the members of the same great class;' and again, 'community in embryonic structure reveals community of descent.'

M. of Organs, in Botany.—Goethe was the first to propound the theory, though somewhat poetically, that all the organs of the higher plants can be referred back to a single, or, at least, to a very small number of fundamental forms; that, in fact, every organ is either axial (stem), or foliar (leaf), or is compounded of these two. That this is actually the case is shown, not only by the history of development, but also by close investigation of those abnormal processes which are called M. According to Goethe, a foliar organ must be considered the more highly developed the higher it stands on the axis of the plant, the nearer therefore it is to the centre of the flower; and an ascending series can be constructed as follows:—leaf, bract, sepal, petal, stamen, carpel. The M. may be either progressive or retrogressive, according as the transformation of the foliar organ takes place in the direction of a higher or a lower member of the series. Instances of *retrogressive M.* are commonly furnished by the rose, where the sepals are transformed into bracts or leaves; the tulip, where the three carpels and six stamens become petaloid; and the white water-lily (*Nymphæa*), where we can plainly trace the chain of transition from stamens to petals. Double flowers are produced in like manner, and as a necessary consequence are sterile. When the retrogressive M. goes back still further than the doubling of the flower, the parts become green and leaf-like, as is not uncommon in clover and other Leguminosæ. Instances of *progressive M.* are rarer, though a number have been recorded. It is not, for example, uncommon to find the shepherd's purse (*Capsella*), instead of bearing four petals and six stamens, having ten stamens, and the same has been noticed with the wall-flower. Sometimes also in willows the stamens are changed into carpels, and bear ovules, rendering a naturally dioecious plant apparently monœcious.

Metaphor (Gr. *metaphora*, 'a transference') is that trope which substitutes one name for another, because of a real or

imagined likeness between the objects. It may substitute the animate for the inanimate, the inanimate for the inanimate, the animate for the inanimate, or the inanimate for the animate. Examples:—'Cato barked at Scipio,' 'A sea of glass,' 'Mother Earth,' 'the Iron Duke.' A common fault of style is mixed or incongruous M.; as, 'The evils flowing from such a view have their root,' &c. Addison's rule for its avoidance is that the M. should be fancied as painted on canvas.

Metaphysics, a term of uncertain origin, first occurs as the title of that part of Aristotle's writings which concerns itself with the highest speculative ideas, and may have been given to this as coming after the books on physics (*meta ta physika*). The word was rarely used by the ancients, but has established itself in modern times as the name of the science which treats of the mind, and its relations to the phenomenal universe. It embraces Ontology (q. v.), or the theory of being, and Psychology (q. v.), or the analysis of the properties and laws of the mind. Physicists somewhat scornfully refuse to M. the name of a science, on the ground that no positive knowledge has been secured by all the laborious disquisitions that have been written on the subject since the days of Aristotle.

Metastasio, Pie'tro (properly **Pietro Trapazzi**), son of a common soldier, was born at Rome, January 3, 1698. The jurist Gravina, observing the boy one day on the street amusing his schoolfellows by improvising verses, became interested in him, and educated him for the law. When twelve he translated the *Iliad* into *ottava rima*; and at fourteen he composed the tragedy of *Giustino*. At Naples, Brugnattelli the actress admitted him to her establishment, and to her influence M. attributed much of his success in writing for the stage. Early abandoning classical drama, M. strove to bring to the aid of opera all that was capable of musical illustration. His plots are often absurd, but his characters are strongly marked and contrasted; his lyrics are exquisite, and very frequent—for it was his habit to cut short recitative; and over all he cast a glamour of romance and spirituality which blended with the charms of music enchantingly. In Italy he wrote *Endimione* (1721), *Gli Orti Esmeraldi*, and *Angelica* (1722), *Didone abbandonata* (1724), *Catone in Utica* (tragedy, 1728), *Ezio, Alessandro nell'Indie*, *Semiramide*, and *Artaserse* soon after. He went to Vienna in 1730 as imperial poet, and there produced *Adriano in Siria*, *Demetrio* (1731), *Issipili* (1732), *Giuseppe*, *Demofonte*, and the *Divine Olimpiade* (1733), *La Clemenza di Tito* (1734), *Achille in Sciro* (1736), *Ipermestra*, *Temistocle* (1738). M. died at Vienna, 12th April 1782. There are numerous editions of his works, among which may be noted those of Paris (12 vols. 1782), Parma (20 vols. 1820), and Florence (6 vols. 1819-23). See Bunney's *Annals of M.'s Life* (Lond. 1796).

Meta'yer is the term used in France for a labourer or peasant who receives an allotment of land from his proprietor, and pays his rent in a certain amount of the produce which remains after a deduction has already been made to keep up the stock. The word is derived from the Lat. *mediatarius*, found in Med. Lat. documents, 'one who pays half,' i.e., of his produce. The terms of contract vary in different countries, but the lease itself passes down from family to family. M. cultivation has been comparatively unsuccessful in France, but, according to the testimony of Châteauneux and Sismondi, it has been accompanied with the best results in Italy. Its weak points consist in the absence of motive towards the severest exertions, inasmuch as half at least of the produce is alienated from the M., and in the unlikelihood of the cultivators laying out their savings upon the further improvement of the land. Where it flourishes it is said to operate in favour of connubial prudence, and other virtues of an estimable order. See Sismondi, *Nouveaux Principes d'Économie* (book iii. chap. v.), and J. S. Mill's *Principles of Political Economy*.

Met'calfe, Sir Charles (afterwards **Lord**), a distinguished Indian civilian, was the son of a successful Bengal officer, and was born at Calcutta, 30th January 1785. He was educated at Eton, and arrived in India as a writer at the age of fifteen. He was early selected for the political (or diplomatic) department, and in 1808 was sent on the first British embassy to Runjeet Singh, the Sikh Rajah. M. was afterwards Resident at Delhi and Hyderabad, and Member of Council at Calcutta. In 1835-36 he acted as Governor-General of India, and signalled himself by removing

all restrictions on the press of that country. He was the first Lieutenant-Governor of the newly-formed N.W. Provinces. On his return to England M. was appointed Governor of Jamaica (1839-41), and subsequently Governor-General of Canada (1843-45). In both colonies he acted with great moderation in troublous times. He was raised to the peerage in 1845, and died at Malshanger, near Basingstoke, 12th September. See Sir J. W. Kaye's *Lives of Indian Officers* (Lond. 1867).

Metempsychosis is a Greek word denoting the transferring of the soul from one body to another. See TRANSMIGRATION OF SOULS.

Meteoritic Iron, the metal of which the great mass of Aërolites (q. v.) are composed, is an alloy of iron with nickel and cobalt. The iron meteorites often contain nodules of iron, phosphoret of iron, and nickel and graphite. When polished, the surface is very brilliant, but it usually rusts quickly from the presence of chlorine.

Meteorology is the science which treats of atmospheric phenomena, of their causes and effects. Among the ancients, except by the collection of weather portents, M. could make but little progress, since the indispensable instruments of meteorological research, the barometer and thermometer, were unknown. The invention of these instruments forms an epoch in the history of the science, and since then the development has been gradual but continuous. At the present day, it is true, there are doubts as to whether M. can be truly reckoned a science, there being comparatively so little of the certainty and accuracy that mark other sciences. There can, however, be no doubt that the principles upon which M. depends are being rapidly discovered and applied. The reason of the slow development of meteorological science is that it is not strictly an experimental science. The investigator cannot order nature as he likes, but must accept things as they come. It is thus somewhat similar to astronomy, except that there are many more causes at work whose resultant effect, even if these causes themselves were fully known, is therefore the more difficult to understand. The chief source of all our climatic variations is the solar heat and light, combined with the earth's rotation, the configuration of land and water, and the action of the moon. Further, the sun appears to exert other influences than are attributable to mere thermal action. The established connection between sun-spots and magnetic storms, and between sun-spots and periods of rain and drought, is a discovery which cannot but lead to wider views of the whole economy of nature. For a proper study of M., observations are necessary, and when these are established distinct from the astronomical observatories we may expect the rapid development of the science in all its branches. To such articles as ATMOSPHERE, CLIMATE, CLOUDS, JARRENS, HYGROMETER, WINDS, &c., the reader is referred for the ordinary facts of M. The best general treatise on M. is that of Kaemtz; while the writings of Dove, Colding, Bravais, Glaisher, Forbes, Buchan, and others on special parts of the subject are of great value.

Me'teors. See AEROLITES.

Methodists is the name which was given in banter by their fellow-students at Oxford to John Wesley (q. v.), his brother Charles, and the other young men who in 1727 organised themselves into a brotherhood for the study of the Bible, visiting the poor, observing Wednesday and Friday fasts, &c., or, in short, for the promotion of personal piety according to the principles and practice of the Church of England. In 1735 this brotherhood consisted of about fifteen members, including J. and C. Wesley, Whitfield, Hervey, Ingham, Clayton, and Broughton; and after Wesley's return from Georgia in 1738 the movement was revived in London on similar principles. Wesley's views at this time underwent a great change. In Georgia he had been a High Churchman, but having now experienced what he considered his real conversion, the corner-stone of his creed was now the Doctrine of Assurance. Under the impression that he was excluded from the churches of the land, he took to preaching in the fields, and in unauthorised places of worship, and began to employ lay agents as assistants to his ministry. He had no intention of separating himself from the Church of England, indeed, repudiated that idea to the last, but he had now accepted the principle 'that the order of that Church was to be put aside whenever the spiritual interests to which it was

justly subservient could be best promoted by its neglect.' He was partly influenced in this by his intimacy with the Moravians (q. v.), but it was only another step in the direction of forming a religious association over which he might have complete control when he separated himself from that body; the separation removed one of the main barriers in the way of the course of unfettered personal action on which he now entered. It tended still further to alienate Wesley and his followers from the Church, and give them the constitution of a separate sect, when in 1784 he assumed the office of a bishop and consecrated certain clergymen as bishops ('superintendents,' as he called them) and presbyters ('elders'), and when in 1786 he authorised his preachers to use the Book of Common Prayer in their services. At Wesley's death in 1791 the society he had founded extended throughout the whole of England and Wales and across the Atlantic; and as soon as his personal influence, on which the whole organisation was dependent, was withdrawn, it became apparent that he had really founded a sect. Dissension immediately sprang up regarding (1) the management of the society, and (2) the administration of the sacraments independently of the Church; there being three parties, which might be described as a Church party, a dissenting party, and an intermediate or Wesleyan party. The middle party had the most influence, and the questions in dispute were settled in 1795, when eighteen 'Articles of Pacification' respecting the sacraments and discipline were drawn up. According to these articles the sacraments of Baptism and the Lord's Supper were only to be administered in Methodist chapels by the consent of the Conference, but it was not long till the practice became almost universal.

Almost the only events of importance in the later history of the M. consist of the formation of new sects. The principal of these are the following:—'New Connection' or 'Kilhamites,' who succeeded in 1797 under the leadership of A. Kilham, because their preachers were not allowed to administer the sacraments, and laymen were excluded from the Conference. They are chiefly found in the northern counties of England, numbering, in 1870, 22,633 members. The Welsh Calvinistic M. owe their origin to Howell Harris, an Oxford disciple of the Wesleys, and friend of Whitfield. When he began itinerant preaching in Wales in 1736, he followed the latter in his Calvinistic theology, and the former in his organisation. The organisation of the sect was completed in 1811 by T. Charles of Bala. In 1823 they adopted a Confession of Faith founded on the Westminster Confession. The sect numbers at present about 60,000, with 200 ministers and 250 lay preachers. The Primitive M. owe their origin to L. Dow, an American, who introduced into England the institution of 'camp meetings,' and was supported by two local preachers, Clowes and Bourne, who desired by 'revival services' to gain converts to the sect by the same kind of excitement as Wesley and Whitfield had aroused. Bourne and Clowes, being expelled from the main body in 1808 and 1810 respectively, at once founded a new sect, which in 1870 numbered in England 150,169, and elsewhere 12,000, with 961 ministers, and 14,332 lay preachers. The Bryanite M. or 'Bible Christians' owe their origin to a local preacher of Cornwall named O'Bryan, who separated from the Wesleyan M. in 1815. Almost the only difference between the Bryanite M. and the latter is that they allow women to preach, and have a larger proportion of the lay element in their organisation. In 1870 they numbered 18,466. The Wesleyan M. Association was founded in consequence of the expulsion of Dr. S. Warren from the M. body by the Conference of 1835, for the part he had taken in the dispute about the establishment of the Wesleyan Theological Institution. Within two years he was joined by about 20,000 others, who formed themselves into the new sect of Associated M. Another sect called the Wesleyan Methodist Reformers was formed by the excommunication of a large number of M. who had ventured to criticise the conduct of the Conference from 1844 to 1848. In 1857 these last two bodies formed themselves into a new sect called the United Methodist Free Churches, which in 1870 numbered in England 62,898 members, with 5786 on trial, and 5000 elsewhere.

In America the leading sect of M. has an episcopal constitution. Whitfield had gone thither in 1738, after Wesley's lamentable failure in Georgia, but the first Methodist congregation was formed by some Irish emigrants in New York, in 1766. The sect, which in 1783 numbered 14,000 members,

with 43 preachers, received a constitution from Wesley in 1784. He sent out to them Dr. Coke and Mr. Asbury, whom he had ordained as 'superintendents,' enjoined upon them the use of his abridged Book of Common Prayer, and gave them Twenty-Five Articles of Religion. This Episcopal constitution of bishops, elders, and deacons, with the general organisation of the English M., the sect has ever since retained under the name of the Methodist Episcopal Church, numbering in the United States about 1,250,000, with about 17,000 preachers. A sect called the Methodist Reformed Church separated from the main body in 1814, repudiating episcopacy and slavery. Although augmented by another secession from the Methodist Episcopal Church in 1843, they only number yet about 25,000, with about 600 preachers.

Organisation.—The systematic form of Methodism, which consisted at first merely of 'a machinery for keeping together those people who adhered to the ministry of John and Charles Wesley,' was adopted in 1742, and in 1743 the Society rules which are still in force were drawn up. The present organisation is as follows:—(1) *The classes*, to one of which every Methodist must belong, and several of which make a 'society' or congregation, consist of from twelve to thirty persons, who meet once a week, and after praise and prayer, follow the leader of the class in detailing their spiritual 'experience' during the past week. Besides this object, however, the class has an important connection with the finances of the community, since each member has to contribute at least one penny weekly and one shilling quarterly to the general fund, out of which the ministers are paid. (2) A *circuit* comprehends generally the chapels in a town, and the villages round. To each are appointed from one to five ministers, or 'travelling' preachers (so called because they are not allowed to continue in the same circuit for more than one or two years), and a number of lay or 'local' preachers. The senior minister has the general supervision of all the societies and preachers in a circuit, and is called the 'superintendent.' (3) *The districts*, of which there are thirty-three in England and Scotland, contain each on an average eighteen circuits. The preachers in a district meet at appointed times as a local committee of the Conference when it is not sitting. (4) *The Conference*, which consisted originally of certain travelling preachers invited by Wesley every year to meet him for consultation (the first time in 1744), but was properly constituted in 1784 by a Deed of Declaration to consist of 100 travelling preachers, meets once a year in London or other large town, its members now being all travelling preachers, who have acted as such for five years, and have been admitted into 'full connection.' (Originally the unit of Methodism was the *band*, which consisted of from five to ten persons, who met once a week for the purpose of confessing their sins to each other, and praying for each other. This institution, which was copied from the Moravians, fell off greatly after Wesley's death. Its purpose, so far as is thought to be practicable, is now served by the class.) The *theology* of the M. is formally that of the Church of England, as expressed in the Thirty-Nine Articles and the *Book of Common Prayer*, and expounded in Wesley's *Sermons and Notes to the New Testament*. Like all the Laudian school, to which Wesley belonged, he received the epithet of 'Arminian,' a title which he accepted in the sense of Anti-Calvinistic, in respect of the Calvinistic doctrines of a limited Atonement (q. v.), Election (q. v.), and Reprobation (q. v.). It was on these points that Whitfield and he had their controversy, and on which the Calvinistic M. differ from the Wesleyan M. See Southey, *The Life of J. Wesley and the Rise and Progress of Methodism* (Lond. 1820), Taylor, *Wesley and Methodism* (Lond. 1851), Smith, *History of Wesleyan Methodism* (Lond. 1857), Wesley's *Works*; *Minutes of Conference*; Tyerman's *Life and Times of Wesley* (1870); Urrin's *Wesley's Place*, &c. (1870); Blunt's *Dict. of Doct. and Hist. Theol.* (1872), and *Dict. of Sects*, &c. (1874).

Meth'yl, a hypothetical compound radical, homologous with Ethyl (q. v.). Its formula is CH_3 . Marsh Gas (q. v.) may be thus regarded as the hydride of M. Its other compounds are obtained from methylic alcohol or Pyromylic Spirit (q. v.), whose formula is $(\text{CH}_3)_2\text{HO}$. The most important are methylic ether or oxide of M. $[(\text{CH}_3)_2\text{O}]$, iodide of M. (CHI) , salicylate of M. or oil of winter green $(\text{CH}_3 \cdot \text{C}_7\text{H}_5\text{O}_2)$, and formiate of methyl $(\text{CH}_3 \cdot \text{CHO}_2)$. It forms also a sulphide bromide chloride cyanide, exactly as ethyl does (see HYDROCARBONS). If

the iodide be heated with zinc a gas having the composition CH_3 is obtained, so that in this point it differs from ethyl, which cannot be obtained in a separate state.

Methylated Spirit is spirit of wine with a little wood naphtha or methylic alcohol added, to prevent persons from drinking it. It is generally used in the preparation of varnish, and for preserving specimens in museums.

Metonic Cycle, the cycle of nineteen years, invented by Meton (430 B.C.), after the lapse of which the new moons fall on the same days and the eclipses occur in nearly the same order. The reason of the phenomenon is that nineteen years nearly correspond to 235 lunations.

Metonymy (Gr. *metonymia*, 'change of name') is the trope which substitutes one name for another on account of some actual association between the things, whether physical or historical, as when 'grey hairs' stands for 'old age,' 'blue jackets' for 'sailors,' or 'Bacchus' for 'wine.'

Metopé, in Doric architecture, the part of the frieze between two Triglyphs (q. v.). It was sometimes plain, sometimes carved in high relief, and was called M. (Lat. *columbarium* or *intertigium*) from its being 'between' (Gr. *meta*) the 'openings' (Gr. *opai*, Lat. *tignorum cubilia*) into which were fitted the ends of the beams supporting the roof.

Mètre is the rhythmical arrangement of syllables which distinguishes verse from prose. With the ancients M. was determined by quantity—the succession of long or short syllables; in modern poetry it is regulated by accent. Modern metres have commonly been associated with rhyme; and alliteration and assonance, though found in classical writers, became distinctive of the poetical measures of the Low German languages. The varieties of M. are treated separately in this work. For those of our own language, see Guest's *History of English Rhythms* (Lond. 1838), and Sylvester's *Laws of Verse* (Lond. 1870).

Metric System is the system of weights and measures which was introduced into France in the beginning of this c., and which is gradually finding its way into other countries. The basis of the system is the *mètre*, which was originally defined as the ten-millionth part of the quadrant of the meridian of Paris, but is practically, like our yard, determined by a standard length preserved in the archives of France. The unit of mass is the *gramme*, which is defined as the mass of a cubic centimetre of distilled water at its point of maximum density. The unit of capacity, the *litre*, is the 1000th part of a cubit metre, and the unit of surface, the *are*, is 100 square metres. The length of the metre in inches is 39.37079, and an inch is equal to 2.539954 centimetres. For the method of nomenclature of the multiples and submultiples of the units of this system, see DECIMAL SYSTEM.

Metronome, a box containing a pendulum moved by clock-work, for determining, or rather describing, the various *rates* of musical compositions.

Metropolitan, or chief bishop, is so entitled because consecrated in the metropolis of his province. The Metropolitans of the Church of England are the Archbishops of Canterbury and of York. A M. is *enthroned*; other bishops are *installed*.

Mett'ernich, the name of a noble German family, originally belonging to the Lower Rhine, which in the 16th and 17th centuries reckoned three ecclesiastical princes, two of Trier and one of Mainz. It branched off into several lines, of which that of M.-Winneburg is the most notable. To this belonged by far the most famous member of the family, Clemens Wenzel Nepomuk Lothar, Prince von M.-Winneburg, the son of Franz George Karl M., a diplomatist of mark. M. was born at Koblenz, 15th May 1773, educated at Strassburg and Mainz, and was attached to the Austrian embassy at the Hague in 1794. In 1795 he married the heiress of Kaunitz (q. v.), and at Rastadt he represented in Congress the Westphalian nobility, after which he proceeded to St. Petersburg. M. was minister at Dresden in 1801, ambassador at Berlin in 1804, and after Austerlitz and the Peace of Presburg he was accredited to the Court of Napoleon, where amidst much personal provocation he retained his dignity and good humour. He became Foreign Minister of Austria (1809), and planned the marriage of Napoleon with an archduchess, which ended in Maria-Louisa (q. v.) being conducted to Paris. This did not hinder Austria from taking advantage of

the check offered to France in Russia, and under M.'s policy war was declared (1813). On the field of Leipsic M. was made a prince of the empire. He presided at the Congress of Vienna, and inspired the reactionary policy of the Holy Alliance. For thirty years no man wielded greater influence on the Continent. At the revolution of 1848 he was driven from Vienna, and took refuge in England. Though he returned to Austria in 1851, his influence was practically gone. He died at Vienna, 11th June 1859. M. was one of those statesmen whom the French Revolution of 1789 had thoroughly alarmed, and who had formed the fatally erroneous notion that the people could never be trusted, that repressive measures were necessary to prevent social anarchy, and that the welfare of Europe could only be secured by the coalition of despots. His accomplishments in art, science, and letters, were of a high order. See Schmidt-Weissenfel, *Biography of M.* (2 vols. 1859-60).—His son, **Richard Clemens Lothar Hermann, Prince von M.**, born 7th January 1829, was Austrian ambassador at Paris 1859-71, and was a great favourite in French society.

Metz, the chief town and fortress of German Lothringen, lies in the wide basin of the Moselle, which sends off several arms through the town, and here receives its affluent the Seille, 35 miles N. of Nancy by rail. One of the greatest strongholds in Europe, it is now (1877) defended by eleven bastions and by seven forts placed on the surrounding heights. It is the seat of a bishop, and a civil and commercial tribunal, and has a magnificent Gothic cathedral of St. Stephen, begun in the 13th c. and consecrated in 1546 (restored 1830-35), with a fine tower 387 feet high, containing a bell of 13 tons. Other buildings and institutions are the churches of St. Vincent, dating from the 13th c., and St. Eucharis, from the 12th c., the handsome Palais de Justice, a college, a school of artillery, a museum of Roman antiquities, a library of 30,000 vols., a botanical garden, an arsenal, &c. A spacious esplanade is laid out with pleasant walks and flanked by extensive barracks. The manufactures are woollens, silk, embroideries, brushes, felt, leather, paper, iron and copper wares, drugs, &c., and there is a large trade in wine, timber, grain, and hides. Pop. (1875) 45,673, almost entirely French, and exclusive of a garrison of some 10,000. M., the *Divodurum* of the Romans, was the chief town of the Gallic *Mediomatrici*, from whom about the 5th c. the town received the corrupted name *Mettis*, hence the modern M. It was the capital of Austrasia, and passed to Germany on the partition of the Frankish empire. Treacherously seized in 1552 by the French, who held it against a siege by Karl V. from October 1552 to January 1553, it was formally acknowledged to be a French possession by the Peace of Westphalia, 1648. M. was greatly strengthened by Napoleon III., and its inglorious surrender (27th October 1870) was one of the main events in the Franco-Prussian War. A French army of 173,000 men, 6000 officers, and 3 marshals, became prisoners of war. The Germans acquired possession of war material worth £3,200,000, comprising 800 guns, furniture for 85 batteries, 66 mitrailleuses, 300,000 muskets, a vast quantity of sabres, cuirasses, &c. M. was ceded to the German empire by the Peace of Frankfurt, 10th May 1871. See Coster's *Geschichte von M.* (1871).

Méudon, a town of France in the department of Seine-et-Oise, 5 miles W. of Paris by rail, has stone-quarries and limekilns, and a château erected (1699) by Philibert Delorme for the Dauphin, and almost entirely destroyed by fire, January 30, 1871. Pop. (1872) 5101. Rahelais was curé of M. (1551-53), and here the besieged troops of Paris were repulsed in a sortie, January 13-14, 1871.

Meurthe-et-Moselle, a frontier department in the N.E. of France, formed, 11th September 1871, from the portions of Meurthe and Moselle remaining after the Peace of Frankfurt. Area, 2025 sq. miles; pop. (1872) 365,137. It is entered by spurs of the Vosges range, which bounds it on the E., and is watered by the Moselle and its affluents the M., Madon, Seille, &c. Much of the country is richly wooded, and the broad fertile valleys produce abundance of grain, wine, fruits, flax, colza, &c. There are valuable mines of rock-salt, and the manufactures are chiefly linens, muslins, lace, leather, paper, crystal, and iron wares. The chief town is Nancy.

Meuse, a department in the N.E. of France, occupying the angle between Luxemburg and Elsass-Lothringen. Area, 2405 sq. miles; pop. (1872) 284,725. It consists mainly of the

basin of the M. (see MAAS), enclosed by parallel ranges of hills, and is also watered by the Aire, Othain, Ornaine, and Saule. The products are timber, wheat, and wine of good quality, cattle, horses, sheep, and swine, and iron, limestone, gypsum, &c. The chief town is Bar-le-Duc.

Mexico or **Mejico** (Aztec. *Mexitli*, a name of the tutelary deity), a federal republic of N. America, after the United States and Brazil the richest and most populous country of the New World, is situated in lat. 15° 40'—32° 47' N. and long. 87° 4'—117° 8' W. Extending from the Gulf of M. and the Caribbean Sea on the W. to the Pacific Ocean on the E., and from the United States on the N. to Guatemala and Honduras on the S., it resembles a curved horn in outline, and is 1950 miles in extreme length and only 140 miles broad in the S. at the Isthmus of Tehuantepec, expanding as it stretches N. till it attains an extreme breadth, from the mouth of the Rio Grande to the W. coast of California, of 750 miles. The coast line, is more than 6000 miles long. The following are the areas and populations of the states, according to the *Diario Oficial* of 7th June 1875:—

States.	Area in sq. miles.	Pop. 1875.	Chief towns.
Aguas Calientes . . .	2,805	89,715	Aguas Calientes.
Campêche . . .	25,832	80,366	Campêche.
Chiapas . . .	16,048	193,987	San Cristoval.
Chihuahua . . .	83,746	180,618	Chihuahua.
Coahuila . . .	50,890	98,397	Saltillo.
Colima . . .	3,743	65,827	Colima.
Durango . . .	42,510	185,077	Durango.
Guanajuato . . .	11,411	900,000	Guanajuato.
Guerrero . . .	24,550	320,069	Bravos.
Hidalgo . . .	8,163	404,207	Pachuca.
Jalisco . . .	39,168	966,689	Guadalajara.
México . . .	7,818	663,557	Toluca.
Michoacan . . .	25,689	618,240	Morelia.
Morelos . . .	1,776	150,384	Cuernavaca.
Nuevo-Leon . . .	23,635	178,872	Monterrey.
Oaxaca . . .	33,591	648,779	Oaxaca.
Puebla . . .	12,021	697,788	Puebla.
Querétaro . . .	3,207	153,286	Querétaro.
San Luis Potosi . . .	27,500	460,122	San Luis Potosi.
Sinaloa . . .	36,198	168,031	Culiacan.
Sonora . . .	79,021	109,388	Ures.
Tabasco . . .	11,851	83,707	San Juan Bautista.
Tamaulipas . . .	30,225	140,000	Ciudad Victoria.
Tlaxcala . . .	1,620	121,663	Tlaxcala.
Vera Cruz . . .	26,232	504,950	Jalapa.
Yucatan . . .	49,567	422,305	Mérida.
Zacatecas . . .	22,998	397,945	Zacatecas.
Territory of California . . .	61,562	23,195	La Paz.
Federal District . . .	461	315,936	Mexico.
	743,948	9,343,480	

Of the total population rather more than one-half are pure Indians, while about a million are whites, 6000 negroes, and the rest mestizoes, zamboes, mulattoes, &c.

Physical Aspect.—The heart of the country, to the extent of three-fifths, is occupied by the plateau of Anahuac (*tierras frias*), which has an elevation of from 6000 to 8000 feet above the sea, and is skirted by semi-tropical terrace-lands (*tierras templadas*), and by the luxuriantly productive but unhealthy lower-lands (*tierras calientes*), which stretch inland 20 or 30 miles from the coast to the base of the mountains. The great table-land is a treeless plain, traversed by sierras, opening in extensive basins, and dropping to the E. coast by broad fertile valleys and rolling savannahs, with rugged bluffs overhanging the streams, and to the Pacific by steep slopes and woody defiles. The mountain system is a continuation of the Andes (a name never used in M.), divided into several branches, of which the principal, the Sierra Madre ('mother-range'), extends the whole length of the country from the Isthmus of Tehuantepec in the S. Another coast-range stretches along the Gulf of M., while the centre of the country is also traversed in a northerly direction by the Cordillera de Anahuac, which separates the valleys of M. and Puebla. Near the latitude of M. city six volcanoes rise in a line passing from E. to W. at right angles to the main ranges. Of these Popocatepetl, the highest, reaches an altitude of 17,540 feet; Orizaba, the most easterly, and now extinct, is 17,176 feet high; Iztaccihuatl, the twin of Popocatepetl, is 15,705 feet; Jorullo, the most recent (1759), is 7155 feet; Nevado de Toluca, 90 miles N.W. of Popocatepetl, is 16,616 feet; and Colima, the most westerly, is 10,800 feet. The lesser volcanoes of Jorullo and

Martin Tuxtla are now the most active, but Popocatepetl still occasionally sends forth clouds of smoke. There are many other mountains varying from 10,000 to 12,000 feet, but none in addition to those mentioned that rise above 15,000 feet, the line of perennial snow. In the N. the country, like the main plateau, is traversed by wide valleys and by lower mountains, while from the N.W. depends for 750 miles in a direction parallel to the coast the narrow rocky peninsula of Old or Lower California. In the extreme E. the peninsula of Yucatan, including Campeche, is a vast plain with only a slight elevation above the sea. The southern states of Chiapas and Tabasco are included geographically in the mountain system of Central America.

Hydrography.—M. is singularly destitute of navigable rivers. The boundary river, Rio Bravo or Rio Grande del Norte, 1800 miles long, separating M. on the N.E. from Texas, is by far the largest, but is only navigable by vessels of light draught for 60 miles of its lower course. On the Pacific slope the principal river is the Rio Grande del Santiago, 500 miles, in its upper course called the Lerma, in its middle course the Toluolotan. It rises in Lake Lerma, in the central valley of Toluca, flows W. through Michoacan and Jalisco, and is rendered unnavigable by numerous cataracts. The Rio Colorado which enters the Gulf of California is only a Mexican river for some 80 miles above its mouth. There are besides, many short rivers entering the Gulf of M. and the Bay of Campeche which are navigable in the lowlands, and of these the most important are Panuco, Alvarado, Coatzacoalcas, Grijalva, and Usumasinta. The Coatzacoalcas forms part of the commercial highway across the isthmus of Tehuantepec, where a gap in the Cordilleras is highly favourable to the construction of a proposed railway. The scarcity of water is the great drawback of the central plateau, which is only irrigated by a few torrents and springs. There are numerous large lakes, but most of them are tainted with carbonate of soda. Of these the chief are Chapala, 50 miles long, between Jalisco and Michoacan; Parras, in Coahuila; Texcuco, and four others in the vicinity of M. city. The Gulf of M. is fringed by many lagoons, of which the largest are Terminos and Tampico.

Climate.—In tropical or lowland M., where the mean annual temperature varies from 68° F. in the N. to 78° in the S., there are only two seasons, the dry and the rainy. These are of irregular duration, but the latter usually lasts from May to October, the heaviest rains falling in September. During the dry season, violent gales (*nortes*) frequently sweep along the E. coast, rendering navigation somewhat perilous. With a W. Indian climate, the coasts are remarkably rich in tropical vegetation, but are rendered almost uninhabitable by the prevalence of yellow fever. In the *tierras templadas*, a region of perpetual spring, the mean temperature ranges from 65° in the N. to 70° in the S. Here the atmosphere is occasionally foggy, the country being nearly on the level of the clouds. The *tierras frias* is only 'cold' in a relative sense, having a climate as mild and equable as that of Naples. Visitors in winter are caused some discomfort, however, by the rarefaction of the atmosphere.

Botany.—Nearly all the European cereals are grown in the uplands, and in addition to these M. produces an unusual variety of indigenous plants. Its flora embraces 100 species of timber trees and cabinet woods (mahogany, rosewood, ebony, &c.), 17 oil-bearing trees and plants, 12 species of dyewoods, 8 of gum trees, and over 60 of medicinal plants, including copaiba, sarsaparilla, and jalap. The staple food of the inhabitants everywhere is Indian corn: wheat and barley grow to perfection in the central valleys. The lower land produces abundance of rice, sugar, tobacco, cotton, coffee, cacao, and indigo, besides oranges, lemons, olives, mangoes, bananas, pineapples, grapes, yucas, &c. From the juice of the maguey or Mexican aloe is made the famous *pulque*, the national beverage, and in Yucatan a plant of the same species yields the *henique*, a fibre that is now the chief commercial product of the peninsula. There are many varieties of the cactus, one of which is cultivated extensively as food for the cochineal insect. The mulberry thrives in various parts, but the rearing of the silkworm has fallen off greatly of late years. Coahuila, Durango, and Sinaloa in the N. are the great cotton growing States, while the tobacco of Vera Cruz and Tabasco, the cacao (chocolate) of Tabasco, Oaxaca, and Chiapas, and the coffee of Michoacan and Colima are unsurpassed by those of any other country. A feature in the flora of M. is the abundance and variety of magnificent flowers.

Zoology.—The domestic animals of Europe are successfully

reared, and the wild animals are very numerous. The bison of American buffalo during mid-winter enters the country in immense herds from the forests to the N.W. Other wild animals are the puma, tapir, jaguar, ocelot, wolf, and coyote, several species of bears, deer, and monkeys, the sloth, skunk, glutton, and porcupine. Alligators abound in the lagoons and mouths of rivers; rattlesnakes and other venomous ophidians are common, as well as many noxious insects, including scorpions and tarantulas. The forests are alive with song-birds and brightly-plumaged parrots and humming-birds, and there are also many kinds of wild fowl and game. One of the most valuable animals is the cochineal insect, the chief article of export next to the precious metals. The domestic animals, with the notable exception of the turkey, a native of this country, were all introduced by the Spaniards, the ancient Mexicans not having succeeded in taming wild animals. The States in the N. are celebrated for the quality and numbers of their horses, sheep, and cattle. The coast-seas and lakes are well stocked with fish; amber is found on the shores of Yucatan; and there is a productive pearl fishery in the Gulf of California.

Geology and Mineralogy.—A great part of M. has experienced volcanic action, and vast fields are covered with basalt. Granite forms the foundation of the central table-land and of the mountain-system of Oaxaca, while the mineral-bearing superstructure is mainly porphyry. There are numerous caverns, that of Caca-huanilpa being one of the largest in the world. The mineral wealth of M. is enormous. More silver has been taken from its mines than from all the rest of the world, and the supply is practically illimitable. Its gold mines have only been surpassed by those of Peru, and later by those of California and Australia. Gold was the great mineral treasure of the Aztecs, who made little use of silver on account of the difficulty of reducing the ores. Early, however, in the Spanish period, gold gave place to silver as the great staple product of the country. In the first half of the 16th c. the silver mines of Tasco, Sultepec, Pachuca, &c., were developed by Cortes and his successors. Subsequently the rich mining districts of Guanajuato, San Luis Potosi, Zacatecas, and Durango were discovered and wrought, but it was not till the 18th c. that they attained a world-wide celebrity. The famous Veta Madre ('mother-vein') eventually yielded, according to Humboldt, one-fifth of the silver then current in the world, having far exceeded the mountain of Potosi in Upper Peru. The annual yield of the Veta Grande of Zacatecas alone amounted at times to £625,000, and the mines of Cotorce (San Luis Potosi) produced in seventy-seven years £31,250,000. Many proprietors of the great *huanzas* became counts and marquises, virtually by purchase from the Spanish crown, and the vast mineral wealth of M. was in the hands of a wealthy aristocracy till the long war of independence (1810-20) ruined the mining interests. On the establishment of a republic a fever for Mexican mines pervaded the London money-market, and many English companies were formed, but nearly all of these collapsed within a few years, mainly because of bad management and the ignorance of the mining engineers. The mines are now almost entirely in the possession of Mexican capitalists, and are gradually recovering their prosperity. The Spanish 'mining-code,' the most elaborate in the world, is still in use, and every year is bringing improved processes of extraction and reduction, cheaper means of transport, and larger supplies of coal and quicksilver. In 1876 there were eleven mints in M., and these coin on an average £4,167,000, of which less than £20,800 is in gold. The total production of the mines up to 1875 is estimated at £895,833,000, and the total coinage for the same period is stated at £638,262,515, of which not more than 5 per cent. was gold. Copper is also found extensively. Iron occurs in immense masses in Coalcoman, Lagos, and Durango; in the last State the Cerro del Mercado is a solid mountain of magnetic iron ore. Valuable quicksilver mines have recently been wrought in Morelos and Guerrero, and small deposits of coal have been discovered in many parts, though it is nowhere mined on a profitable scale. Other minerals are tin, lead, bismuth, and platinum; quarries of marble, alabaster, gypsum, and rock-salt are numerous; sulphur is found in the craters of the volcanoes, and mineral springs occur in many localities.

Industry, Commerce, &c.—The great mass of the inhabitants are engaged in agriculture, either in the tillage of their own small plots, or in the cultivation of the great plantations. In

addition to the mining industries, there are also a few iron-foundries, several extensive sugar refineries (in Morelos), and cotton and woollen factories, a number of small paper, grist, and sawmills, &c. The goldsmiths excel in filigree work, and superior glass-ware and porcelain are made at Puebla, Texcoco, and other cities. Other industries are the making of *rebozos* or shawls, and of saddlery of fine quality, and the weaving by hand of cotton and woollen cloths. In 1874 the total value of exports was £5,087,000, and of imports £5,697,000. The value of silver exported was £3,000,000; the other leading exports were copper ores, cochineal, indigo, hides, mahogany, and other woods, heniquen or Sisal hemp, coffee, vanilla, tobacco, India-rubber, orchil, and sarsaparilla. In 1875 the exports to Great Britain amounted to £721,907 (silver £7919), and the imports from Great Britain to £884,901. The Pacific coast has many splendid harbours, but on the Gulf side Acapulco is the only good one, all the bays and inlets being silted up by the current of the Gulf. Of 3131 vessels that entered the ports in 1874, 2227 were coasters and other vessels under the Mexican flag, 332 belonged to the United States, 162 to Great Britain, 115 to France, and 112 to Germany. The roads throughout M. are wretched, and mail and passenger traffic is effected by twenty-four lines of diligences managed by a single company. Pack-mules and ox-carts are employed in the transport trade. In July 1876 there were 372 miles of railway open for traffic, and 300 additional miles were in course of construction. The main line, the 'National Mexican,' runs from Vera Cruz to the city of M., with a branch to Puebla. The telegraph lines are (1876) 5760 miles long.

Government, Army and Navy, &c.—The constitution of 1857, which declares M. a federal republic, and grants to each State the power to manage its own local affairs, was twice overthrown and restored (1858-60 and 1863-67), and was amended in 1873-74. The legislative power is vested in a Congress, consisting of a Senate and a Lower House of Representatives, and the executive in a President, who is elected by Congress for four years. Deputies (331) are elected to the Lower House by popular suffrage for two years; the senators (56) are elected for four years. The President is assisted in carrying on the administration by a council of five members, who are heads of the departments of Justice, Finance, Army and Navy, Foreign Affairs, and Public Works. The revenue, chiefly derived from import and export duties, was returned in the budget of 1875-76 at £3,741,407, and the expenditure, of which nearly a half is for the army, at £4,985,955. The finances of M. have been for many years in the greatest disorder, the expenditure constantly exceeding the revenue. In 1876 the total public debt was estimated at £79,100,000, but the whole of the debt has been repudiated by the republic except £7,000,000, and even the interest on this sum has not been paid for many years. M. maintains (1876) an army of 21,136 men and 1251 officers, but the navy is little more than nominal, consisting of four steamers recently constructed for coast-guard service.

Religion, Education, &c.—The Roman Catholic Church formerly owned about one-third of all M., but in 1856-59, its property was nationalised, its convents abolished, and many of its churches were sold or seized for public use. Since then toleration has been extended to all churches, State recognition to none. The Roman Catholic hierarchy has three archbishops and twelve bishops. There are several thriving American Protestant missions in M., besides the 'Church of Jesus,' an undenominational Protestant organisation, which has some twenty churches and mission-stations. In 1876 the sum voted for education was £13,790. The University of M., abolished in 1856, has been replaced by a military college, and by special schools of law, medicine, music, agriculture, engineering, mines, commerce, fine arts, and literature. The local governments of the various States support common schools in all the larger towns, and higher schools in the capitals. Throughout the republic there are no fewer than 40,000 schools, and the number is increasing. Spanish is the universal language of the white population, but as many as thirty-five distinct dialects, including Aztec, are spoken by the Indian tribes.

Ancient Civilisation and Modern History.—The Toltecs occupied M. from about the 7th c. to the 12th c., when they gave place to the Aztecs. To the latter the Toltecs bequeathed an elaborate form of government, a set of sing-

ularly humane laws, a calendar more exact than that of Egypt, Greece, or Rome, a system of hieroglyphics, many advanced processes in agriculture and mining, and various superior arts, such as the weaving of textiles, a species of feather-embroidery, and the making of pottery. Among the wonders of M. to the present day are the remains—especially at Palenque, Uxmal, and Mitla—of vast palaces, pyramids, aqueducts, and bridges, evincing the marvellous skill acquired by this isolated people in the arts of construction and sculpture. The Aztecs, a sterner people, though they had an emperor, were actually governed, and that most despotically, by the priests. They believed in a supreme invisible Creator, and in some 200 minor divinities, and practised human sacrifice to an extent and with a contempt of life perhaps unexampled in the history of pious atrocity. In 1519 the Spaniards, lured by the fabled wealth of the country, descended in force under Cortes (q. v.) on the coast of Vera Cruz, and after some two years of desperate fighting were successful in asserting Spanish supremacy. The conquest was accompanied by fearful carnage, and subsequently every vestige of Aztec civilisation was stamped out by the Catholic clergy. For three centuries M. remained the principal colony of Spain, and its government was mainly characterised by pride, avarice, and intolerance. At last the oppression of the natives by the Gaculupines or pure Spaniards led to an insurrection which lasted for eleven years, and resulted in the independence of M., 1821. After the short-lived rule of the dictator, Iturbide (q. v.), a republic was proclaimed by Santa Anna (q. v.) in 1822, but the country was utterly disorganised by the struggles of the aristocracy (*Escosseres*) and reformers (*Yorkinos*), and for the next twenty years M. passed from one dictatorship to another. Texas secured its independence in 1836, and its subsequent union with the United States led to the war of the latter power with M. in 1845-48. The two great events in the later history of M. are the 'war of reform,' or party struggle for power (1857-60), and the war of 'French intervention' (1861-67), through both of which the life of the republic was zealously defended by Benito Juarez. To the latter period belongs the ephemeral 'empire' presided over (1864-67) by Maximilian (q. v.). Juarez (q. v.) remained President till his death in 1872, and had the good fortune to see public order restored, and the constitution for which he had so nobly striven established on a firmer basis. He was succeeded by his chief follower Sebastian Lerdo de Tejada, who still holds office in 1877. See Humboldt's *Königreich's Neu-Spanien* (1809-13), Prescott's *Conquest of M.* (1843), Alamán's *Historia de Mexicana* (5 vols., Mex. 1849-52), Chevalier's *Le Mexique ancien et moderne* (Par. 1866), Helps' *Life of Cortes and Conquest of M.* (1871), Myer's *Remains of Lost Empires* (1873), Vignes' *Travels in M.* (2 vols. 1874), and Cubas' *Geographie de Mexicana* (Mex. 1874).

Mexico, capital of the republic of the same name, is situated near the S.W. corner of Lake Texcoco, on a fertile plain, 7435 feet above the sea, and surrounded by lofty volcanic mountains, 200 miles W.N.W. of Vera Cruz by rail. It is a beautiful city, the architecture being solid and handsome, occupies a level site, and has a circumference of 16 miles. The cathedral, erected 1593-1677 at a cost of \$2,500,000, is unsurpassed for the splendour of its decorations. Other notable buildings are the vast government palace, formerly the residence of the Spanish viceroys; the old Inquisition, founded in 1571, now used as a school of medicine; the National Museum, containing the great calendar stone of the Toltecs, a large statue of Huitzilopochtli, and other Aztec remains; the academy of San Carlos, which has the largest and finest collection of pictures in America; the National Library, lately rebuilt, with its 103,000 vols.; and the 'Cinco de Mayo' Library, opened in 1870. Water is supplied by two noble aqueducts, and the markets are stocked with fruits and flowers brought on canals from the *Chinampas* or 'floating islands.' Besides the Alameda, which is shaded by superb trees, the public resorts are the Paseo de la Vigna, extending along a canal of that name, and the Paseo de Bucareli, the great public drive, adorned with trees and fountains. M. is of but slight commercial importance. Its manufactures are cigars, gold lace, saddlery, &c., and there is considerable transit trade, and some industry in connection with the mint. It was built by the Spaniards on the site of the ruined Tenochtitlan. Pop. in 1803, 137,000; in 1838, 205,430; in 1875, 230,000.

Mexico, Gulf of, the great inlet of the Atlantic on the E.

shore of N. America, between the peninsulas of Yucatan and Florida. It has an area of some 800,000 sq. miles, and is entered through the Yucatan Channel by the Gulf Stream (see CURRENTS), which traverses it in a curve, and leaves it through the Channel of Florida. The temperature of its waters is thus raised several degrees above that of the Atlantic.

Mey'erbeer, Gia'como, a gifted operatic composer, was the son of a rich banker called Beer, and was born September 5, 1794, at Berlin. He studied music under Lauska and B. A. Weber, and dramatic composition under the Abbé Vogler at Darmstadt. After composing *Jephthah* (1812) and *Die beiden Khalifen*, he went to Italy and heard Rossini's new works, which gave his activity a fresh direction. In Italy his first successful operas were produced, the best of these being *Crociato* (1825). But it was at the Grand Opera in Paris, in which city he settled in 1826, that he achieved his greatest triumphs. The fantastic and beautiful *Robert le Diable* (1831), evoked delirious enthusiasm. His magnificent *chef d'œuvre*, *Les Huguenots*, appeared in 1836. M.'s later grand operas are *L'Etoile du Nord* (1847), *Le Prophète* (1849), *Dinorah* (1859), and *L'Africaine* (1865; posthumous). In all, he wrote 18 operas, 2 oratorios, 6 sacred works, 11 cantatas, and a multitude of songs and instrumental pieces. M. held the office of General Musical Director to the King of Prussia from 1841 till his death, which took place at Paris, 2d May 1864. See H. Mendel's *G. M.; sein Leben und seine Werke* (Berl. 1869).

Me'zen, a town in Russia, government of Archangel, 140 miles N.E. of the town of Archangel, on the estuary of a river of the same name, which falls into the White Sea, after a N.W. course of 450 miles. M. has a considerable trade in furs and fish. Pop. 2000.

Mézières, a town of France, capital of the department of Ardennes, on the right bank of the Meuse, opposite Charleville, with which it is connected by a bridge. It is strongly fortified, and has a fine church of the 15th c., an arsenal, and antiquarian museum, besides tanneries, powder-mills, and iron-foundries. Pop. (1872) 4031. M., which was successfully defended by Bayard (1521) against 35,000 Austrians, capitulated to the Germans under General Von Kamecke, January 2, 1871.

Mezqui'te is the vernacular name of *Prosopis glandulosa*, a leguminiferous tree (*Papilionaceæ*) of Texas, and the region to the west. In some situations it grows to a height of 30 feet, and yields an excessively hard and durable timber; it also affords a large quantity of a gum resembling gum-arabic. *P. pubescens*, also a native of Texas, New Mexico, and California, is the screw-bean or screw-M. of the Americans, and the Tornillo of the Mexicans. It is named from the screw-like form of its pods, being twisted into rigid cylinders more than an inch long. It has recently been recommended for growth in Australia, as a food for cattle and horses.

Mezzofan'ti, Giusepp'e, was born at Bologna, September 17, 1774. He was ordained priest in 1797; after delivering a course of lectures on Arabic, was elected Professor of Greek and Oriental languages in the university of his native town; in 1833 became keeper of the Vatican library at Rome, and obtained a cardinal's hat five years later. He died at Rome, March 15, 1849. His fame rests on his linguistic acquisitions—greater by far than those of any contemporary. He spoke more than fifty languages, with many of their dialects, and had so fine an ear that in conversing with foreigners he detected the smallest provincialisms, replying often in the appropriate *patois*. Russell's *Life of Cardinal M.* (Lond. 1858; 2d ed. 1863).

Mezzoju'so (a corruption of the Arab. *Mesul-Yusuf*, 'station of Joseph'), a town of Sicily, in the province of Palermo, 23½ miles S.S.E. of the city of that name. It is one of four Albanian colonies—Piano dei Greci, Palazzo Adriano, and Contessa being the others—founded here since 1482, and a portion of its inhabitants still partially retain the Skipetar language, and adhere to the Greek Church. Pop. (1874) 7161.

Mezzo-Riliev'o. See ALTO RILIEVO.

Mezzotint'o (Ital. 'middle-tint'), a method of engraving invented in the 17th c. by Colonel Louis von Siegen, in the service of the Landgraf of Hessen-Kassel, from whom Prince

Rupert, often called the inventor of the process, acquired his knowledge of it. M. is rapidly executed, and consists in indenting small dots over the metal surface, which in this condition would yield an impression equal to the darkest shades of the picture. The subject is then traced, and the lights and shadows are obtained by scraping and burnishing the burr of the plate. See ENGRAVING.

Mhow, an important British military station in India, within the territory of Holkar, the Mahratta Rajah of Indore, 2019 feet above the sea, 13 miles S.W. of Indore, and about 420 miles N.E. by rail from Bombay. It is the headquarters of a military division, numbering 2800 European and 3800 native troops, and the cantonments are large and well built. It has been the scene of some serious outbreaks of cholera, and also of a great military scandal. In 1857 the sepoys broke into mutiny, but the place was saved by the energy of the officer in charge of a battery of European horse artillery, though the army of Holkar had revolted at Indore.

Mia'ko, or **Kiyo'to**, the ancient capital of Japan and former residence of the Mikado, is situated towards the S. of Nipon, about 50 miles N.E. of the thriving port of Hiogo, with which it is connected by a railway opened in 1876. It lies picturesquely to the S.W. of the great Lake Biwako or Umi, and is in great part composed of deserted mansions of the old daimios. M. is now an educational centre. In 1871 there were sixty-four public schools. Foreign languages, English, French, and German, are widely taught. Pop. (1872) estimated at 300,000.

Mia'mi, a river in Ohio, U.S., rises towards the W. of the States at a height of 1335 feet, flows S.W. through a rich, populous valley, and joins the Ohio River below Cincinnati, after a course of 150 miles. *M.*, or *Minicami*, was the name of a tribe of Algonquin Indians who formerly occupied great part of Ohio and Indiana.

Mian-Mir, the military cantonment of Lahore, 3 miles E. from that city; pop. (1868) 15,757. The troops were removed here in 1852, on account of the unhealthiness of Lahore. The garrison now includes about 1000 Europeans. In 1857 four regiments of sepoys were quickly disarmed, on the first news of the Mutiny at Meerut.

Miasmatic Diseases (Gr. *miasma*, 'a stain, pollution'), according to the nosology of Dr. Farr, form an order of the zymotic class of diseases, and are caused by (1) paludal malarious poison; (2) animal malarious poison; and (3) specific disease poisons. The term *miasma*, however, is generally used as synonymous with *malaria*, and M. D. are described as those depending upon effluvia proceeding from the surface of the earth. The Italian physician, Lancisi, in his work, *De Noxiis Paludum Effluviis*, published about 1695, was the first to put forth correct ideas regarding malaria, which consists in certain invisible effluvia or emanations from the surface of the earth which were formerly called *marsh miasmata*. The malaria is a specific poison, producing specific effects upon the human body, and is not simply bad or impure air; but the exact nature of this telluric miasma, and the circumstances under which it is formed, have not as yet been definitely established. Chemical analyses and microscopic examination of the air have not detected any special ingredient in localities where M. D. are prevalent; but such localities are most commonly marshy places, although not invariably so, and the influence of the poison in tropical climates is greater than in the temperate zone, leading to the inference that malaria is a product of vegetable decomposition occurring under certain conditions of heat and moisture. The endemic character of M. D. pertains more to locality than to climate; for such diseases are not equally prevalent in all the localities of which a district may be composed. M. D. vary from simple intermittent fever to a fever of a pernicious type, and the soil from which they originate varies both in constitution and appearance from the old classic marsh to the sandy desert. The more unhealthy localities, in the tropics, are the lowlands along the coast bordering upon estuaries where large rivers empty themselves into the sea, and which are periodically inundated. Heaps of decayed vegetable matter are deposited at the mouth and along the borders of the rivers, and this with the rank marsh vegetation forms along the coast an extensive zone of endemic malaria. In all malarial districts the period of infection is most intense shortly before sunrise and after sunset, when the miasma

drawn out by evaporation is suspended with the watery vapours under the form of a fog on low-lying surfaces. In inter-tropical Africa, more especially, paludal fevers are developed among the labourers, on the breaking up of virgin soil for agricultural purposes, in districts where M. D. were not formerly prevalent; but after two or three seasons of cultivation, more especially if the land be drained, such fevers disappear and the place becomes comparatively healthy. In estimating the dryness of the soil its superficial appearance is often deceitful; for the soil may be a level plain of sand, with a perfectly dry surface, and with little or no vegetation, but it may be found to be saturated with water to within a few inches of the surface, and to be an intensely malarious district. Such was found to be the nature of the soil when our troops took up the encampment of Rosendaal and Ousterhout in S. Holland in the summers of 1748 and 1794, when they suffered so severely from M. D. So also along the coast of Peru, where vegetation is very scarce and where ague is very common, the miasma finds its way freely through the open sand to the atmospheric air. In many hot climates, the most deadly sites for encampments have been the dried-up beds of rivers or their immediate vicinities, and, as a general rule, troops are not encamped where the level of the soil water is near the surface. M. D. are frequently prevalent in rocky countries, as Gibraltar and the Ionian islands, but in such cases the rocks are permeated by water; and, during the hot season, the difference between the temperature of the rocks and the atmosphere is often very great. Humboldt, on ascending the Orinoco, found the country at the great fall depopulated with fever, which the natives ascribed to the heat of the rocks, their temperature being 118° F., while that of the surrounding atmosphere was only 79°. Some soils are peculiarly favourable to the decomposition of vegetable matters, and those countries most celebrated for M. D. are said to have a similar geological formation, so that marsh miasma may be the product of the reaction which takes place between certain atmospheric conditions and the hydro-geological elements of the soil.

In regard to infecting distance, it may be stated that the danger is in proportion to proximity to the infecting focus. In Italy, an altitudinal range of from 1400 to 1600 feet is necessary to secure immunity; but in the W. Indies an elevation of from 2000 to 2500 feet is necessary. In Eastern Africa, where M. D. are notoriously prevalent, a considerable degree of immunity is secured by having the sleeping apartments in the upper flat of the house, the rooms being well ventilated, and the bed being enclosed by a close-meshed mosquito curtain. The extent to which miasma may extend over land is much more difficult to determine; but it is well known that a belt of trees intercepts to a considerable extent its extension, the supposition being that the vapours condense on their leaves. See AGUE.

Mica (from Lat. *mica*, 'I glitter'), a mineral consisting of silicate of alumina, with small quantities of the silicates of potash and iron oxide. It has a pearly lustre, is tough and elastic, occurs in laminae of extreme tenuity, and is ordinarily obtained crystallised in oblique rhombic prisms. There are three well-marked varieties, known as *Muscovite*, *Phlogopite*, and *Biotite*. The first is biaxial, occurs in granites and other igneous rocks, and has lethia and magnesia as well as potash in its composition. The second is also biaxial, and is found in granular limestone and serpentine. The third, known also as *Magnesia M.*, is uniaxial, and contains large quantities of potash, magnesia, and oxide of iron. Formerly huge masses were found in Siberia; and the mineral abounds in Finland, Greenland, Sweden, Norway, Maine, New Hampshire, &c.

Micah (Heb. a contraction of *Micayahu*, 'Who is like Jehovah?' cf. 2 Chr. xiii. 2), a Hebrew prophet called the Morasthite (i. 1), that is, a native of Moresheth (perhaps in the territory of Gath, cf. i. 14), in order to distinguish him from Micah the son of Imah (1 Kings xxii. 8). The time at which he prophesied is stated in the superscription of the Book of M., which is the sixth of the minor prophets, as the reigns of Jotham, Ahaz, and Hezekiah, kings of Judah, i.e., within B.C. 758-697; according to which he was the contemporary of Isaiah, and somewhat later than Joel, Amos, and Hosea; but the prophecies contained in the book, at any rate all but i. 1-16, were uttered in the reign of Hezekiah (cf. Jer. xxvi. 18). The style of M. is highly poetical, very similar to that of Isaiah, especially in the frequent play upon words.

Mica-Schist or **Mica-Slate**, a metamorphic rock with the same constituents as gneiss, but containing more mica. It is ordinarily distinguished from gneiss by its foliated structure; but in many cases it appears to be simply less metamorphosed than this other widely-distributed metamorphic rock.

Mic'hael, St. (Heb. 'who is like unto God'), the 'first of the chief princes,' or archangels (Dan. x. 13), 'which standeth for the children of thy people' (xii. 1), he who 'disputed with the devil about the body of Moses' (Jude ix.; cf. 2 Peter ii. 11), and 'fought with his angels against the dragon' (Rev. xii. 7). In Rabbinical tradition he was regarded as the tutelar saint of the Jewish nation, as now he is the patron of the Church militant, and guardian of redeemed souls. He is usually represented in art as clad in armour, a sword in one hand, and in the other a pair of scales, with which he weighs the souls of men. Michaelmas, or the Feast of St. M. and All Angels, falls on September 29.

Michael VIII., surnamed **Palæologus**, the founder of the dynasty of the Palæologi. See BYZANTINE EMPIRE.

Michaelis, Johann David, a German theologian, born at Halle, 27th February 1717, is the greatest name of a family distinguished in biblical science since the Reformation. After studying at Halle, he travelled in England and Holland, was made (1745) Professor of Philosophy at Göttingen, where from 1753 to 1770 he was joint editor of the *Göttinger Gelehrten Anzeigen*. During the Seven Years' War he was chiefly engaged in making preparations for an expedition of discovery to Arabia, which was subsequently undertaken by Karstens Niebuhr and Forskaal. M. died at Göttingen, 22d August 1791. In a period of transition from the old orthodoxy, his works helped to pave the way for the subsequent rationalism. The chief are *Einführung in die Göttlichen Schriften des Neuen Bundes* (2 vols. Gött. 1750; Eng. trans. by Bishop Marsh, best ed. 1823), *Das Mosaische Recht* (6 vols. Frankf. 1770-75; Eng. trans. by Dr. A. Smith, 1814), and *Die Moral* (Stäudlin, 3 vols. Gött. 1792-1823). See his *Lebensbeschreibung von ihm selbst abgefasst* (Leips. 1793).

Michaelmas Daisy. See ASTRÆ.

Michaelmas Day, 29th September, is an English money term. There is also a law term of Michaelmas. It begins on the 2d, and ends on 25th November.

Michélet, Jules, a French historian, was born at Paris, August 21, 1798, educated at the Lycée Charlemagne, and afterwards taught languages, philosophy, and history for a livelihood. In 1821 he became professor in the Collège Rollin, in 1830 chief of the historical section of the royal archives, in 1838 Professor of History and Morals in the Collège de France, and in the same year was elected a member of the Académie des Sciences. The Revolution of February 1848 opened the way to a political career, but, though an ardent political theorist, he wisely shunned the perils of office. Nevertheless after the *coup d'état* he lost his professorship by refusing to swear fidelity to Louis Napoleon. M. died at Hyères, February 9, 1874. His literary career began in 1826 with *Les Tableaux Synchroniques de l'Histoire Moderne*. This was followed in 1831 by *Principes de la Philosophie de l'Histoire* (Par. 1831); *Précis de l'Histoire Moderne* (Par. 1833), a work which has gone through numerous editions; *Origines du Droit Français* (1837), &c.; but the greatest monument of his genius and industry is the *Histoire de France* (16 vols. 1837-67; new ed. 1871, et seq.), parts of which are published as separate monographs—e.g., the *Histoire de la Révolution Française* (7 vols. 1847-53; new ed. 1868). The 2d and 3d vols. of *L'Histoire du XIX^e Siècle* were issued posthumously in 1875. During his tenure of the chair of history he assailed with more than Gallic vehemence the principles of the Jesuits, and the books in which his impassioned controversy was carried on, *Des Jésuites* (1843), *Du Prêtre, de la Femme et de la Famille* (1844) profoundly stirred his countrymen. During the Napoleonic regime, without abandoning the field of political and controversial literature, to which belong *La Pologne Martyre* (1863) and *La Bible de l'Humanité* (1864), he turned aside to quiet paths in which he met no foe, and in his *L'Oiseau* (1856), *L'Insecte* (1857), *La Mer* (1861), *La Montagne* (1868) proved the versatility of his vivacious genius. His histories are written with an occasional naïveté like that of the early chroniclers, but they are less systematic records of events than brilliant pictures from separate epochs. He is in-

tensely democratic in his ideas, but there is nothing ignoble—nothing of the sycophant—in his admiration of the 'people.' He is haunted by the dream of a noble nation, and is merciless in his denunciation of the crimes that hindered its growth in the past. See Gabriel Monod's *J. M.* (Par. 1875).

Michigan, one of the northern central States of the American Union, is bounded N. by Lake Superior and St. Mary River, S. by Wisconsin, Ohio, and Indiana, W. by Lake M., and E. by Lakes Huron, St. Clair, and Erie, and by the rivers Detroit and St. Clair. Area, 56,451 sq. miles; pop. (1870) 1,334,031. M. consists of two distinct peninsulas, the smaller or more westerly extending between Lakes Superior and M., the larger separating Lake M. from Huron and Erie. The two peninsulas are very irregular in outline, and are divided from each other by the Mackinaw Straits. The former, which projects to the E., comprises about one-third of the whole area, and has a broken, mountainous surface, rich in minerals, and partly covered by dense forests. Its watershed is formed by the Porcupine Range, which reaches a height of 2000 feet, and sends to the lakes the rivers Ontonagon, Itequamenon, Escanaba, &c. The lower peninsula projects in a northerly direction, and is a rich, level region, cultivated extensively, and watered by the Cheboygan, Saginaw, Racine, Kalamazoo, St. Joseph, &c. The lake-coast of M. is over 1100 miles long, is much indented, and fringed with numerous islands, of which the chief are Isle Royale, the Beaver, Fox and Manitou, and the Drummond and Sugar Islands. The shores of the lakes, especially of Lake M., are mostly steep, water-worn bluffs. The upper peninsula is in great part covered with Eozoic formations, and the rocks are richly charged with copper ores. The lower peninsula consists wholly of the Appalachian series, the central portion being occupied by coal-measures to the extent of 7000 sq. miles. M. stands in the first rank of mining States, and the products include not only coal, iron, and copper, but salt, limestone, and gypsum, petroleum, slates, &c. In 1874 there was raised in 34 mines 21,894 tons of copper; in the 60 mines of the Marquette iron district, 935,400 tons of iron ore (value \$5,058,979). The climate varies much over so wide an area; in 1875 the mean temperature was 43.06, the rainfall 28 inches, the fall of snow (which affords good protection for wheat crops) 63½ inches. The 'Burr Oak' soils on the western slopes of M. are exceedingly productive. Of the whole area, 40 per cent. is under wood; the white pine forests are the most valuable in the U.S. In 1875 the arable area was 3,500,000 acres, of which 1,250,000 were in wheat, 710,000 in Indian corn, 329,000 in oats, and 1,016,000 in hay, besides smaller areas under rye, barley, and potatoes. On 1st January 1876, M. had 361,100 cows, and 410,000 oxen and other cattle; 3,450,600 sheep, and 459,700 hogs. In 1874 the product of the mines was \$16,000,000, and of the forests \$45,000,000. The lumber trade is equal to that of Maine, New York, Pennsylvania, Wisconsin, and Minnesota put together. There are (1874) 3993 miles of railway in the State. The chief towns are Lansing (the capital), Detroit, Ann Arbor, Grand Rapids, East Saginaw, Jackson City, and Bay City. The name M. is a contraction of the Indian word *Nicchi Saugweyan*, 'lake country.' The first permanent settlement was that of a French mission at the Falls of St. Mary, in 1641. After the War of Independence the territory was retained by Great Britain, but was finally ceded to the U.S. in 1796. It became a State in 1837.

Michigan, Lake, the longest, and, after Superior, the largest of the great American lakes. It is the only one of the five that lies entirely within the limits of the United States, and is confined on the N. and E. by the two parts of Michigan, on the W. by Wisconsin and Illinois, and on the S. by Illinois and Indiana. Its area is 25,600 sq. miles, its extreme length 340 miles, its breadth 70, and its mean depth 1000 feet. The chief indentation is Green Bay, in Wisconsin. M. receives many streams, is drained through Mackinaw Straits, 25 miles wide, into Lake Huron, and communicates by canal with the Mississippi. Though subject to violent storms it is a great commercial highway, especially for wheat, and has valuable white fish, large trout, and other fisheries. On its W. shore are Chicago and Milwaukee.

Mickle, William Julius, born at Langholm, Dumfriesshire, September 29, 1734, received two years' schooling at the Edinburgh High School, and having failed in business as a

brewer, came to London in May 1763 to seek a livelihood by his pen. He gained the patronage of Lord Lyttelton, but was glad to accept the post of corrector in the Clarendon Press, Oxford (1765), and here it was that he wrote the *Concubine* (1767), a Spenserian poem, republished as *Syr Martyn* (1778); a translation of Camoens's *Lusiad* (1775); a new and revised edition appeared in 1877; his ballad of *Cumnor Hall*, and other poems. As secretary to Commodore Johnstone (1779) he visited Lisbon, where he was admitted a member of the Portuguese Academy, and in 1780 he became an agent of prizes. He died at Forest Hill, in Oxfordshire, October 28, 1788. There is a collected edition of his poems (3 vols. 1806), with a memoir by the Rev. J. Sim. The exquisite song, *There's nae Luck about the House*, probably written by M. prior to 1760, has been also attributed to Jean Adam, who died in the Glasgow Workhouse in 1765. See the *Athenæum*, January 27, 1877.

Mic'rococosm (Gr. 'a little world'), a name given to man by the philosophers of the Middle Ages, who fancied they traced relations between the different parts of his nature corresponding to relations between the different parts of the universe. The physical universe was in contradistinction called *Macrocosm* ('a great world').

Microles'tes, a genus of extinct *Marsupial* (q. v.) mammals, which present the oldest traces of mammalia in Europe at least. The remains of *M. antiquus* occur in the Upper Trias in the Keuper strata of Würtemberg. These consist of a few teeth only, but there is no doubt that the animal was a marsupial.

Microm'eter (Gr. *mikros*, 'little,' and *metron*, 'a measure'), an optical instrument for measuring very small distances and angles. The simplest form is the *wire M.*, which consists of three very fine wires set in the diaphragm at the focus of the object-glass of a telescope. The one wire is fixed centrally in the field of view, while the other two are perpendicular to it, and so adjusted with milled-head screws, &c., as to be easily moved backwards and forwards in the direction of the fixed wire. By rotation of the diaphragm, the fixed wire may be set in any required direction, so as, for example, to coincide with the line joining two stars. By moving the two cross wires from coincidence till each bisects one star, a measure of the distance between the stars is at once obtained in terms of the number of turns of the M. screws, and this is reduced by a known and previously ascertained formula to standard arcual units. Various modifications of the wire M. exist, but the above indicates sufficiently the principle of all. Fraunhofer's *suspended annular M.* consists of an accurately turned metallic ring set in a perforated plane glass plate; and the relative positions of contiguous stars are easily obtained by observations of the times at which they suffer eclipse by the substance of the ring and at which they reappear. Reticules and circular micrometers measure in the same way—by observing the lapse of time. The *Heliometer* (q. v.) is another and very accurate form of M. Abbé Rochon made an ingenious application of the laws of double refraction to the construction of a M. Two triangular prisms of the same doubly-refracting crystal are joined so as to form a parallelepiped, while their axes of crystallisation are at right angles to each other. If this apparatus is placed in the axes of the telescope between the object glass and eye-piece, two images of the object viewed are formed, which, however, coincide when the prism is at the focus. The distance of the one image from the other depends upon the distance of the double prism from the focus. Hence by moving the prism forwards until the images originally coincident are now made just to touch at one point, data are supplied for determining the apparent diameter of the object. See Herschell's *Outlines of Astronomy*.

Mic'roscope (Gr. *mikros*, 'little,' and *skopō*, 'I see'), an optical instrument which enables us to view minute objects by forming magnified images of them. Its principle depends upon the laws of the refraction of light (see OPTICS). If a pencil of rays, parallel to the axis of a convex lens (see LENS), are allowed to pass through the lens, they are so refracted as to converge to a point known as the principal focus, after which they continue diverging indefinitely. If a luminous source be placed at the focus, the rays constituting that portion of its light which falls upon the lens are refracted so as to become parallel. Should the source of light be nearer to the lens than the focus, the

refracted rays are still divergent, though not to such an extent; while if the source be beyond the focus, the refracted rays are rendered convergent so as to meet at a point which is mathematically related to the distance of the luminous source from the focus. The former arrangement is that which holds in the ordinary magnifying-glass or simple M. Here the object to be viewed is placed within the focal distance of the lens, and the slightly diverging refracted rays are received by the eye held close to the other side of the lens. The distance of the object from the lens must be adjusted so that each point has its image formed at that distance from the eye at which an object is seen distinctly. Hence the lens must be adjusted for each eye; and the image is of greater dimensions than the object, and the greater the further sighted the observer is. Long-sighted persons, who cannot view near objects distinctly, use concave spectacles or glasses, which form an image at a sufficiently great distance to be viewed with ease. Such single lenses date from the 14th c., and were the sole aids with which Leeuwenhoek, Swammerdam, and Lyonnet made their famous microscopical researches. The smaller the focal distance of the lens, the greater the magnifying power.

The *compound M.* dates from the 17th c. It is a combination of two lenses, the one acting as the object-glass, the other as the eye-glass. They are fitted into a double tube, which admits of the motion of the eye-piece so as to suit all sights. The tube is usually set nearly vertical; and the object to be viewed is set beneath the object-glass at a distance a little beyond the focal distance. The rays from each point of the object collect after refraction at a focus; and the result is an inverted image of the object formed in the tube. This image is then viewed by the eye-piece, exactly as the original object was viewed by the simple M. In the best microscopes, the eye-piece is not a single lens, but a combination of two, invented by Huyghens, the magnifying power of which is greater than could conveniently be obtained, on account of spherical aberration and chromatic effects, by a single lens. Achromatic arrangements are now indispensable in a really efficient M., in the construction of which such names as Ross, Varley, Nachet, Smith, Beck, Browning, &c., are widely celebrated. The *solar M.*, first suggested by Lieberkühn in 1738, throws an image of a transparent object, upon which the sun's rays have in the first place been concentrated by a powerful lens through a series of glasses, upon a screen, where it may be viewed by a large audience. See Queckelt, *On the M.* (1855); Carpenter, *The M. and its Revelations* (1862); and Beale, *How to work with the M.* (1864).

Microzamia belongs to the remarkable family of plants named *Cycadaceæ* (q. v.), and is a subdivision of the genus *Zamia* (q. v.). Several interesting species of this genus occur in Australia, of which one with long slender leaves like palms is there used by the Roman Catholics for church decoration on Palm Sunday. The underground stem yields a gum like tragacanth.

Midas, a Phrygian king, son of Gordius and Cybele, who being offered by Dionysus the fulfilment of whatever he should ask, requested that everything he touched might be converted into gold. But soon M., like to die of hunger, was glad to get rid of the dangerous blessing by washing in Pactolus, which has ever since had gold among its sands. According to another legend, Apollo gave M. ass's ears, because in a musical contest between that god and Pan he had awarded the prize to the latter.

Middelburg, a town in the Netherlands, capital of the province of Zeeland, in the interior of the island of Walcheren, with the coast of which it is connected in three directions by about three miles of navigable canal, and in two by the Rozendaal-Vliessingen railway. M. has many fine buildings and squares, a town-house (built 1468), with a high Gothic tower, and twenty-five life-size statues of the Counts of Flanders and Zeeland, and near the centre an old abbey of Our Lady. It was formerly an important Hanse town, having extensive commerce with the E. and W. Indies and the Levant, but its trade has greatly declined. There are manufactures of leather, soap, vinegar, and lace. Pop. (1870) 14,714.

Middle Ages, a term applied to the 1000 years extending from the overthrow of the Roman Empire in the 5th c. by the barbarians to the capture of Constantinople by the Turks in 1453, and the Renaissance (q. v.) which sprang from that calamity.

The first half of the M. A. are sometimes distinctively termed the 'Dark Ages,' because of the gloom that fell upon Europe with the overthrow of the Roman civilisation. But it was not the darkness of contented ignorance and dull apathy. The new races struggled onwards and upwards till a fresh social and political life had been organised. The second half of the M. A. may seem to lie in a dim twilight, but it is a twilight heralding the dawn, not passing into night: it is a dimness in which many glorious constellations are still visible—Aquinas, Bacon, Dante, Chaucer, and a host of lesser lights. Nor were these M. A. without their peculiar charms and gifts. They had their Chivalry (q. v.), Crusades (q. v.), and spirit of Romance, and in them architecture, with its handmaids, carving and glass-painting, attained a glory that has long since departed. There were night workers then who powerfully influenced succeeding generations—missionaries like Boniface and Methodius, who went forth to combat heathendom and slavery, the establishers of the hierarchic system and of feudalism, the inventors of gunpowder and the printing-press. See Hallam, *History of the M. A.* (1818); Rückert, *Geschichte des Mittelalters* (Stuttg. 1853); and Dr. L. Schmitz, *History of the M. A.* (Edinb. 1859).

Middlesbrough, the great centre of the iron trade in the N. of England, is situated in the N. Riding of Yorkshire, on the right bank of the Tees estuary, 6 miles from the sea, and 3½ miles E. of Stockton by the North-Eastern Railway. It owes its foundation to the formation of the Stockton and Darlington Railway, and to its advantages as a place for shipping coal. M. is the most remarkable instance of rapid growth among all the towns in England, its site being occupied by a single farmhouse in 1829. In 1831 the pop. was 383; in 1841, 5463; in 1851, 7431; in 1861, 18,992; in 1871, 46,643; and in 1874 it is estimated at over 60,000. In 1840 vast beds of iron were discovered in the Cleveland Hills, which run from the vicinity of M. to the coast at Whitby. The bed was 15 feet thick near M., and the quantity of ore raised in the Cleveland district in 1876 was 6,562,000 tons, the value being £1,162,020. Much smelting is carried on at M. and the vicinity, and the pig-iron manufactured in 1876 was 2,075,565 tons. Extensive steel works were opened in 1877. Besides pig-iron, the chief articles produced are finished iron in the shape of rails, ship-plates, iron pipes, girders, and heavy castings for bridges. Recently extensive Bessemer steel works were established by Messrs. Bolckow, Vaughan, & Co., the principal iron firm in the district, at Aston Junction, 2 miles from M., for the manufacture chiefly of steel rails from Cleveland and Spanish ores. Iron shipbuilding is an extensive industry (in 1876, there were built 11 vessels of 3897 tons), and there are large engineering and chemical works, potteries, saw-mills, tanneries, breweries, &c. In 1875 there entered the port 2051 vessels of 339,737 tons, and cleared 2988 of 536,641 tons. M. has several good buildings, a free library, a splendid new passenger station (N.E. Railway), and a public park, the Albert, of 72 acres, the gift of Mr. H. W. F. Bolckow, M.P. It was incorporated in 1853, and since 1868 has returned one member to Parliament.

Middlesex (originally the land of the Middle Saxons, those between the E. and the W. Saxons), the metropolitan county of England, lies on the N. bank of the Thames, between Essex on the E., Hertfordshire on the N., Buckinghamshire on the W., and Surrey on the S. Area, 282 sq. miles; pop. (1871) 2,539,765. Though, with the exception of Rutland, the smallest, it is next to Lancashire the most populous county in England. It has one court of general and quarter sessions, has 17 petty sessional divisions, contains 222 civil parishes, townships, and places, and returns 2 members to Parliament. It is watered by the Thames, Lea, Colne, Brent, and New River. The soil consists chiefly of London clay, and a large manufacture of bricks and tiles is carried on. Fruit and vegetables are abundantly cultivated, and cattle are reared for the supply of the London markets. The market towns, exclusive of the metropolis, are Uxbridge, Brentford, Southall, Staines, and South Mimms Barnet. Harrow and Enfield are also considerable places.

Middle Temple. See INNS OF COURT.

Middleton, an industrial town of Lancashire, and the terminus of a branch line of the E. Lancashire and Yorkshire Railway, 6 miles N.N.E. of Manchester. Silk weaving is the main industry, and there are large cotton mills, calico-printing

works, dye and bleaching works, iron-foundries, &c. In the vicinity are several collieries. *M.* has a free library and a weekly newspaper. Pop. (1871) 14,587.

Middleton, Conyers, D.D., a theologian of considerable ability, was born at Richmond, Yorkshire, December 27, 1683. He studied at Trinity College, Cambridge, of which he was elected a fellow in 1706. He first attracted notice by a series of pamphlets, in which, both on personal and public grounds, he vehemently attacked the famous scholar, Richard Bentley, then Master of Trinity College. In 1729 he published his *Letter from Rome*, denouncing the rites and ridiculing the miracles of the Romish Church. His greatest work, the *Life of Cicero*, appeared in 1741. Some of his later writings, such as *A Free Inquiry into the Miraculous Powers*, &c., and an *Essay on the Fall of Man*, were thought flagrantly unorthodox at the time. *M.* died July 28, 1750. His *Antiquitates Middletonianæ* (Lond. 1754) and *Miscellaneous Works* (4 vols. Lond. 1752-57) discuss points of theology and antiquities, and are not without value.

Middletown, a city in Connecticut, U.S., 24 miles N.E. of New Haven by rail, and 31 miles above the mouth of the Connecticut River. It has a fine custom-house, a Wesleyan College, an Episcopal College, ten churches, seven banks, and one daily and two weekly newspapers. Pop. (1870) 6923.

Middlewich, a market-town of Cheshire, England, in the basin of the Weaver, and on the Grand Trunk Canal, 17 miles N.W. of Stoke by rail. There are silk, cotton, and corn mills, and salt is made from several brine springs near the town. *M.* had its name from occupying the central position among Northwich, Nantwich, and the other salt-towns, or 'wiches,' a name applied to places producing salt, because that mineral was originally obtained by the evaporation of salt water in shallow bays (Norse, *wic*, 'bay'). Pop. of parish (1871) 4920.

Midge, a name popularly given to many *Dipterous* insects or Flies. Most of the typical midges belong to the family of the *Tipulidæ* or Crane-flies, of which the familiar 'Daddy Long-legs' is a good example. The common *M.* is the *Chironomus plumosus*. The larvæ are the little red worms so common in rain-water barrels, and in muddy waters. The larvæ of one species of *M.* (*C. oceanicus*) inhabits the sea. Two broods of these larvæ are produced in each season. Another genus of *Dipterous* insects which falls under the designation of *M.* is *Simulia*, of which *S. or Khagio Columbachensis* abounds in Hungary, and is known occasionally to kill cattle by its bite, and by suffocating them through gaining access in great numbers to the windpipe. *Simulia molesta*, the 'black fly' or black *M.*, is a common pest in America. All these insects have suctorial mouths, with certain parts modified to serve as a piercing apparatus for penetrating the skin of their victims.

Midhat Pasha, a Turkish statesman, was born in Constantinople in 1822. He entered the public service when very young, and held in succession various civil appointments. During the Crimean War he was sent to put down brigandage in Roumelia. He subsequently spent a few years in Paris, London, and other European capitals, where he imbibed a love of liberal institutions. In his first important office, governor of the vilayet of the Danube, to which he was appointed in 1864, he displayed ability and resolution, and encouraged improvements of all kinds. He afterwards became the leader of the Young Turkey party, and was appointed President of the Council of Justice. As a member of the cabinet of Mehmed Rushid he took a leading part in the deposition of the Sultans Abdul-Assiz and Murad. Early in 1876 he published a scheme of administrative reform, and on 19th December was created Grand Vizier, when he promulgated the new Turkish constitution. While advocating radical internal improvement, he was, however, vehemently opposed to foreign dictation, and was the soul of the Turkish resistance to the demands of the Constantinople Conference. *M.* was suddenly dismissed from his office and banished, February 5, 1877. Though he has since remained in exile, he is still the favourite statesman of the Ottoman people, and his recall to power is believed to be only a matter of time, should Turkey outlive the terrible assault now being made on her national life.

Midhurst ('the mid wood'), an old town of England, Sussex, on the Rother, an affluent of the Arun, 56 miles S.W. of London, and 6 W. of Petworth by rail. It is the polling-place for W. Sussex.

sex, and has a weekly market and three annual fairs. Here are the ruins of a castle of the Bohuns, where Edward VI. was entertained with great splendour. *M.* sends one member to parliament. Pop. (1871) 6753.

Mid'ianites were a nomadic tribe mentioned in the Bible, who seem to have dwelt principally in the desert N. of the Arabian peninsula, from the peninsula of Sinai (Exod. iii. 1) to the borders of Canaan (Numb. xxii. 4, 7; xxv. 6). The Semitic origin of the *M.*, and their consanguinity with the Israelites is acknowledged (Gen. xxv. 1), but they proved themselves troublesome neighbours to their kindred till they were quieted by Gideon (Judges vi.-viii.).

Midnapore, the chief town of the district of the same name, in Bengal, British India, on the left bank of the Cossye river, and the present terminus of the Iligh Level Canal, 68 miles W. from Calcutta. Pop. (1872) 31,491. It has manufactures of brass and copper ware, and conducts a large trade in rice.—The district of *M.*, which lies on the right bank of the mouth of the Hooghly, has an area of 5082 square miles; pop. (1872) 2,540,963. Near the sea it is very low, and liable to be flooded by cyclones. Here was formerly a flourishing salt manufactory, in the tract known as Hidgili. The rice crop is peculiarly abundant. In the interior the country rises into hills covered with jungle, where the tribe of Santhals collect lac, tussur silk, and beeswax. It was severely afflicted by the famine of 1866. There are now canals both for irrigation and navigation. The exports of rice, indigo, hides, oil-seeds, brassware, native cotton goods, and silk, are valued (1876-77) at more than one million sterling a year. Owing to the energy of the European magistrate, primary education has been very widely diffused.

Mid'rash (Heb. from *darash*, to study, expound, cf. 2 Chron. xiii. 22, xxiv. 27, 'story'), was among the Jews the science of studying and expounding the Holy Scriptures, the origin of which was co-eval with the return from the Babylonian Captivity, which was developed under the Great Synagogue (530-220 B.C.), and carried on by the Tanaim, or teachers of traditional lore (B.C. 220-220 A.D.). *M.*, meaning first of all expounding in the abstract, was applied next to the exposition itself (*pl. Midrashim*). It was thus the source of the Halacah (q. v.) and the Haggadah (q. v.), and of the innumerable commentaries and figurative expositions of the sacred text, which were at the same time called *M.*, although the name was by the people reserved for the more popular Haggadah. In short *M.*, in its widest sense, means the whole uncanonical Jewish literature, including the Talmud (q. v.), down to the 13th c., after which it ceased to be applied to Rabbinical writings. See E. Deutsch, *Lit. Remains*, Art. 'Talmud' (Lond. 1874).

Mid'shipman. According to the decision of the Board of Admiralty (January 1870), youths intended for the officering of the Royal Navy must after due examination serve two years on board a training ship as naval cadets, after which they are transferred to a sea-going ship. Those who have obtained first-class certificates are at once rated as midshipmen, but others have to serve from three to twelve months on the sea-going training ship before taking rank. Five years' service as cadet and midshipman is necessary before passing as lieutenant. A midshipman's pay is 1s. 9d. per day.

Mid'summer Day, the 24th of June, is the second of the English terms or quarter-days, on which rent falls due.

Mid'wife, Midwife'ry. Midwife (Old Eng. *maed*, 'a meed,' or 'reward,' and *wif*, 'a woman'), is the name given by the English to a woman who assists other women in childbirth, and its etymology indicates that her services were not gratuitous. From this is derived the term *Midwifery*, which designates the art or practice of assisting women in childbirth. For a male practitioner in this branch of the medical art the French term *accoucheur* is also used. Instead of the familiar designations, midwife and midwifery, the Latin terms *obstetrician* and *obstetrics* are sometimes used when applied to educated physicians.

In the great majority of cases parturition takes place naturally—that is, the child presents itself in the normal position, and delivery is completed within twenty-four hours with safety to the mother and child. In all cases some assistance is necessary, although not absolutely so, and hence the practice of *M.* has generally been confined to women. From the Old Testament Scriptures we learn that this was the custom among the Egypt-

tians and the Hebrews, and it is equally certain that it was so also among the Greeks and the Romans. Among all nations, and in all times, until very recently, women alone practised M. But while ordinary or natural cases were conducted by women, we learn that the Greek and Roman physicians were not ignorant of M., for Hippocrates refers to the necessity of turning the child in certain cases, and gives directions for the management of the placenta; and Celsus treats of the mechanism of parturition. Aëtius and Paulus Aegineta recommended the operation of craniotomy in certain cases. Rhazes advocated the rupture of the membranes when labour was impeded on account of their toughness, and Avicenna described an instrument somewhat resembling the modern forceps to be used in cases of prolonged labour. It would appear that the ancient physicians and surgeons did not attend ordinary cases of parturition, but only such as required operative interference. At about the commencement of the 16th c. the practice of M. appears to have become more generally recognised as a distinct branch of medical practice, and a work on the subject was published by Eucharius Rhodion, which was translated from the German into Latin, French, and English, and was the first book published on the subject in England. In 1573, Ambrose Paré, the celebrated surgeon, published a work on the subject, and in the early part of the 17th c., the *sage-femme* of Marie de' Médicis published a collection of observations on M. The greatest advance in the art of M. was made by the English obstetrician Chamberlen, at about the middle of the 17th c., by the discovery and the practical application of the forceps and the vectis. The form of the instrument used and its mode of application were not made public, and the exact nature of these instruments was not known till 1815, when a collection of obstetric instruments, including a double-bladed forceps and a vectis, now in the possession of the London Medico-Chirurgical Society, was discovered in a concealed space in a house occupied about a century before by Dr. Peter Chamberlen. In 1668, Mauriceau wrote a treatise on M., which was long a standard work, and which was translated into English, in 1672, by Hugh Chamberlen, and at about this time medical men began to engage generally in the practice of M. both in England and on the Continent. During the 17th c. midwives, in certain parts of Germany, used ergot of rye to accelerate parturition, but it was not till late in the 18th c. that the drug came into general use in M. practice. In the early part of the 18th c., Chapman taught M. in London, and was probably the first lecturer on the subject; and in the middle of the century a small hospital was opened by Sir Richard Manningham for the reception of parturient women; but, although several distinguished men practised obstetrics, as Smellie, Hunter, Denman, and Bland in this country, and Astruc and Baudelocque in France, the practice of M. was generally regarded as the lowest branch of the medical profession. During the present century great advances have been made in the science and art of M., and there are professors of, or lecturers on M. in all the medical schools; and attendance on a course of lectures, and an examination on the principles and practice of M. are necessary in order to obtain a medical qualification. There were formerly bye-laws which precluded practitioners in M. from the Fellowship of the London College of Physicians, but these have been repealed. Special provisions are also made for the education of midwives, and comparatively well-educated nurses are granted diplomas certifying that they have regularly attended lectures on M., and have gained practical instruction under qualified teachers. The passing of the Act of 1876, removing the disabilities as to sex for obtaining a medical qualification, will probably induce many females to study for the medical profession and devote their attention to obstetrics.

Midwifery.—M., as a branch of medical science includes, the study of the anatomy of the female organs of generation, the process of conception, the signs, symptoms, and duration of pregnancy, parturition in all its varieties, malformations of the pelvis, and the diseases peculiar to the puerperal state. While the majority of cases of labour are natural, unnatural labour may arise from malformation or disease on the part of the mother; or from abnormal conditions of the child, rendering manual or instrumental aid advantageous, or, in some cases, absolutely necessary to render delivery at all possible. In prolonged cases of labour, depending on atony of the uterus, or on obstructions in the soft parts, delivery by the forceps may be necessary without imperilling the life of either the mother or child; but the mechanical ob-

struction may be so great as to render the operation of craniotomy necessary, in which case the child is necessarily destroyed; or the Cæsarean section, whereby the life of the mother is in danger. In certain cases also, when the presentation is unnatural, manual interference is necessary, and if hæmorrhage be present instrumental delivery is also essential. Skilled supervision is also frequently necessary in the removal of the placenta, and for the arrestment of post-partum hæmorrhage. In Oriental countries and among savage and uncivilised tribes there must be great loss of maternal and infantile life in consequence of the want of skilled supervision during parturition; but, as a general rule, labour appears to be accomplished with less difficulty and with fewer complications among savage and semi-civilised tribes than among the highly civilised. See Leishman's *System of Midwifery* (Lond. 1876), and Playfair's *Treatise on the Science and Practice of Midwifery* (Lond. 1876).

Mignet, François Auguste Marie, a French historian, was born at Aix, in Provence, May 8th, 1796, where he pursued his studies in company with Thiers, both being called to the bar at the same time. In 1822 he published *De la Féodalité des Institutions de Saint Louis et de la Législation de ce Prince*. At Paris, besides contributing to the *Courrier Français*, he began a course of lectures, and in 1824 published the *Histoire de la Révolution Française* (10th ed. 1868), a work which is especially distinguished for the value of its political reflections. For the share he took in the journalistic protest against the decrees of July 1830, the new government rewarded him by the Directorship of the Archives of the Foreign Office. He became a member of the Academy in 1837, and upon the death of Comte, perpetual secretary for the Academy of Sciences. M. was removed from the Foreign Office by Lamartine in 1848, and since then his life has been one of quiet devotion to historical pursuits. Besides *discours*, *loges*, and *mémoires* relating peculiarly to France, M. published *Vie de Franklin* (1848), *Histoire de Marie Stuart* (1851; 3d ed. 1865); *Charles Quint* (1854; 3d ed. 1858), &c. His style is wanting in the lightness and buoyancy of the best writers; in narration he has not the rapid brilliancy of several contemporaries, but he is unexcelled in the philosophical summation of the aims and tendencies of historical events.

Mignonette, a diminutive of *mignon*, 'darling,' is the name given by the French to several favourite plants. In England (where the name has been in use more than 100 years) it is limited to the sweet-scented *Reseda odorata*, one of the best-known garden annuals, a native of the N. African coast countries. If protected in winter, and properly trained, the plant may be made to last several years, forming the tree-M. of gardeners. In early Roman times it held a high position as a charm for healing wounds. The genus *Reseda* numbers about thirty species, of which two are natives of Britain.

Migration of Animals, the phrase used to denote that peculiar feature of animal life, according to which certain animals are seen to pass with greater or less exactitude and regularity from one region or country to another, in conformity with the alternation of the seasons. The manner and details of this migration present some very inexplicable features. Some animals (e.g., swallows) pass from region to region in vast flocks: others singly and in a quiet, inconspicuous manner. Skylarks, according to Mr. St. John, arrive at first 'in a constant and straggling stream' on the coast of Norway, but later on, fly over in immense flocks. The male birds also usually arrive in the south, it may be days, or even weeks, before the females; whilst both sexes leave together on their southward journey. The question of the manner in which birds are enabled to find their way back to their own land, or indeed to travel unerringly between their temporary and permanent homes, is of an almost insoluble kind. Tegetmeier says that the 'homing' faculty of the carrier pigeon depends on a knowledge of landmarks—that is, on the sense of sight and on the 'instinct' of memory. But sight alone cannot aid birds while guiding their flight over, it may be, miles of sea, or over the whole breadth of a continent. Then again, the exact return of birds to their old haunts, is among the most wonderful of the phases of M. A pair of stone curlews have been seen to return year by year to a particular nest, notwithstanding the changed character of the surroundings—a former rabbit-warren in which the nest was placed having been converted into a plantation. Not less curious is the exactitude in point of time which marks the M. of many

birds. Many sea-birds (e.g., puffins) return to their haunts exact to a given day; and swifts disappear at a given time with the utmost regularity.

The causes of M., however, present points of the most interesting and intricate character. It would appear that the most feasible explanation that can at present be given of the M. of A. depends on the recognition of *inherited habits*, together with the presence of *physical or climatic change and geological alteration*.

Miguel, Dom Maria Evarist, ruler of Portugal from 1828 to 1834, third son of King João VI. and Carlota Joachima of Spain, was born at Lisbon, 26th October 1802, and in 1808 accompanied his parents to Brazil, where his education was neglected. He returned in 1821 to Portugal, where, under the direction of his ambitious mother, he placed himself at the head of the absolutist party, and in 1824 caused Marquis Loulé to be assassinated, the king at the same time being made prisoner in his palace. But, by the help of the French ambassador, Hyde-Neuville, the latter defeated the plot of M., who, with his mother, was forced to flee to Vienna. After the death of João VI., Dom Pedro, Emperor of Brazil, made over (2d May 1826) his right to the throne to his daughter, Donna Maria da Gloria, providing also M. should be made regent, and afterwards become her husband. M., however, on his return seized absolute power, dissolved (13th March 1828) the Constitutional Cortes, and caused himself to be proclaimed legitimate king on the 25th of June. He now gave himself up to every kind of tyranny and excess. In 1831 he had war with France, and suffered severely from the French fleet for his violence to French subjects, and soon after Dom Pedro returned to claim his daughter's rights. After three years' struggle he overcame M., who was exiled on the 29th May 1834. He went to Genoa, thence (1834) to Rome, married (1851) the Princess Adelheid of Löwenstein-Wertheim (born 1831), removed to Bavaria, and died at the castle of Brunnbach, near Wertheim in Baden, 15th November 1866. He left six daughters, of whom the eldest, Maria, married (1871) Alfonso, brother of the Spanish pretender, Don Carlos, and one son, M. (born 1853), who in 1874 announced himself as a claimant for the throne of Portugal.

Mikania, a large genus of *Compositæ* nearly limited to tropical America, where several species are in repute as a cure for snake-bites, and the native name of 'Guaco' has been botanically adopted for that considered most effective, namely, *M. Guaco*; but this valuable property has not yet been sufficiently authenticated by scientific experiment. Over a hundred species have been described.

Miklo'sich, Franz von, the greatest living Slavonic scholar, born at Lutzenberg, in Styria, November 20, 1813, was educated at Warasdin, Marburg, and Gratz, became in 1848 member of the Austrian Diet, and in 1849 Professor of Slavonic Languages at Vienna. M. has greatly benefited philology by a series of writings on the Old Church Slavonic, chief of which are *Kadices* (Leips. 1845) and *Lexicon Lingue Paleoslovenica* (Vienna, 1850), and *Vergleichende Grammatik der Slavischen Sprachen* (1852-74). He has edited the texts, *Vita Sanctorum* (Vienna, 1841), *Vita Sancti Clementis* (ib. 1850), *Codex Suprasliensis* (ib. 1851), *Apostolus monasterii Shishatovcensis* (ib. 1853), *Sancti Johannis Homilia in Ramos Palmarum* (ib. 1854), *Monumenta Serbica* (ib. 1858), and *Acta et Diplomata Græca Matii Evi* (1860-64). He has also written the important monographs, *Formenlehre* (Vienna, 1850), and *Lautehre der Altslovenische Sprache* (ib. 1850), *Ueber die Sprache der ältesten Russischen Chronisten* (ib. 1855), *Die Sprache der Bulgaren in Siebenbürgen* (ib. 1856), *Die Bildung der Slavischen Personennamen* (ib. 1860), *Die Slavische Elemente in Rumänischen* (ib. 1861), *Die Bildung der Ortsnamen aus Personennamen in Slavischen* (ib. 1865); and formed valuable collections in his *Slavische Bibliothek* (2 vols., ib. 1851 and 1858), and *Chrestomathia Paleoslovenica* (ib. 1854 and 1861). M. has of late years mainly devoted himself to the investigation of the Gipsy dialects, the results of his researches being embodied in *Die Mundarten und die Wanderungen der Zigeuner Europas* (Vienna, 1873-77).

Milan (Ital. *Milano*, Ger. *Mailand*), one of the largest and richest cities of Italy, and capital of the modern province of the same name, is situated in the plain of Lombardy, 71 miles N.N.E. of Genoa by rail. Surnamed 'the grand,' it is the seat of an archbishop, and a great manufacturing centre, occupying

a singularly advantageous position on the small but navigable river Olona. The town, following the line of its walls, ramparts, and canals, is about 7 miles in circumference. It is entered by some 12 gates, beyond which suburbs (*borghi*) have recently sprung up, taking their names from the gates. The chief of these is the Porta Venezia, at the end of the Corso Venezia, a handsome new prolongation of the principal street of M., the Corso Vittorio Emanuele. The great commercial centre of M. is the Piazza del Duomo, formerly the heart of a net-work of wretched lanes, now entered by wide handsome streets and enclosed by a new pile of fine buildings, and by the *Duomo* of M., next to St. Peter's at Rome the grandest and largest in Italy. It is built in the shape of a Latin cross, and in Gothic style, is surmounted by a dome 220 feet high, and by a tower of 360 feet, and is ornamented externally by 18 turrets, by 2000 marble statues, and by much exquisite carving. The interior is 159 yards long by 61 broad, and the nave, 155 feet high, is supported by 52 columns. Founded in 1386 by Gian Galeazzo Visconti, it was in part finished by 1500, but the great tower was added by Napoleon in 1805, and extensions and repairs have been going on ever since. One of the oldest churches in M. is that founded by St. Ambrose in 387, and dating in its present Romanesque form from the 12th c. It is rich in old tombs and frescoes, and is interesting as the place where the Lombard kings and German emperors were crowned with the iron crown that has been preserved, since the time of Barbarossa, at Monza. Other notable churches are the Gothic S. Maria delle Grazie of the 5th c., containing Leonardo's 'Last Supper'; S. Lorenzo, the oldest in M., founded in the 4th c., and enriched with mosaics of the 6th and 7th centuries; S. Eustorgio, which was rebuilt in 1278, and contained the 'bones of the magi' prior to 1162; and S. Alessandro (1602), the most splendidly decorated church in M. The famous Brera or Palazzo delle Scienze ed Arti, formerly a Jesuits' college, comprises a very valuable picture gallery of 800 works, the library of the Academy, founded in 1170, and containing 200,000 vols., a collection of 50,000 coins, an archaeological museum, and the observatory. M. is singularly affluent in art and literary treasures. The Biblioteca Ambrosiana, founded by Cardinal Borromeo in 1609, now contains 140,000 printed vols., and 20,000 MSS. and palimpsests. The Pinacoteca counts among its priceless works many rare specimens of Raphael, Leonardo, Titian, &c. Besides other public collections, M. can boast of 26 private picture galleries, while it has also 15 museums of natural history, and 14 of medals and antiquities. Perhaps the principal modern secular building is the Galleria Vittorio Emanuele, the largest and finest arcade in Europe, surmounted by a cupola 180 feet high, lighted in the evening by 2000 gas-jets, and erected (1865-67) at a cost of £320,000. Foremost among its many splendid charities, is the Ospedale Maggiore, one of the largest hospitals in the world, founded in 1457, and relieving yearly some 20,000 patients. M. holds a high rank as an educational centre, having celebrated schools of medicine, of music, of military science, in addition to its gymnasias and its many normal, technical, and conventual schools. Of the numerous places of amusement in the so-called 'Little Paris,' the chief is the theatre of La Scala (1778), after San Carlo at Naples the largest in Italy, holding 3000 persons. The old and new public gardens afford delightful promenades, and in the N.W. of the city extends the Piazza d'Armi, with an area of 783 by 748 yards. The fine new Cimitero Monumentale, outside the Porta Garibaldi, has an area of 500 acres, and cost the city, exclusive of the price of the ground, 1,000,000 francs. A Tempio di Cremazione, for the burning of dead bodies, was added to it in 1876. The manufactures of M. are silks, woollens, ribbons, porcelain, cutlery, &c., &c. Pop., with the district of Corpi Santi (1874) 199,009. M., the ancient *Mediolanum* ('middle marsh land'), was the largest town of Cisalpine Gaul, when taken by the Romans in 222 B.C. Cicero and Marcus Brutus were among its governors, and for wealth and influence it almost rivalled Rome in the 3d c. Maximian, in the 4th c., made it the imperial residence. It was early Christianised, but was sacked by the Huns in 452, and by the Goths in 539. Its struggles against the empire were ended by Friedrich Barbarossa, who totally destroyed it in 1162. Subsequently it was governed by the Visconti (q. v.), and by the Sforza (q. v.), and during the supremacy of the latter (1447-1535) it rose, by its patronage of art, to the zenith of its fame. It was the residence of Bramante, of Leonardo da Vinci, and of his many illustrious disciples. After several

political vicissitudes, M. eventually fell to Austria in 1714. In 1796, Napoleon made it the capital of the Cisalpine Republic, and finally of the 'kingdom of Italy.' It was restored to Austria in 1815, but after the Franco-Austrian War of 1859, it was annexed with the rest of Lombardy to Sardinia, and once more became Italian.

Milan IV. Obrenovitch, Prince of Servia, born at Jassy, 22d August 1854, is the grand-nephew of Milosch Obrenovitch (q. v.), founder of the reigning dynasty. His father, only son of Prince Ephraim, was married to a Moldavian lady. Adopted by the childless Michael III., the young M. was sent for education to Paris in 1864, but was recalled by the Skuptchina to occupy the throne in 1868 on the assassination of Michael. M. was crowned at Belgrade on attaining his majority in 1872, and married Natalie Keschko in 1875. In June of the latter year Servia joined Bosnia and Herzegovina in the revolt against the Porte, but in a brief campaign the Servians, in spite of the help rendered by an organised force of Russian volunteers, were repeatedly beaten by the Turkish troops, till finally the storming of Alexinatz, on the 1st September, opened the way to Belgrade, and thus placing Servia at the mercy of her opponent, compelled M. to sue for peace. The settlement of the terms of peace directly involved the interference of Russia, and led eventually to the Conference at Constantinople. At present (October 1877) great efforts are being made by Russia to induce Servia to join the Slavic crusade against the Ottoman.

Milazzo, a fortified seaport of Sicily, in the province of Messina, stands on the narrow neck of the Capo de M., 20½ miles W. of Messina. It has a fine harbour, capable of admitting ships of war, and a castle, erected by Karl V., and restored in the 17th c., now converted into a prison. There are valuable tunny fisheries, and an export trade in oil, wine, linseed, dried fruits, &c. Pop. (1874) 12,060. M. (the *Myle* of Strabo) was founded by the Zancleans prior to 648 B.C., surrendered to the Athenians under Laches (427 B.C.), and after the Roman conquest of Sicily enjoyed the privileges of a *federata colonia*. The Consul Duilius gained the first Roman naval victory in the Bay of M. (260 B.C.); and here Garibaldi with 2500 men defeated 7000 Neapolitans under General Bosco, July 20, 1860.

Mildew (Ger. *mehlthau*, 'meal- or flour-dew') is a name descriptive of the powdery appearance upon the leaves and the stems of plants from the growth over their surface of certain minute fungi; but at the present day the term has been extended to the dark mildew of the wheat, or even to cases in which no parasitic fungus is present. In the hop M., the rose M., the M. of peaches and of grapes, the white mealy coating represents the young state of the fungus, the perfect form being some *Erysiphe* or closely allied genus, and it may be conquered by dustings with sublimed sulphur. The wheat M., arising from a species of *Puccinia*, is at present without any known remedy. The dark spots found on linen after being folded up for a time in a damp place are attributable to M., which however may originate from impure starch used in the dressing of the goods.

Mile (Lat. *mille passuum*, 'a thousand paces'), the standard itinerary measure used in most European countries. The English statute mile was defined by an Act passed in the reign of Elizabeth as equal to 8 furlongs of 40 perches of 16½ feet each; and is, therefore, 5280 feet, or 1760 yards. The Roman pace was 5 feet, and the foot was 11⁄162 English inches; so that the ancient Roman mile was 1614 English yards. The value of the mile varies much in different countries, owing probably to the early confusion of the Roman measure with the Celtic league. In France the old league has been abolished, and has given place to the kilomètre (see METRIC SYSTEM). Taking the English statute mile as unity, the values of the most important European miles are as follows:—Modern Roman mile, .925; Tuscan mile, 1.027; Spanish league, 4.151; Portugal mile, 1.278; German mile, 4.604; Danish mile, 4.681; Swedish mile, 6.648; Swiss league, 2.983. In Portugal, Spain, Germany, and Italy, the metric system has been established by law, and the adoption of the same by other countries is only a question of time.

Miletus, once the greatest of the thirteen cities of the Ionian League, stood on the peninsula of Grion, at the southern entrance of the Latmicus Sinus, about 25 miles S. of Ephesus. Its site has now receded 10 miles from the coast. According to tradition, M. was originally a Carian town, and was captured by

the Ionians (circa 1043 B.C.), under whom it speedily attained a high commercial prosperity, being famed for its woollen manufactures, and planted colonies on the shores of the Euxine, Hellespont, and Ægean. It became tributary to Croesus, was sacked by Darius (494), and remained subject to Persia till the battle of Mycale (479), when it joined the Athenian Confederacy. It was stormed by Alexander the Great (334), sided with the Romans against Antiochus, was visited by St. Paul (60 A.D.), and was finally destroyed by the Turks. See Leake's *Asia Minor*, p. 239.

Milford, a seaport of S. Wales, in the county of Pembroke, is situated on the N. shore of the famous haven of the same name, 7 miles S. by W. of Haverfordwest, and 6 W. by N. of Pembroke, with which it is connected by rail. It has extensive and recently-constructed harbour works, a considerable coasting-trade, chiefly in coal, and a productive oyster fishery. *M. Haven*, one of the finest natural harbours in the world, is 17 miles long and 2 broad, is about 19 fathoms deep, and is sheltered by a circle of low hills. Prior to 1814 M. was the seat of a royal dockyard and arsenal, and a station for the Irish mail-packet. Although a thriving port from the earliest times, it still remains imperfectly developed in regard to the rich mineral resources of the neighbourhood, and its splendid access by sea. In 1875 there entered the port 1262 vessels of 263,804 tons, and cleared 1173 of 228,030 tons. Pop. (1870) 2836. The village of New M., 3½ miles to the E., has taken some of the trade from the older port, and is in regular steam communication with Waterford, Bristol, Liverpool, &c.

Military Frontier (Ger. *Militärgrenze*), a long, narrow strip of land on the boundary of Austria with Turkey, which gradually received a military organisation for the resistance of sudden inroads by the Turks, the prevention of smuggling, and the exclusion of contagious disease. A number of families ('Grenzhäuser') were originally privileged to occupy a certain area, on condition of rendering military service when required against the Turks. After the danger of Turkish invasion had, at the end of the 17th c., practically ceased, a movement was made to put the M. F. on a civil instead of a military footing, but the attempt cost several civil envoys and commissaries their lives, and the military organisation not only remained in force, but was even extended. The proceeds from the lands assigned to a family are divided equally among its members, except that the 'Hauvater' and 'Hausmutter' each receive a double share. Besides this estate, or 'Stammgut,' which cannot be sold, the family is at liberty to acquire allodial property, or 'Ueberland.' The different 'Grenzhäuser' are classed under 'Grenzcommunionen,' from which are formed 'Compagnien' and 'Regimenter.' The inhabitants of the twelve towns called 'Militärcommunitäten' undergo lighter service, and have a more restricted right to hold any portion of the M. F. In 1849 the M. F. was declared an independent crownland, and in 1850 the inhabitants were invested with the ownership of the lands which they had previously only occupied, but in the following year the Transylvanian portion of the M. F. passed under civil government. From the latter year till 1871 the M. F. was divided into two sections, governed respectively from Agram and Temesvar, the Croatian-Slavonian and the Servian-Banatic, the former comprising 10 regiments and 7 military communities, the latter 7 regiments, 1 battalion, and 5 communities. The whole district, from the Adriatic to the W. boundary of Transylvania, had an area of 2800 sq. miles, with about 1,200,000 inhabitants. Since 1871 the so-called Warasdin Frontier, consisting of two regiments, has been incorporated with Croatia and Slavonia, which it formerly separated, and the Servian-Banatic Frontier has been joined to Hungary. Thus, of the former M. F. there remains only the W. part, stretching from the Adriatic to the junction of the Drina and Save, with an area of 1320 sq. miles, and a pop., almost all of Slavonic stock, numbering (1869) 593,232, of whom 319,000 are Catholics, and 266,000 belong to the Greek church.

Military Immunities. A soldier in the regular army has certain civil privileges. He cannot be punished for leaving any work or employer, nor can he be summoned or arrested for a debt under £30. See MUTINY ACT.

Military Secretary, a confidential officer on the personal staff of a general, with whose correspondence he is intrusted.

The M. S. of a general in the field has £346, 15s. a year, but that at the Horse Guards receives £2000. A general of division may have an assistant M. S. with a salary of £173, 7s. 6d.

Militell'o, a town of Sicily, province of Catania, in the rich corn-land of the Val di Catania, 17 miles E. by N. of Callagirono. Pop. (1874) 9875.

Militia (from Lat. *miles*, 'a soldier'), an organisation apart from the regular army of a country, which may in certain cases be called out for military purposes. In England a force of this kind has existed from a very early period. Before the Norman Conquest every five hydes of land were charged with the equipment of one man, and freemen were, according to their wealth, obliged to provide arms, which could not be sold or pledged, and required to be annually exhibited. After the Norman Conquest this force, called 'the Fyrd,' was maintained in addition to the feudal army, supplied by the barons and knights in exchange for the land held by them. The scale of arms assigned to each class was revised in 1285, but the regulation as to keeping of arms was not abolished till 1604, when James I. raised his 'train bands.' No man in the M. was liable to be sent out of his county, save on great national emergencies. The command was vested in 'commissioners of array.' In the reign of Charles I., Parliament insisted on its claim to appoint commissioners, and the king refusing his consent, the civil war took place. On the Restoration the M. was reorganised, the supreme command being vested in the king, and under him in the lord-lieutenant of each county, and the inhabitants were compelled to contribute to its support. A bill to reconstruct the M. was passed in 1757. All able-bodied men from eighteen to thirty-five, with the exception of certain ranks and trades, were liable to be selected by ballot for five years' service. The enforcing of the ballot produced rioting, and has never been much resorted to, the numbers having been usually adequately supplied by voluntary enlistment. A balloted man had to serve himself, produce a substitute, or pay a fine. A supplementary force of M. was raised in 1790-1799. In 1797 a bill ordered the formation of M. in Scotland. From 1817 to 1852 the ballot was wholly suspended. Under Lord Cardwell in 1872 the control of the M. was transferred from the lord-lieutenants of counties to the war office, and a certain number of M. regiments (usually two) were under the new army organisation attached to each brigade of infantry, under command of the colonel of the military district. Barracks were erected for their monthly training at the district depots. In Mr. Gathorne Hardy's Mobilisation Scheme of 1876, the place where each regiment would be sent in case of invasion was assigned, the force having been liable since 1859 to serve in any part of Great Britain. The M. has been embodied on the following dates, 1757-1763, 1778-83, 1792-1803, 1815, 1854, and 1857. It has always been practically the feeder of the army. In one year alone (1799) 25,000 men volunteered as regulars. The battle of Talavera was won principally by drafted militiamen. Fifty regiments volunteered for foreign service during the Crimean War, and ten of these were sent to Mediterranean stations. Eighteen regiments volunteered in the same way during the Indian Mutiny. A M. reserve, not to exceed in number one-fourth of the M., was created by Act of 1867, consisting of men actually serving in the M., who receive an additional bounty of £1, and in time of war may be drafted into the army. Officers of the M. who have had two years' training may obtain commissions in the regular army on passing an examination. The pay of the M. is nearly the same per day as that of the infantry of the line. The pay and allowances, amounted in 1875-76 to £685,300, and the total charge for effective and non-effective services was £1,214,153. The strength of militia and infantry was 133,952. See the *History of our Reserve Forces* (Lond. 1870).

Laws affecting the M.—By 15 and 16 Vict. c. 50, the Acts relative to the M. in England are consolidated and amended, and a M. force of 80,000 men is now immediately available, which may in an emergency be raised to 120,000. The Act provides for voluntary enlistment for five years, and authorises a bounty not exceeding £6 to be paid to each person enlisting. The period of training and of exercise are not to exceed twenty-one days in one year, unless extended by order in council. The quotas for each county are fixed by order in council, and where the quota has not been enrolled by voluntary enlistment, the Queen in council may order the deficiency to be raised by ballot.

The M. may now be called out during war, or in case of national danger. By 17 and 18 Vict. c. 105, innkeepers and others are made liable to have the permanent staff of the M., when disembodied, billeted upon them. 22 and 23 Vict. c. 38, regulates the interchange of M. between England and Ireland, and the periods of service. The M. in Scotland is now regulated by the Act 17 and 18 Vict. c. 106.

Milk (Old Eng. *meole*, Ger. *milch*, from *melken*, 'to handle,' allied to Lat. *mulgere* 'to milk,' *mulcere* 'to soften,' and Gr. *amelkein* 'to squeeze') is the fluid secretion with which all mammalian animals suckle their young. It is an opaque, white liquid with a slightly yellowish tinge, and seen under the microscope it consists of a congeries of minute globules of fat, to which the white colour is mainly owing, with still smaller globules of nitrogenous matter, all floating in a watery fluid. M. being the only food supplied to the young of the most highly organised creatures is found to contain all the essential ingredients of a perfect dietary, and is therefore regarded as a typical food. The fatty globules above mentioned, by virtue of their superior specific gravity, gradually rise to the surface when M. is allowed to settle, and form Cream (q. v.), from which Butter (q. v.)—the fat of M.—is prepared. M. contains a second carbohydrate, in the form of lactose or milk-sugar, which gives to the substance the sweetness it possesses. By fermentation or souging, the lactose is converted into lactic acid, which causes the nitrogenous constituent of M.—casein (see CHEESE)—to coagulate, and the M. therefore thickens. In the process of making cheese, the butter and casein are removed by artificially coagulating the M., and the fluid yellow whey which remains consists of water, with the lactose or milk-sugar, the most of the salts which are present in M., and some traces of fatty and nitrogenous matter unremoved. M. forms an exceedingly valuable article of food to adults as well as infants throughout the entire world, and as the source of butter and cheese it is the basis of most important and valuable industries. The M. chiefly employed as an article of adult food is that of the cow, but goat's M. is also frequently used. Sheep's M. is common in the N. of Europe, and is the basis of the celebrated French Roquefort cheese; the Laplanders use reindeer's M., the Tartars consume the M. of the mare, and prepare a fermented liquor called Koumiss (q. v.) therefrom; and among the Arabs camel's M. is used. Human M. contains less fat and casein, but more sugar than that of the cow. The following table exhibits the average composition of the principal varieties of M.

	Human.	Cow.	Ass.	Mare.	Goat.	Sheep.	Pig.
Water,	89.0	87.3	88.7	89.3	86.4	83.8	84.8
Casein, &c.,	1.6	4.1	2.4	2.1	4.8	5.8	4.3
Butter,	2.1	4.7	1.5	1.6	4.2	4.0	5.0
Milk-sugar,	6.9	5.1	7.1	6.1	4.1	4.8	5.7
Milk-in matter,	0.2	0.8	0.3	0.4	0.5	0.8	0.8

The M. of cows though remarkably constant in its constitution on the whole, varies within certain narrow limits, according to the breed, state of health, food, and age of the cow yielding it. Thus some breeds—the Alderney cattle, for example—yield only a small quantity of M. very rich in fat, while other breeds, such as the long-horns, give more M., and that proportionally richer in casein. A cow yields on an average from 20 to 25 pints of M. per day, of which about 12 per cent. is cream; but as much as 40 per cent. of cream is sometimes obtained from the M. of an Alderney cow. *Skim M.* consists of M. deprived of a large proportion of its cream by skimming, but as it still retains nearly all its casein and other constituents, it is a valuable and nutritious food. *Butter M.* is the caseous portion of cream from which the butter has been separated by churning. Condensed M., now in extensive use, is sweet milk partially evaporated by steam heat, and thickened with sugar. The adulterations to which M. are subject consist almost exclusively in the fraudulent abstraction of cream, and in adding water to the M.

Milk Fever. When the milk is being first secreted the mammary glands are in a state of great activity; but occasionally this excitement is excessive, and a high degree of fever accompanies the newly established action. M. F. is most frequent after a first birth, and is ushered in by shivering, headache, hot skin, quick pulse, and the principal features of pyrexia, together with pain, tumefaction, and hardness of the breasts. Sometimes M. F. is followed by inflammation and abscess of the mammary glands. The best prevention of M. F. is the early

application of the infant to the breast; and, when the fever has set in, it is best subdued by emptying the breast, and by the administration of aperient and saline medicines. The patient should be kept upon a low diet for a day or two, and local inflammatory symptoms should be controlled by appropriate means.

Milk Vetch. See *ASTRAGALUS*.

Milk Wort. See *POLYGAIA*.

Milky Way (*Via Lactea*), also known as the Galaxy, forms a well-marked zone of light in the night sky. Though very irregular in its outlines, it can be traced right round in a great circle, inclined to the celestial equator at an angle of about 63° , and intersecting it in the constellations Monoceros and Aquila. For nearly half its length it is composed of two branches; while as it passes through the southern cross it becomes very narrow, but at the same time very intensely luminous. Its true nature was indicated by Galileo; but most of our knowledge we obtained from the researches of Sir William Herschel—at once the pioneer and prince of star-gaugers. By means of his magnificent telescopes, he completely resolved the M. W. into its component stars. Not only so, he speculated upon the probability that the M. W. formed a gigantic cluster of stars, of which our sun was one. The section of this cluster, by a plane drawn through the sun at right angles to the plane of the M. W., would have a shape something like the letter Y with the sun about the point of bifurcation. This hypothesis explains all the leading phenomena—such as the two branches, and the comparative absence of stars on other parts of the heavens. Struve's researches led in the same direction. If the M. W. were viewed from a far distance in the line through its centre perpendicular to its plane, it would no doubt present an appearance like some of our irresolvable nebulae. These nebulae may then be great clusters of stars similar to our M. W., but at such an inconceivably great distance, that as a rule they are only visible as faint hazy luminosities with the strongest telescopic power at our disposal. See *NEBULA*.

Mill (O.E. *ling. miln*, Ger. *mühle*, allied to Gr. *mylē* and Lat. *mōla*, 'a mill,' from *molere*, 'to grind'), a term applied to a machine for grinding or pulverising any substance by means of two inclined or grooved surfaces, between which the substance is placed. The earliest kind of M. was that used for comminuting corn, and in its original form it resembled a rude kind of mortar. A corn-mill of this sort is still found in use among African and other degraded tribes. In process of time millstones in the form of two circular stones, placed one on the other, were substituted. The upper stone rotates on a pivot on the under or nether stone, which is fixed; the adjacent faces are grooved radially with furrows, and in the centre of the upper stone there is an aperture for the introduction of the grain, which is thrown off as flour at the edges. For the better distribution of the grain between the stones, the grinding surface of the upper one is made slightly concave around the central aperture. The upper stone was originally moved by hand, and afterwards by cattle; water-power was employed by the Romans, while in modern flour-mills steam is used. Millstones are composed of hard silicious vesicular rock, obtained in unrivalled quality at La Ferté-sous-Jouarre, in France, and are formed of segments (Fr. *moulaux*), cemented and bound round the circumference with iron bands. The common diameter of a millstone is 4 feet, and the thickness 12 inches, part of which consists of concrete or plaster of Paris, and burrstone chips, by the use of which the necessary weight is secured and expense saved. The sharp edges which crush the corn are soon worn smooth, and the stones therefore require frequent re-dressing. Under the head *DISINTEGRATOR* a most useful and effective form of M. is described. Disintegrating flour-mills on the same principle, but with more cages, usually eleven, of steel bars, are extensively employed. Three or four pairs of ordinary millstones are used to grind the semolina produced in one of these disintegrating flour-mills, which, however, perform as much work as twenty-seven pairs of millstones would do; the saving of space thereby effected is therefore very great.

There are many other forms of M. with a crushing and grinding action used in industrial pursuits—as, for example, paint-mills, mortar-mills, ore-mills, &c. A revolving iron pan or trough, with two heavy vertical rollers at the extremities of an

axle placed in it, is found very effective for grinding the ingredients of mortar. For working clay, a machine called a *pug-mill* is employed. It consists of a cylinder with a central shaft fitted with knives which thoroughly incorporate the clay in its passage through the machine. Various other kinds of machinery are denominated mills, and the term M. is also generally applied to places where raw materials are brought into a condition for use. Thus, there are saw-mills, powder-mills, oil-mills, mills for the manufacture of textile fabrics, wind-mills, water-mills, &c. *Millwork* is the name given to the combination of machinery for the transmission of power in a manufacturing mill or factory. For practical details, see Sir W. Fairbairn, *Mills and Millwork* (2 parts, Lond. 1861-65); R. Buchanan, *On Millwork and other Machinery* (by Tredgold and Rennie, 1841-42); T. Box, *Practical Treatise on Mill-gearing* (1809).

Law Regarding Mills.—A proprietor of an upper portion of a stream which drives a M. is not entitled to alter its course or to diminish its volume to the injury of the M. Under 24 and 25 Vic. c. 97, to destroy the dam of any millpond subjects the offender to penal servitude for a period not exceeding seven years.

Mill, James, was born at Northwater Bridge, near Montrose, in Forfarshire, 6th April 1773, educated at the parish school and at Montrose Academy till the age of eighteen, and then sent by the help of the family of Stuart of Fettercairn to the University of Edinburgh, where he became the pupil of Playfair and Donald Stewart, and afterwards passed through a complete course of Divinity. In 1798 he was licensed to preach; but his preaching is said by Sir David Brewster to have been very bad. During this time M. acted as tutor to Miss Stuart, afterwards the mother of James David Forbes, the naturalist, and in the family of Burnett of Ellick (Aberdeen). Beaten by Sir David Brewster's brother in a candidature for the parish of Craig, M. went to London in 1802, and began work for John Gifford of the *Anti-Jacobin Review*, and for the *Encyclopædia Britannica*. He also became editor of the *Literary Journal* and of the *St. James's Chronicle* newspaper. In 1805 he married Harriet Burrow, whose mother kept a private lunatic asylum at Hoxton. By her he had nine children (the eldest John Stuart), of whom four daughters survive. The next 10 years were devoted mainly to the *History of British India* in 6 vols. The history, which still remains, the best work of the kind both in accuracy, clearness, and adherence to sound principle, obtained for him the post of Assistant Examiner of India Correspondence from the Court of Directors, which he held till 1832. Before his appointment he had contributed to the supplement of the 5th edition of the *Encyclopædia Britannica* his classical articles on Government, Education, Colonies, Prison Discipline, Jurisprudence, Law of Nations, Liberty of the Press, which are also published separately. To 1822 belongs his *Elements of Political Economy*, a work much more accurate than Malthus and more popular in style than Ricardo. To 1829 belongs his *Analysis of the Phenomena of the Human Mind*, which in absolute clearness of statement resembles Hobbes or Comenius, but which avoids the greater fallacies of the extreme sensational school. The careful posthumous edition of this in 1869 by his son, Prof. Bain, and Dr. Emilsson is probably the best Manual of Psychology (from the mental side) in English. It proceeds entirely on the principles of association as affecting the individual, and does not allow for the inherited experiences of the race. M. supported the Ballot and other reforms in the early numbers of the *Westminster Review*. At the house of Bentham, to whom M. owed much help, he formed the school of Philosophical Radicals (Grote, Roebuck, Baines, John Stuart Mill, &c.), who may be said to have directed the important legislation of this country for the last forty years. His latest work, *Fragment on Mackintosh* (1835), is a criticism almost amusing, in its grim energy of destruction on Sir James Mackintosh's wordy and superficial *Dissertation on the History of Ethical Philosophy*. M. died at Kensington, 23d June 1836. He was a man of great energy of character and acuteness of mind, striving amid much discouragement for a lofty intellectual ideal; but he was harsh and unlovable, even to his children. — **John Stuart M.**, eldest son of the preceding, was born at London, 20th May 1806. The story of his rigid education has been told in his posthumous *Autobiography*. A journey to France, where he saw J. B. Say and lived with Sir Samuel Bentham, began his lifelong familiarity with things French,

which may be distinctly traced in the lucidity, point, and balance of his style, especially in animated passages. He spent thirty-five years in the service of the East India Company, retiring in 1858 when the territories were transferred to the Crown. All this time, however, his life was full of practical and speculative interests. As a philosophical Radical he supported the cause of Reform in the *Westminster* and *London Review*, announcing principles which were afterwards more fully stated in such works as *Liberty* (1859), *Considerations on Representative Government* (1861), *Subjection of Women* (1869), and the more directly political portions of *Principles of Political Economy* (1848). He preached the doctrine of individualism, or free development of social units, as a necessary condition of social welfare. In the *Unsettled Questions of Political Economy* (1844), and the larger work just mentioned, he states the doctrines of capital, wages, rent, profits, international values, currency, &c., in extremely popular and yet precise language; and he discusses the limits of government interference and other political questions with extensive knowledge of previous discussions and of the actual condition and experience of foreign states. His *System of Logic* (1843) is the most important treatise on that science written by any Englishman in modern times. His chief contributions to philosophy proper were *Utilitarianism* (1862), a re-statement of Bentham's principles, with some modifications; and his trenchant *Examination of Sir William Hamilton's Philosophy* (1865). As a disciple of the Experience or Association School, he of course attacks the Hamiltonian doctrines of the Unconditioned, Free Will, Cause and Perception, but he also professes to have discovered glaring contradictions in the characteristic theory of Natural Realism. M.'s writings on general subjects have been collected in 3 vols. of *Dissertations and Discussions* (1859). M.'s ardent political convictions led him to the House of Commons, where he sat for Westminster from 1865 to 1868. His name is associated with the Women's Suffrage movement. He died at Avignon, 8th May 1873. M.'s influence on at least one generation of his fellow-countrymen was immense. His works are still studied by all classes. Democratic in politics, agnostic in religion, and opposed to intuitionism in mental science, he represents many of the currents of thought in the latter half of the 19th c. The posthumous *Autobiography* (1873) and *Essays on Nature, The Utility of Religion and Theism* (1874), have not altered the general effect of his writings. In 1873 appeared an interesting memorial, consisting of twelve distinct sketches of M. and his work, by Fox Bourne, Herbert Spencer, J. E. Cairns, Henry Fawcett, and others.

Millais, John Everett, R.A., an English artist, was born of an old Jersey family at Southampton, 8th June 1829. He entered the Academy in London at the age of eleven, and his first important picture was 'Pizarro seizing the Inca of Peru,' exhibited at the Academy in 1846. This was followed by 'The Widow's Mite,' a colossal cartoon (1847), and 'The Tribe of Benjamin seizing the Women of Shiloh' (1848). In 1849, together with W. Holman Hunt and D. G. Rossetti, he renounced the teaching of the Academy and the traditions of 'the antique,' and became one of the founders of the so-called 'Pre-Raphaelite School,' which subsequently received the enthusiastic support of Mr. Ruskin, expressed in letters to the *Times* (1852), in a pamphlet on *Pre-Raphaelitism*, and in his *Lectures on Architecture and Painting* (1853). The chief works produced by M. under this new influence were 'Isabella' (1849), 'Ferdinand cured by Ariel' (1850), 'Mariana in the Moated Grange' and the 'Woodman's Daughter' (1851), 'The Huguenot' and 'Ophelia' (1852). He became Associate in 1853, and R.A. in 1863. Among his later works are 'The Order of Release' (1853), 'The Rescue' (1855), 'A Dream of the Past' (1857), 'The Black Brunswicker' (1861), 'Joan Darc' (1865), 'A Souvenir of Velasquez' (1868), 'The Knight-Errent' (1870), 'Moses' (1871), 'New-Laid Eggs' (1873), 'A Day Dream' (1874), 'The Sound of Many Waters' (1877). Several of these pictures, especially 'Isabella' and 'The Huguenot,' are widely known through engravings. They are all more or less characterised by vivid realism, a masterly breadth, combined with affectionate minuteness, a classic simplicity of design, and pure radiant colouring.

Millau, or **Milhau**, a town of France, department of Aveyron, on the Tarn, 40 miles S.E. of Rodez, has large tanneries and manufactures of gloves, silk, and draperies, and carries on

a trade in wood, wool, and 'Roquefort cheeses.' It was a stronghold of the Calvinists in the 16th c., but was dismantled by Louis XIII. (1629), and suffered greatly from the revocation of the Edict of Nantes. Pop. (1872) 13,804.

Millboards are strong and flexible boards, made like brown wrapping-paper from old tarred rope and coal sacks. They take their name from the fact that in the finishing process they are 'milled' under heavy rollers, to impart solidity and a smooth surface. They are made of various thicknesses and sizes for use by trunkmakers, vellum binders, and bookbinders.

Millennium (Lat. 'the space of a thousand years'), is the name applied, owing to the duration generally assigned to it, to the Messianic kingdom of heaven or of God, which the first Christians expected to be established upon the earth by Christ at his second advent, and which has been looked for by many Christians down to the present time. The ideas regarding it were borrowed from the Jews. It was a prevailing belief among the latter before and at the time of the coming of Christ that the Messiah would establish a glorious and universal kingdom at Jerusalem, all nations being either reduced to subjection or destroyed, the Jews gathered from the ends of the earth, and the Temple restored. As to the duration of this kingdom, the prevalent belief was that it was to be eternal (cf. John xii. 34); but other opinions were that it would last 40, 70, 400 (2 Esd. vii. 28), 1000, and several thousand years. The authority adduced for the 1000 years was Is. lxiii. 4, interpreted by Ps. xc. 4 (cf. 2 Pet. iii. 8). The narrative of the creation of the world (Gen. i.) was also regarded as a type of its destinies, and hence it was concluded that as God had created the world in six days and then rested on the seventh, so the world would be completed in 6000 years (according to Ps. xc. 4, as above), and the seventh thousand would be a time of rest and Messianic bliss. Again, at the coming of the Messiah, there was to be a resurrection of the dead (Dan. xii. 2), and in the later Jewish theology the resurrection spoken of by Daniel became twofold; (1) of the pious at the appearing of the Messiah, to take part with him in his kingdom; (2) a general resurrection at the last day, for universal judgment.

The early Christians, finding themselves in circumstances of trial and adversity, similar to those of the Jews, and doubtless also, in the case of the Jewish Christians, from Jewish training and traditions, adopted their hopes for the future, and looked forward to the time when the true Israel of God would come triumphant out of their conflicts, and attain to the dominion of the world. This was to take place at the second coming of Christ, which in many passages of the New Testament is represented as near at hand (cf. Matt. x. 23, xvi. 27, 28, xxiv. xxv.; Mark xiii.; Luke xxi.; Rom. xiii. 11, 12; 1 Cor. vii. 29, xv. 51, 52; 1 Thess. iv. 13-18; Heb. x. 25, 37; 1 Peter iv. 7; 2 Peter iii. 8-14; Rev. i. 3, 7, iii. 11, &c.). As a natural consequence of interpreting such passages literally, Millenarianism (Gr. *Chiliasm*, from *chilioi*, 1000) became the general belief of the time, except among the Gnostics. At the same time there are hints in the New Testament itself of an uneasiness respecting the tardy fulfilment of the Messianic hope, and a suspicion that the time appointed for the advent had passed, in the numerous exhortations to patience in waiting for it (cf. 1 Thess. i. 10; 2 Thess. iii. 5; James v. 7, 8). As time passed on these suspicions seem to have ripened into open unbelief (cf. 2 Peter iii. 4; Jude 17-21). To meet this difficulty the time of Christ's advent was put back from time to time, e.g., in the Epistle of Barnabas it is put at the Jewish period—the end of 6000 years of the world's age. But the opposition to the belief now assumed a new form. The idea spread from the Alexandrian divines that the passages in the Bible which seemed to teach the doctrine of a M. were to be interpreted spiritually or allegorically. The first to put forth this idea were Caius at Rome and Origen at Alexandria. Origen's teaching was more effectually followed up by his pupil Dionysius, bishop of Alexandria (248-265), and Millenarianism being further brought into disrepute as part of the creed of the Montanists (q. v.), the doctrine ceased to be part of the orthodox faith of the Church.

The distinctive feature of Millenarianism has always been the twofold resurrection, so that a modern term for the doctrine is the *Pre-millennial* theory of the Advent of Christ. 1. At the coming of Christ, which is to be personal and glorious, the martyrs, or all who sleep in Jesus, shall be raised from the dead, in order to participate with the saints alive at the time, who are

to be 'changed' (1 Cor. xv. 51, 52; 1 Thess. iv. 13-17), in the kingdom he is to establish at Jerusalem. This is the First Resurrection of Rev. xx. 6. 2. The Jews are to be converted, restored to their own land, invested with special honours and prerogatives, and made the instruments of the conversion of the world. 3. This kingdom is to be one of great splendour, prosperity, and blessedness, and is to last a thousand years. 4. At the end of the M. the second or general resurrection of the dead and the end of the world are to take place. What has been the orthodox doctrine of the Church since the 3d c. is 'that the conversion of the world, the restoration of the Jews, and the destruction of Antichrist are to precede the second coming of Christ, which event will be attended by the general resurrection of the dead, the final judgment, the end of the world, and the consummation of the Church.' See Hodge's *Syst. Theol.* (Edinb. 1873), Gieseler's *Lehrbuch d. Kirchengesch.* (Eng. trans. 1855), Brown's *Christ's Second Coming* (1853), Sciss's *The Last Times and the Great Consummation* (Lond. 1866).

Mill'epede (Lat. 'having a thousand feet'), a name given to animals belonging to the class *Myriapoda*. They form the various genera of arthropodous representatives of the division *Chilognatha*, in which a great number of legs exist; each segment, except the anterior ones, being formed of two united segments, and thus the M. appears to have two pairs of limbs. The antennæ consist of 6 or 7 joints. Two pairs of mandibles are developed. The generative organs open anteriorly. The Common M. (*Julus terrestris*) is found among damp moss, and in like situations. It is sometimes named the 'Hairy Worm,' and coils itself into a spiral form when irritated. Other genera often named Millepedes are *Polydesmus* and *Glomeris*.

Miller, Hugh, son of a seaman, was born at Cromarty in Scotland, October 10, 1802; became an orphan in his fifth year, was educated at the grammar-school of his native place, and left it to work as a stone-mason. The publication of *Poems written in the Leisure Hours of a Journeyman Mason* (1829) secured for him the clerkship in a local bank, which gave him leisure to develop more freely his ardent passion for geological pursuits and reading in English literature. Contributions to the *Inverness Courier*, and *Scenes and Legends of the North of Scotland* (1835), were the first fruits of this leisure. Meanwhile M. was being deeply stirred by the great ecclesiastical controversy then beginning to rage over Scotland. His *Letter to Lord Brougham* on the 'Auchterarder Case' hurried him into the arena of public gladiators, and in 1840 he was summoned to Edinburgh to conduct the *Witness*, the organ of the Non-Intrusion party. In its columns appeared *The Old Red Sandstone*, a series of geological articles which set forth the results of original and valuable research in picturesque and pellucid English. M. was the first of the physicists who, without diminution of their scientific merits, have sought to rival litterateurs in the graces of language. Lyell, Murchison, and Buckland quickly recognised the advent of a fresh and powerful mind. During the struggle ending in the Disruption of the Church of Scotland in 1843, M. gave up all the strength and energy of his rugged soul to the service of the section that afterwards formed the Free Church, and the nobler exercise of his genius was for a while suspended. Yet his *First Impressions of England and its People* (1847), and his *Footprints of the Creator* (1849), called forth by the *Vestiges of Creation*, proved that the vigour and beauty of his diction had suffered no abatement, while his patient pursuit of geological science was shown in the *Testimony of the Rocks* (1857), *Cruise of the Betsy* (1858), and the *Sketch Book of Popular Geology*, edited by Mrs. Miller (1869). But overwhelmed by the quantity of work which pressed upon him through the calls of journalism, literature, and science, on the 23d December 1856, in a fit of insanity, he shot himself at Portobello. M. was a man of great power, of noble, serious, and intense character, with a truly Scottish perseverance and a vast capacity for work. Considering his meagre outfit of culture, and the narrow range of his early associations, his achievements and his accomplishments are incontestable evidence of the native richness of his mind. He has left an indelible mark in the history of geology, and will long be affectionately remembered by all classes of his countrymen. See *My Schools and Schoolmasters* for a record of his earlier career; also P. Bayne's *Life of Hugh Miller* (2 vols. Lond. 1871).

Miller's Thumb. See **BULLHEAD**.

Mill'et is the name of numerous grasses of varied habit, of wide geographical range, and of great value in an economic point of view, forming indeed in many countries the staple food crops of the people. The genera *Panicum*, *Setaria*, and *Sorghum* furnish the chief supply. Of the first, *P. miliaceum* is largely cultivated in India, producing ovate, smooth, shining, various-coloured seeds, about an eighth of an inch in length. Besides furnishing a palatable and nutritious table food, it is one of the best of all grasses grown for poultry use. In the common kind the grain is yellow; in other varieties white, gray, or black. *P. frumentaceum* and *P. miliare* are also frequently cultivated in India, yielding a seed largely used for food both by men and cattle. *P. spectabile* is grown in Brazil. Of *Setaria*, the seed of *S. Italica* is largely used in Italy in the preparation of a kind of flour which is made into bread, or, when finely pulverised, into pastry, and a light food for invalids. In India it is cultivated on light dry soils, yielding two crops in the course of the season. Under the name of German M. a variety of the above (*Germanica*) is grown in Moravia, S. Hungary, and Lombardy. It is known as 'Molar' by the Germans, and the seeds are used for making bread, as well as for boiling in soup and in milk, and they are also used for feeding domestic animals. In the genus *Sorghum*, the most important is *S. vulgare*, some of its varieties growing to a height of 7 feet. The seeds are large, nearly oval, and very variable in colour in the different varieties, some being white, others yellow, and others again reddish or black. In one or other of these forms the species is largely cultivated in Italy, Spain, and other parts of Southern Europe; in Egypt, Asia Minor, Arabia, and India (where it is called 'Dhurra'); and in W. and Central Africa. *S. saccharatum* is generally known under the name of sugar M. In America a good deal of attention has been paid to this plant, and to the manufacture of sugar from its stalks. Under the name of 'Gero,' the round grains of *Pennisetia spicata* are in daily household use by the natives on the rivers Niger and Gambia. This M. is eaten raw, or cooked in a variety of ways, and is further used for making several kinds of beverages.

Mill'rind, **Mill'rine**, or **Fer de Mouline**, in Heraldry, is the iron fixed to the centre of a millstone. It is a species of *cross moline*, and has its extremities in the form of a W.

Mil'man, Henry Hart, D.D., son of Sir Francis M., physician to George III., was born at London, February 10, 1791. Educated at Eton, he proceeded to Brasenose College, Oxford, of which, after taking the degrees of B.A. and M.A., he became Fellow. In 1812 he obtained the Newdigate poetry prize; and three years after he produced *Fazio*, a tragedy, put on the stage at Covent Garden. In 1817 he was appointed vicar of St. Mary's, Reading. In 1818 he published *Samor, Lord of the Bright City*, in 1820 *The Fall of Jerusalem* (perhaps his best poem); in 1821 he was elected Professor of Poetry at Oxford, and published *The Martyr of Antioch, Felschazar, Anne Poleyn*, in 1827 a series of Bampton Lectures, in 1829 *History of the Jews* (3 vols. new ed. 1863), in 1840 *History of Christianity, from the Birth of Christ to the Abolition of Paganism in the Roman Empire* (3 vols.), together with a collected edition of his *Poetical Works*. In 1849 he was made dean of St. Paul's, and in 1854 appeared the *History of Latin Christianity, including that of the Popes to the Pontificate of Nicholas V.* (3 vols.). The last of these is M.'s masterpiece, and has given him a distinguished place among historians. It is written with ample knowledge, philosophic acumen, and spiritual insight. The poet and the priest are finely blended in the work. To the first we owe, e.g., the picture of England in the days of Piers the Plowman; to the second, the picture of St. Francis of Assisi. M. lacks the majestic genius and the rich resources of Gibbon (whom he has edited), but he has the nobler merits of Christian faith and human sympathy. He died 24th September 1868. His *History of St. Paul's*, and *Savonarola, Erasmus, and other Essays*, were published posthumously.

Milne-Edwards, Henri, a distinguished French naturalist, the son of an Englishman, was born at Bruges in 1800, and studied medicine in Belgium and Paris, taking the degree of M.D. in 1823. He published his *Manuel de Matière Médicale* in 1825, *Manuel d'Anatomie Chirurgicale* in 1826, *Recherches pour servir à l'Histoire Naturelle* (1832-34), and his great work, *Histoire Naturelle des Crustacés* (3 vols. 1834-41). He was elected Member of the Academy of Sciences in 1838, Professor of En-

tomology at the Jardin des Plantes in 1841, Professor of Zoology in the Faculty of Sciences in 1844, and subsequently President of the Faculty. His *Elements de Zoologie* appeared in 1834-37 (2d edition in 4 vol., with 600 engravings, 1840-43). In 1841 he issued a *Cours Élémentaire de Zoologie*, and a work on the compound Ascidian Mollusca, beautifully illustrated, and full of fresh and interesting discovery. His *Leçons sur la Physiologie et l'Anatomie comparée de l'Homme et des Animaux*, appeared in 1857. He received the honorary degree of M.D. from the University of Leyden in 1875.

Mil'ner, Joseph, born near Leeds, January 2, 1744, graduated at Cambridge in 1766, became soon after headmaster of Hull Grammar School, where he died 15th November 1797. In 1794 he published three volumes of a *History of the Church of Christ*, once popular, but very narrow-minded, and now almost forgotten. A fourth volume, added by his brother **Isaac M.** (born January 1, 1751, died April 1, 1820), Dean of Carlisle, brought the work down to the Reformation.

Milnes, Monckton. See HOUGHTON.

Milon, of Croton in Magna Græcia, a famous athlete of the 6th c. B.C., who was six times victor in wrestling at the Olympic and the Pythian games. Many stories were told of his extraordinary powers, as that he carried a four-year-old heifer on his shoulders through the stadium at Olympia, and afterwards ate it all in one day. He had half succeeded in rending the trunk of a great tree with his hands, when the wood closed on them, and held him fast till he was devoured by wolves.

Milosch' Obren'ovitch, Prince of Servia, was born in 1784 in the village of Dobrinja, in the Servian circle of Uschica. He was the son of a day-labourer, and along with his half-brother Milan joined Czerny Georg (see CZERNY) in his struggle with the Turks. Milan died in 1810, but M. soon came to the front as one of the bravest and most successful warriors of the Servians. In 1813 his splendid defence of the village of Rawanj threw into the shade even the achievements of Czerny Georg himself. On the great uprising of the Servians, on the Palm Sunday of 1815, he placed himself at their head, and after long and chequered fighting finally secured the freedom of his country. At the peace of 1816 he was recognised by the Sultan as Woiwode of Servia, and in 1817 he was chosen by the nobles and clergy hereditary Prince of Servia. He ruled not without skill but very despotically till 1839, when he was compelled to resign his authority and was banished. He was succeeded by his son, **Milan M. O.**, who died twelve days after he had assumed the government, and in turn was succeeded by M.'s second son **Michael** (born 16th September 1823), who in 1842 was forced to make way for Karađorđevitch, son of Czerny Georg. On the fall of the latter in 1858, the Servian Skuptchina recalled the grey-haired exile M., who died 26th September 1860.

Milreis' (a thousand *reis*), the standard coin of Portugal. Its average exchange value is 4s. 4½d., or about 4½ M. to £1 sterling. The Brazilian M. is valued at 2s. 3d.

Miltiades, a 'tyrant' of the Chersonesus, of Athenian descent, who having incurred the enmity of Darius by his conquest of Lemnos and Imbros (494 B.C.), repaired to Athens, and on the second Persian invasion of Greece (490) was chosen one of the ten generals of the Athenian and Platæan forces. To his foresight and valour the great victory of Marathon (q. v.) was wholly due—hence Byron calls him 'freedom's best and bravest friend'; yet having failed in an attack with seventy ships on the island of Paros, he was impeached by Xanthippus on his return to Athens, and thrown into prison, where he shortly after died.

Mil'ton, John, was born in Bread Street, London, 9th December 1608. His father was a scrivener, of Puritan leanings yet liberal tastes, and especially skilled in music. M.'s first teacher was Thomas Young, a Scotchman and a Puritan, from whose care he passed to St. Paul's School. Here his habits of study were formed. Aubrey states that he commonly sat till past midnight, and mentions a turn for composing verses even then noticeable. Of these verses two specimens remain in the English Paraphrases of Psalms cxiv. and cxxvi., rendered when he was fifteen. He entered as a pensioner at Christ's College, Cambridge, 12th February 1625, being committed to the charge of a Mr. Chappell, afterwards Bishop of Cork and Ross.

With this tutor he had differences which led him to retire from the university during part of his third year of residence; but he returned, and under the guidance of the Rev. Nathaniel Tovey completed his course, taking the degree of B.A. in January 1629, and that of M.A. in July 1632. He left the University with high reputation as a scholar, but nicknamed 'the Lady,' as he himself confesses with a candour not unmingled with pride, because of his delicate appearance and reserved manners. The following of his extant writings are what, according to Masson, by this time lay in MS.: In Latin—the first four of the *Familiar Epistles*, and seven college themes afterwards published with these as *Prolusiones quedam Oratorie*; the first seven pieces in the *Elegiarum Liber*; and the first six in *Sylvarum Liber*. In English—*On the Death of a Fair Infant Dying of a Cough*, 1626; part of a *Vacation Exercise at College*, 1628; the *Hymn on the Nativity*, 1629; *On the Passion*, 1630; *On Time*, 1630; *On the Circumcision*, 1630; *At a Solemn Musick*, 1630; *Song on May Morning*, 1630; *On Shakspeare*, 1630; *On the University-Carrier*; *Another on the same*; *An Epitaph on the Marchioness of Winchester*, 1631; *Sonnet* on his twenty-third birthday, 1631. The deep-toned verses on Shakspeare, written in his twenty-fourth year, were prefixed anonymously to the second folio of Shakspeare—how proud a homage silently rendered by genius to kindred genius!

For five years after leaving Cambridge M. resided with his father at Horton, giving up thoughts once entertained of the Church, and applying himself to the study of modern literature, besides mathematics and music. Characteristically he chose the most solemn instruments to play upon, the organ and the bass viol. With the spirit of classical antiquity his mind was richly imbued; its air was native to him; and his meditations moved to the stately step of its sages. A long list of projected dramas and other poems was written at this time, and still exists. What he did accomplish during these five years placed him high in the first rank of the world's poets. We have: three of the *Familiar Epistles*; the *Sonnet to the Nightingale*; *L'Allegro*, and *Il Penseroso*,—the one musical with the sound of rural joys, breathing the breath of summer, every word a drop of honey,—the other gentle and serious, with the nightingale's song to the wandering moon, the sullen clang of the curfew, and the winds rocking the trees; *Arcades*, part of an entertainment before the Countess of Derby at Harefield, 1633; *Comus*, presented at Ludlow Castle before Lord Bridgewater in 1634,—the most exquisite dramatic poem the imagination of man ever conceived; *Lycidas*, 1637, an elegy on the death of a college companion, Edward King, containing passages of the tenderest pathos, here and there disclosing already the author's hostility to the spirit of the times.

On the death of his mother in 1637 M. went abroad, travelled for fifteen months in France and Italy, and returned by Geneva,—somewhat hurriedly because of the civil disturbances in England. He did not again take up residence with his father, but opened a school in London, first in St. Bride's Churchyard, afterwards in Aldersgate Street. The ensuing period of his life connects itself intimately with his country's struggles for freedom. He began soldiering with a sturdy attack on prelacy, entitled *Of Reformation, touching Church Discipline in England*, backed by other two pamphlets, *Of Prelatical Episcopacy*, and *The Reason of Church Government urged against Prelacy*. A knot of M.'s associates, under the name of Smectymnuus (formed by their initials), took up the cudgels; they were attacked by Bishop Hall; M. thereupon wound up the controversy for the time with *Animadversions upon the Remonstrant's Defence*, and finally with an *Apology against a Pamphlet called 'A Modest Confutation of the Animadversions upon the Remonstrant against Smectymnuus.'* In 1643 he married Mary, daughter of a Royalist called Powell in Oxfordshire; but the ignorant country girl quickly tired of a student for her husband, and ran home to her father's house, whence no entreaties could for a time recall her. At once making his private misfortune a matter of general principle, perhaps somewhat satisfied to have opportunity for broaching his matured though startling views, he printed four tracts on divorce: *The Doctrine and Discipline of Divorce restored to the good of both sexes from the bondage of Canon Law* (1644); *The Judgment of Martin Bucer touching Divorce* (translated extracts—1644); *Tetrachordon, or Expositions upon the four chief places in Scripture which treat of Marriage or Nullities in Marriage* (1645); and *Colasterion, a Reply to a Nameless*

Answer against the Doctrine and Discipline of Divorce (1645). In these he advocated moral incompatibility as ground for divorce. However, towards the close of 1645 his wife made peace with him. In 1644 he likewise wrote *On Education*, and his trumpet-toned *Areopagitica*, or *Speech for the Liberty of Unlicensed Printing*. In 1649 he defended the regicide of Charles I. in *The Tenure of Kings and Magistrates*, one of the ablest arguments ever penned in favour of the *jus populi*; upon the appearance of which and another tract—*Observations on Articles of Peace between the Earl of Ormond and the Irish Rebels*—he was appointed foreign secretary to the Council. He then removed to an official residence in Scotland Yard. There exist forty of his official Latin letters of this period. *Ikon Basilike* M., bitterly answered with *Ikonoklastes* (1649); and he silenced the *Defensio Regia pro Carolo Primo ad Carolum Secundum* of Salmasius with the crushing *Pro Populo Anglicano Defensio* (1651). In 1653 he became totally blind with gutta serena; and about the same time his wife died. Still he continued his duties as secretary under Cromwell, his dictated letters of this period numbering about eighty. In answer to strictures on his former Defence he produced *Defensio Secunda pro Populo Anglicano* (1654), followed by *Authoris pro se Defensio contra Alexandrum Morum, Ecclesiasten* (1655), and *Authoris ad Alexandri Mori Supplementum Responsio* (1655). The strictures were supposed to come from Alexander More, but Pierre Dumoulin really penned them. M.'s replies cannot be cleared from the charge of scurrility, but their effect was prodigious; they were translated into many languages, and became the talk of Europe. M. was married again in 1656 to Catherine, daughter of Captain Woodcock of Hackney; but in less than a year she died in childbirth. His writings of this period close with letters written for Richard Cromwell and the Parliament, and a few more tracts,—*A Treatise of Civil Power in Ecclesiastical Causes, Considerations touching the likeliest means to remove Hinderings out of the Church* (distinctly enunciating the Voluntary principle), *A Letter to a Friend concerning the Ruptures of the Commonwealth, The Ready and Easy Way to establish a Free Commonwealth, The Present Means and Brief Declaration of a Free Commonwealth*, and *Brief Notes upon a Late Sermon titled 'The Fear of God and the King.'* Thus for twenty years M. had produced nothing but polemics; seldom has a pen as mighty been so long devoted to strife; seldom have its triumphs at once been so immediate and so permanent. Stern and even fierce in his zeal for freedom, M., less a poet, might have proved a Cromwell.

In May 1660 Charles took the throne. M. remained in concealment till the passing of the Oblivion Act; and the cat's-paw parliament publicly burned his *Defence* and *Ikonoklastes*—the only honour these works had not yet attained. After his release he resided in Artillery Walk, and the unnatural conduct of his daughter induced him to marry Elizabeth, daughter of Mr. Minshall of Cheshire (February 1664). About the same time he published, or left in print, a school primer entitled *Accidence Commens Grammar, The History of Britain* (much of it written long before), *Artis Logice Plenior Institutio, Of True Religion, Epistolarum Familiarum Liber Unus, A Brief History of Moscovia and of other less-known Countries lying Eastward of Russia, Literæ Senatus Anglicani, Johannis Miltonis Angli de Doctrina Christiana ex Sacris dumtaxat Libris petita Disquisitionum Libri Duo*. To these we have to add *Paradise Lost* (1667), *Paradise Regained* (1671), and *Samson Agonistes* (1671). *Paradise Lost* was sold on the 27th of April 1667, to Simmons the bookseller for £5, and a contingent payment of two other equal sums on the sale of 2600 copies—£15 in all, no doubt an extraordinary price for an epic then. At the end of two years 1300 copies had been sold. It cannot therefore be supposed that the intelligence of the age failed to appreciate what will stand for ever as its monument, 'the noblest work,' says Voltaire, surely no partial judge, 'which human imagination has ever attempted.' Of *Paradise Regained* (the plan of which was suggested to M. by his secretary, Ellwood the quaker), and *Samson Agonistes* it may truly be affirmed that, were there no *Paradise Lost*, they would stand unrivalled in modern literature for wealth of fancy and depth of inspiration.

Old, blind, gouty, M. was now 'much more admired abroad than at home.' His habitual gravity and austerity had become bitterness; he held himself aloof from the profligate rabble around him: even by the learned was 'visited much more

than he did desire.' It is not, perhaps, singular that he attended no church, but it is certainly strange that so devout a spirit observed no private worship in his house. The apology of Johnson that M.'s life was a perpetual act of worship is at once magnanimous and true. M. died November 8, 1674, and was buried in St. Giles' Church, Cripplegate. To make the list of his works complete, it should be mentioned that he edited two MSS. of Raleigh—*The Cabinet Council* (1658), and *Aphorisms of State* (1661). His treatise *De Doctrina Christiana* was discovered in the State Paper Office in 1823, and edited by Bishop Sumner two years later. A *Commonplace Book* and a *Latin Essay and Latin Verses, presumed* (on almost conclusive proofs) to be by M. were edited for the Camden Society from MSS. in the possession of Sir F. U. Graham, Bart., by Alfred J. Horwood (1876). There have been more than 150 editions of M. published. Concordances to his works have been prepared by Pendergrast (Madras, 1857-59) and Cleveland (Lond. 1867). See Masson's *Life of M.* (Macmillan, vols. i. ii. iii. 1858, -71, -73, vols. iv. and v. in the press, 1877), his accurate edition of M.'s Poetical Works (1874), and the highly interesting and thoroughly German work—*M. und seine Zeit*, by Stern (Leipzig, 1877, vols. i. and ii.—to be completed). *Paradise Lost* is published in facsimile of the original edition by Elliot Stock (1877).

Milwaukee, the chief commercial city of Wisconsin, U.S., and a port of entry on the W. shore of Lake Michigan, 85 miles N. of Chicago by rail. It lies at the mouth of the river M., which is navigable 3 miles up for the largest lake vessels, and flows into M. Bay, a beautiful and sheltered inlet. M. is one of the largest primary wheat markets in the world, and the centre of 12 railways. In 1875, 310 vessels of 64,933 tons were enrolled at this port, and the elevators have a capacity of 3,800,000 bushels. In 1874 the direct exports to foreign countries of flour, grain, and provisions, amounted to \$2,165,163. The total quantity of wheat despatched was 22,255,380 bushels; of corn, 556,563; of oats, 726,035; of barley, 464,837; of rye, 79,870; of flour, 2,217,579 barrels; of wool 3,105,125 lbs.; of tobacco, 6,100,410 lbs.; of butter, 4,102,836; of cheese, 2,631,175; of hops, 10,780 bales; and of iron, 6986 tons. M. has 18 iron works, employing 2280 men, 10 large flour mills, 15 tanneries, extensive breweries, &c. Another great industry is pork-packing, the live and dressed hogs packed in 1871-75 numbering 248,197. The city, which was a mere village of the Ottawa tribe when visited by the first white settler in 1825, is now one of the most prosperous and elegant in the N.W. It has 28 newspapers, 10 of which are dailies. Pop. in 1840, 1750; in 1850, 20,000; in 1860, 45,286; in 1870, 71,499, and in 1875 (State census), 100,775, and in 1880, 115,578.

Mime (Gr. *mimo.*), a form of drama common to the Greeks and Romans, consisting of comic representations of life, often in extempore dialogue. The Greek M. appears first in Magna Græcia and Sicily, where it received its highest development from Sophron of Syracuse about 420 B.C. The Roman *Mimus* was of native growth, and, though consisting chiefly of mimic acting and low buffoonery, was more in favour than the regular drama. In the later period of the republic Mimes were introduced into the theatres, where they delighted Sulla and Julius Cæsar. Decius Laberius and Publius Syrus were then their most popular writers.

Mimicry, the name applied to that condition whereby certain animals or plants exhibit a marvellous resemblance in form or colour to other animals or plants, or to inorganic substances. As is well known, many animals (e.g., flounders, partridges, woodcocks) closely approximate in colour to their surroundings. But we find more typical examples of M. in such cases as the Leaf Insects (q. v.), or stick insects (*Phasmida*), where the wings and bodies respectively exhibit the closest M. of leaves and dried twigs. Certain inodorous butterflies of S. America so closely resemble their strong-smelling neighbours of a widely different kind, that the most careful examination is required for the detection and separation of the two forms. Among plants many curious examples of M. occur. The *Euphorbias* of Africa and the Cactaceæ of S. America—two groups widely separated from each other—so closely resemble each other, type by type, that the practised botanist alone can detect the difference between them.

Mimosa, a sub-order of the natural order *Leguminosæ*, numbering about 1000 species, chiefly belonging to the genera

Mimosa pudica.

Mimosa and *Acacia* (q. v.). The true *M.* are almost all tropical. The greater number are American, a few extending southwards beyond the tropics; some species are natives of Africa and E. India, but they do not appear in Australia, where the *Acacia* is so abundant. Only a small number are in cultivation, and these principally for the curious sensitive property of their leaves. The pods of another genus called *Prosepis* supply a large quantity of tannin, and the fruit having been found highly serviceable in America for cattle feeding, has been officially recommended (1877) for cultivation in Australia and S. Africa for like purposes. See MEZ-QUITTE and SENSITIVE PLANT.

Mimulus, a genus of herbaceous plants belonging to *Scrophulariaceæ*, numbering about 30 species, mostly American, with a few Australian and New Zealand. *M. luteus*—the monkey flower—a native of N. America, has now become naturalised in several parts of Britain. Many varieties of it have been raised, which have become garden favourites. The musk, so commonly grown as a window plant, is *M. moschatus*, a native of N.W. America. In the genus *M.* the stigma is bilabiate and irritable, the two lips collapsing together when touched with a sharp point.

Min'a, Lat. form of Gr. *Mna* (Heb. *maneh*; cf. Lat. *moneta*, and Eng. *money*), a Greek weight of 100 drachmæ, or 15 oz. 83.75 grs. It also meant a sum of money equal to 100 drachmæ, or £4, 1s. 3d.

Mina or **Mino Bird** (*Gracula musica*), a species of Indian coriostiral *Insectores*, famous for its talking powers, and for its general vivacity and intelligence. It attains the size of a thrush, and is of a deep velvety black, with white wing-quills. Two bright yellow wattles spring from the back of the head. The bill is conical, and the upper mandible slightly curved.

Min'aret, or **Minar**, the tall, narrow turret, characteristic of Saracenic architecture. It is divided into stories by balconies, and contains a staircase inside. From the top the Mohammedan priests summon the faithful to prayer by the voice. Minarets are properly accompaniments of the mosque, one at each of the four corners of the main building; but in India are sometimes erected apart as pillars of victory—e.g., the Kutub Minar at Delhi.

Min'aret, or **Minar**, the tall, narrow turret, characteristic of Saracenic architecture. It is divided into stories by balconies, and contains a staircase inside. From the top the Mohammedan priests summon the faithful to prayer by the voice. Minarets are properly accompaniments of the mosque, one at each of the four corners of the main building; but in India are sometimes erected apart as pillars of victory—e.g., the Kutub Minar at Delhi.

Minch, a channel off the W. coast of Scotland, some 30 miles in average breadth, separating the island of Lewis from the county of Ross and Cromarty. The little *M.* is the channel, 15 miles broad, between the islands of N. Uist and Skye.

Min'cio, the *Mincius* of the Romans, a river of N. Italy, issues from the S. end of Lake Garda, flows S. and then S.E., till after a course of 38 miles it falls into the Po, 8 miles below Mantua, to which city it is navigable for barges.

Mind. The most popular and at the same time the most accurate and truly scientific definition of *M.* is—'not-matter.' This is altogether apart from any metaphysical questions as to whether either *M.* or matter is a substance existing by itself; or whether *M.* is something different from mental states; or whether *M.* is ultimately dependent on material conditions from which it differs in kind; or whether the destruction of *M.* is conceivable, and, if inconceivable, whether it may be safely denied. On any of these assumptions, there is a great class of conscious states which all agree in calling *M.* Such are pleasures, pains, volitions, thoughts; the whole internal subjective non-extended

world as distinct from the extended objective world of matter presented in perception. In one sense, of course, matter is also *M.*, because assuredly, whatever may be our theory as to the connection between the two, matter is known only as a mental modification. But the tendency of modern scientific thought is to regard subject and object as rather two sides or aspects of one inscrutable reality; and, of these, *M.* is the subjective or spiritual side; it may be only the psychological function of nervous organisation, or it may be a parallel and independent stream in pre-established harmony with the other. *M.* has been often divided into numerous faculties and powers, which represented the more or less hasty conclusions of thinkers with regard to what seemed ultimate and undecomposable mental facts. Such divisions (e.g., that of Reid, into intellectual and active, sinking out of view, at least in name, the element of feeling) tend to conceal the fact that not only are complex operations of, e.g., the intellect proper, the product of few and simple laws of intellectual changes, but they are also in their growth inextricably intertwined with the constant play of the other fundamental powers of the *M.*, viz., feeling and will. The human *M.* must always be considered (at least in its higher processes) as one, and not many separate powers, though for the purposes of analysis it is necessary to distinguish and trace the separate action of the powers.

Mindana'o, the most southerly, and after Luzon the largest of the Philippine Islands. Area, 30,000 sq. miles. It is hilly and woody, of volcanic origin, and produces rice, cotton, spices, coal, gold, &c. Only parts stretching along the E. and N.E. coasts are occupied by the Spaniards, who number 74,000. The rest is in the possession of independent and savage tribes, greatly addicted to piracy.

Min'den, a strongly-fortified town in Prussia, province of Westphalia, on the left bank of the Weser, 40½ miles W. by S. of Hanover by rail. It has a stone bridge (1518) over the Weser 640 feet long, and a railway bridge of 6066 feet, 7 churches, among which the Domkirche (1072–1290) is the most conspicuous. There is considerable river traffic, and tobacco, leather, soap, and beet-sugar, are manufactured. At Todtenhausen, 3 miles N., Duke Ferdinand of Brunswick defeated the French under Contades, 1st August 1750. Pop. (1875) 17,088.

Mineral'ogy (Fr. *minéralogie*, from *minéral*, 'what is got by mining,' from *miner*, 'to mine,' and that from Lat. *minuere*, 'to drive or toss about'), is that branch of geology which treats of the formation, composition, and classification of minerals. A mineral is generally defined as a substance not possessing organic vitality, but having a definite chemical composition, and usually a geometric form. Rocks are a collection of minerals, and hence upon a good knowledge of *M.* must a really true knowledge of geology depend. According to the above definition, minerals include not merely the numerous varieties of quartz, felspar, and the metallic ores, but also the metals and elements which are found native, and even water, naphtha, petroleum, &c., for these chemically compound liquids differ from the solids only in having different temperatures at which their physical changes of state occur. If our globe were a few degrees colder, we would have water in a solid condition, very much resembling in appearance ordinary rock salt. Minerals are distinguished from each other by (1) their physical properties, and (2) their chemical properties. The most important in the physical properties is the form in which a given mineral crystallises (see CRYSTALLOGRAPHY). Minerals are of course frequently found not crystallised; but even in their amorphous state they can often be readily distinguished by other physical tests—such, for instance, as their fusibility, and their behaviour under the blow-pipe. Their position in the scale of hardness (see HARDNESS) is another important test. Little aid in determining a mineral can, as a rule, be got from the colour, which depends much upon the presence of foreign substances. This should always be noted, however, as well as the lustre, streak, form of fracture, &c.; for they are very useful as auxiliaries to other and better tests. Chemistry supplies several valuable methods by which minerals may be distinguished from each other. The acid test, for instance, can at once settle the question as to whether a mineral is a carbonate or not, since the carbonates as a rule effervesce under the action of a strong acid. Blow-pipe analysis has now assumed a first

position in the determination of minerals, and the microscope has become an absolute necessity to the mineralogist. See Dana's *System of M.* (1837, new ed. 1868), and *Manual of M.* (1857, new ed. 1873).

Mineral Tallow or Hatchettine (in honour of the eminent chemist Hatchett), a rare native hydrocarbon (approximately carbon 85.5, hydrogen 14.5), resembling beeswax or spermaceti. It occurs in Wales, near Merthyr-Tydvil, near Loch Fyne in Scotland, and also in Moravia.

Mineral Waters, a term usually applied to all spring waters which contain an excess of mineral ingredients above what is usually found in ordinary drinking water. They have been used from the earliest times as remedial agents, both for internal use and for bathing, thermal waters being used in all countries, and even by savage races for the latter purpose. The Greek and Roman physicians had great faith in their curative virtues, and the temples erected to Æsculapius were usually in close proximity to mineral springs. To the Romans we are indebted for the discovery of the mineral thermic springs in Italy, and some of the most important in other parts of Europe. M. W. have been variously classified as to their chemical composition; but the classification adopted by Dr. Althaus is perhaps the most convenient:—(1) Alkaline Waters, (2) Bitter Waters, (3) Muriated Waters, (4) Earthy Waters, (5) Indifferent Thermal Waters, (6) Chalybeates, (7) Sulphurous Waters.

1. The Alkaline Waters are divisible into (a) *simple alkaline acidulous waters*, the chief ingredients being carbonic acid and bicarbonate of soda. The principal waters of this class are the thermal springs of Vichy and the cold springs of Fachingen, Geilnau, and Bilin, and they are used in cases of indigestion, biliary and renal calculi, gravel, gout, chronic bronchitis, and abdominal plethora. (b) *Muriated alkaline acidulous waters*, which contain a considerable quantity of chloride of sodium, such as the thermal springs of Ems and the cold springs of Selters, Luhatschowitz, and Salzbrunn. They are used in chronic catarrhal affections, and the Ems water has a reputation in chronic diseases of the uterus. (c) *Alkaline saline waters*, whose chief contents are sulphate and bicarbonate of soda, such as the warm springs of Karlsbad and the cold springs of Marienbad, useful in cases of abdominal plethora depending upon habitual constipation from sedentary occupations, and congestion of the liver.

2. The Bitter Waters contain the sulphates of magnesia and soda, and the most celebrated are those of Pullna, Salschütz, Sedlitz, Friedrichshall, and Kissingen. They are useful as purgatives and diuretics when it is advisable to excite the action both of the bowels and kidneys. In England the bitter waters of Cherry Rock, in Gloucestershire, and of the Purton Spa, in Wiltshire, are used for similar purposes.

3. The Muriated Waters are divisible into: (a) *simple muriated waters*, containing a small quantity of chloride of sodium or common salt, such as the hot springs of Wiesbaden and Baden-Baden, the tepid springs of Soden in Nassau; of Mondorf at Luxembourg; and of Kanstatt near Stuttgart; and the cold springs of Kissingen, Homburg, and Cheltenham, useful in gout, rheumatism, scrofula, and abdominal plethora. (b) *Muriated lithic waters*, containing chlorides of sodium and lithia, such as Baden-Baden, Karlsbad, Franzensbad, Kissingen, and Weillach, useful in gout and periodic headache. (c) *Brines*, containing a large amount of chloride of sodium, such as Rehme and Mannheim, useful for bathing. (a) *Iodo-bromated muriated waters*, containing chloride of sodium and the iodides and bromides of sodium and magnesium, useful in cases of scrofulous infiltrations of the glands, scrofulous ulcers, chronic inflammation of the uterus, ovaries, &c., and in cases of bronchocele or goitre. The waters of this class are very numerous, but Kreuznach is the most celebrated.

4. Earthy Waters contain the sulphate and carbonate of lime, the most important being those of Wildungen, Leuk, Bath, Lucca, and Pisa, useful in chronic skin diseases, scrofula, gout, rheumatism, chronic catarrh of the bladder, dysuria, prostatic disease, &c. The first of these (Wildungen) is largely exported, and is said to be an excellent diuretic, promoting the elimination of gravel and renal calculi.

5. Indifferent Thermal Waters, containing a small amount of saline constituents, such as Gastein, Töplitz, Willbad, Plombières, Warmbrunn, Clifton and Buxton, useful for stimulating the skin and exciting the nervous system.

6. Chalybeate Waters, divisible into (a) *simple acidulous chalybeates*, containing carbonic acid and bicarbonate of protoxide of iron; and (b) *saline acidulous chalybeates*, containing sulphate of soda and bicarbonate of protoxide of iron. The waters of this class are very numerous, and are useful in cases of debility, and anæmia, chlorosis, &c. Among others may be mentioned Alexandersbad, Auteuil, Bocklet, Kössen, Kronthol, Lipp-springe, Soden, &c.

7. Sulphurous Waters, which contain sulphuretted hydrogen, or metallic sulphides, or both, useful in chronic diseases of the skin, gout, and rheumatism. The sulphurous waters are employed externally and internally. The principal thermal springs are those of Aix-la-Chapelle, Borette, Baden, Bâges, Eaux-Chaudes, and Bagnères de Luchon; and the cold are Labassère, Nenndorf, Eilsen, &c. See *Spas of Europe* (Lond. 1862), by Dr. Althaus; *Dictionnaire Général des Eaux Minérales et d'Hydrologie Médicale*, by MM. Durand-Fardel, Le Bret, and Lefort.

Minerva (Etruscan *Menrfa*, from the same root as *mens*, 'mind'), a virgin deity, worshipped by the Etruscans and Sabines, but especially at Rome, where she had ancient temples on the Capitoline, Aventine, and Cælian Hills. She was partly the goddess of courage and success in war, partly the impersonation of all intelligence and invention, and the tutelary deity of all handicrafts, arts, and sciences. Tarquin, son of Demaratus, joined her worship to that of Juno and Jupiter her father in a common temple, and she was said to have sometimes wielded the thunderbolts of Jove. The festival of M. lasted five days (from 19th to 23d March), and was called 'Quinquatrus.' Her image was preserved in the inmost recess of the temple of Vesta, and was believed to be one of the chief safeguards of Rome. Latterly M. was identified by the Romans with the Greek Athena. See Hartung, *Religion der Römer*.

Athênê (in the Vedas, *Ahana* is the 'Dawn'), or *Fallas*, *Athênê*, called by Homer a daughter of Zeus, and in later traditions said to have sprung in full armour from the head of Zeus, was one of the chief divinities of the Greeks, and the tutelary deity of Athens. She was regarded as the protectress of the state and of all arts and inventions that were of avail for its defence and prosperity. Athena invented the plough, the rake, the trumpet, the chariot, navigation, numbers, created the olive-tree, taught men to use fire, oxen, horses, and all instruments of tillage. Her powerful intellect and wise counsel gave her a place on the right hand of Zeus. Athena maintained law and order, and instituted the Areiopagus; was warlike, not for the sake of war, but when prudence demanded it, and was the especial protectress of heroes. She was worshipped throughout Hellas. Athens early derived her cult from the ancient towns on Lake Copais. Her sacrifices consisted of bulls, rams, and cows. Her great festivals at Athens were the *Panathenæa* (q. v.) and the *Arrephoria*. In the latter two maidens in their 7th year carried the splendidly embroidered *peplos* of Athena in solemn procession. The three great statues of Athena by Phidias were held perfect. The first, of gold and ivory, and of colossal size, stood on the Acropolis; the second, of bronze, was made out of the spoils of Marathon; the third was called the 'Iemnian' or 'Beautiful Athena.' In the numerous representations of Athena she wears a figured helmet, an ægis, a sleeveless tunic partly covered with the *peplos* or cloak, and bears a round Argolic shield on which is the head of the Gorgon Medusa.

Minervino, a town of S. Italy, province of Bari, on a height overlooking an affluent of the Ollanto, 24 miles S.W. of Barletta. It has a considerable trade, and on account of its extensive views is called the 'balcony' of Apulia. Pop (1874) 13,844.

Mines, Military, are subterranean passages used in modern warfare for depositing quantities of gunpowder for subsequent explosion. They were originally employed merely to furnish secret access to a fortified place, or to afford the means of undermining the walls. The besieged were not slow to follow the same device, and were often successful, not only in averting threatened danger to their walls, but also in damaging the battering-rams and war-engines of their foes. When the mines of hostile parties met, fierce subterranean encounters resulted. About two centuries after its discovery, gunpowder was first used in mining tactics by a Genoese engineer, who in 1487 unsuccessfully attempted to open a breach in the citadel of Sassano in Tuscany. Subsequent

attempts by Pedro Navarro, a Spanish captain, were more successful; and in the beginning of the 16th c. the excavation and firing of mines became general. The besieged were ultimately forced to run out *countermines*, from which a practised ear could readily tell the direction in which the enemy was working his mine, and could take measures to meet the threatened attack. The vertical portion of a mine is called a *shaft*, and the horizontal portion a *gallery*. The sides of a gallery must be lined—ordinarily with wooden frames or cases—to prevent the loose earth from falling in and filling up the passage. In driving a long gallery, means for ventilation must be carefully looked to; and the possibility of the powder becoming moist when deposited in the *chamber* must be guarded against. The powder may be fired by a safety fuse, a powder hose, or more preferably by an electric current. To prevent the explosion from spending its energy otherwise than is desired, the gallery leading from the chamber must be filled up from a certain distance with solid material. This operation is called *tamping*; and the most convenient materials for tamping are sand-bags, or bags containing loose earth or sand, which can be readily deposited or removed. The commotion caused by the explosion extends of course in all directions, and the distances at which the disturbance is felt are called the *radii of rupture*. The surface of the ground directly over the position of the exploded charge forms a more or less circular opening, called the *crater*; and the relation of the diameter of the centre to the vertical line from the chamber to the surface is a measure of the force of the explosion.

Minghetti, Cavaliere Marco, an Italian statesman, born at Bologna, September 8, 1818, educated in his native city, travelled in Italy, France, England, and Germany, and in 1846 founded a newspaper, *Il Felice*, advocating economic and political reform. In 1848 M. acted at Rome as Minister of Public Works, but in the same year entered the military service of the King of Sardinia, displaying great bravery in the unfortunate campaign which cost Charles Albert his crown. Under Cavour he served as Foreign Minister, in 1860 became Minister of the Interior; in 1863 President of the Council, and in 1868 ambassador in England. He was Prime Minister of the kingdom of Italy from 1873 to 1876. His chief works are *Della Economia Pubblica* (1859), and *Opuscoli Letterari* (1872).

Min'ho (Sp. *Miño*), a river that rises in the N.E. of Galicia, Spain, flows in a S.W. direction, forms part of the N. boundary of Portugal, and enters the Atlantic at Caminha after a course of 130 miles, 20 of which are navigable. M. is the ancient Minius.

Miniature Painting is a branch of fine art, embracing the production chiefly of portraits on a very small scale. The paintings were done in early times on vellum, but subsequently ivory was very extensively used. The term *miniature* is derived from the Latin *minium*, red lead, the connection being found in the fact that the art of M. P. developed from the practice of illuminating initial and other leading letters in ancient and mediæval MSS. with red lead and vermilion. The small figures introduced into such illuminations were by the Italians called *miniatura*, and hence when the practice of separately painting minute portraits arose, they were known by the same name. The development of the art of photography, and the perfection attained in the production of portraits by that means, have dealt a fatal blow to M. P. as a professional pursuit, and the art is now practised by very few. Many artists, e.g., Holbein, Millard, the two Olivers, Cooper, and Hoskins, attained great eminence as miniature painters. The term *miniature* is now applied to any painting, drawing, or other object executed on a scale very much reduced from its ordinary proportions.

Minié Rifle. See RIFLED ARMS.

Mini'm (Fr. *minime*, Lat. *minimus*, 'the least') is the name of a small note in music equal to two crotchets.

Min'im's (*Fratres Minimi*, 'the least of all friars'), a religious order founded (1435) by St. Francis of Paula (q. v.), under the title 'Eremites of St. Francis,' and confirmed (1474) by Sixtus IV., and (1492) by Alexander VI., who changed its name to M. It spread into France in 1482, into Germany under Maximilian I., and under Ferdinand the Catholic into Spain, and in these three countries the M. were respectively known as *Bon-hommes*, *Pauliner*, and *Fratres de Victoria* (the conquest of Malaga being

ascribed to their prayers). In Spain the first convent of nuns of the order was founded in 1495; in France, in 1621. The rule is based on that of the Franciscans, of whom the M. are regarded as a branch; but to the three vows of poverty, chastity, and obedience is added a fourth of perpetual fast (*vita quadragesimalis*). The superior is styled *Corrector*, and the habit consists of a tawny cassock, with hood, scapular, and leathern girdle.

Mining is the method by which the wealth of the mineral kingdom is reached and secured for human use. All excavations made by man within the bowels of the earth, whether carried on with the view of obtaining mineral treasures or not, are called M., and in siege operations of war, military M. occupies a prominent place. (See MINES, MILITARY.) The industrial operations of M. are most largely concerned in obtaining the ores of metals and coal; but saline deposits, sulphur ores, precious and ornamental stones, and various non-metallic minerals are also of great importance in the range of M. pursuits. Quarrying may be regarded as a subdivision of M. concerned with obtaining stone for building and other purposes, entirely by means of open excavation. As the rock-masses that form the earth are divided into stratified and unstratified deposits, so also the mineral wealth they inclose is found arranged either in regular beds or strata, and in lodes or veins, irregular masses, and nodules, &c. As these distinctions of stratified and unstratified deposits give rise to two quite distinct classes of M. operations, they will be here separately noticed. From stratified rocks are principally obtained the varieties of coal, bituminous and aluminous shale, and several of the most important iron ores. In veins, &c., are found the metallic minerals other than these iron ores, and the veins are chiefly disseminated in igneous and metamorphic, or so-called primitive rocks. Although in Great Britain especially, and generally also in other countries, the old reformation is richest in mineral wealth, neither carbonaceous nor metallic minerals are confined to any particular series of rocks, but are found in the deposits of all periods, from the palæozoic to the most recent.

Coal M.—From the fact that coal is disposed in regular beds or layers in stratified rocks, its working is more simple and easy than is the case with irregular veins of metalliferous ores. The presence, position, and thickness of coal-seams in any field are first ascertained by means of borings. The first consideration in the winning of the coal is whether the seam is at such a depth as renders it practicable to drain the pit to be formed by means of a 'day level' or gallery running from the lowest part of the pit into an open valley or watercourse at a height above the sea level. When this is impossible, as is now frequently the case, pumping machinery has to be provided sufficient to carry all the water which accumulates in the 'sump,' or lowest part of the pit to the height at which it can run freely away. Every coal pit must contain at least two shafts or openings to the surface of the earth, and these, when the seams are disposed in a nearly horizontal manner and at a considerable depth under the surface, are cut in a vertical direction through the superincumbent strata. But when the seams crop out to the surface, and dip downward in a basin-shaped field, the dip may be followed by one of the shafts, and the coal is sometimes pulled up the inclined plane of the strata. Through the main or engine shaft the coal is raised, and the colliers ascend and descend the pit, and in that shaft is also arranged the pumping machinery when such is required. The object of the second or bye shaft is to provide a means of egress to the miners should the main shaft be accidentally blocked, an occurrence which has sometimes caused enormous loss of life, and the bye shaft is also taken advantage of for ventilating the pit. The two shafts having been sunk to the seam to be worked, they are connected by a gallery or leading cut through the seam. The 'dip head level' is then run from each side of the bottom or engine shaft, it being a gallery cut in a perfectly horizontal or level direction along the seam, and forming the main line of communication from all parts of the workings to the engine shaft. The dip head level is the lowest part of the workings, the coal being worked from it upwards towards the outcrop or surface of the ground.

There are two principal methods by which the coal is worked, the one being known as the 'pillar and stall' or 'post and stall' plan, and the other is called the 'long wall' system. The pillar and stall system, which is that most commonly adopted, is shown

in plan in the accompanying figure (1), in which D is the main shaft, A B the dip head level, U the bye or ventilating shaft, and F a furnace for causing an inward draught of air through the shaft. The course of the current of air along the stalls or heads is indicated by arrows, and it will be observed that the direction of the current is controlled by doors placed across the passages.

Fig. 1.

The dark shaded portion indicates the pillars of coal left to support the roof, and a portion of one panel is completely worked out. As the coal is removed from this portion, called the goaf, all supports are withdrawn by the colliers who work backward in the direction of the shaft, and the roof falls in as the work proceeds. In excavating by the long wall system, the whole of the coal is worked away at once, access to the face of the wall or working place being preserved by artificial supports of debris, coal, or wood. In some cases roadways are driven through the solid coal seam in different directions to the extremities of the workings, from which the miners work back-

Fig. 2.

ward to the shaft, leaving nothing but goaf behind them. The long wall system is much more simple and economical than the

pillar and stall, as almost every fragment of coal can by it be worked out. It is on that account coming gradually into favour with mining engineers, and is now adopted in many localities where pillar and stall working formerly prevailed. The diagram (fig. 2) illustrates the varieties of long-wall working, showing at A advancing stalls or tooth work by which the face of the coal is taken; at B the coal is worked on its end, and at C D the workings are carried in a straight line without regard to the cleat or grain of the coal.

The work of the collier has generally to be performed under unfavourable circumstances, and in a very constrained position. With his pick he undercuts the seam to a depth of two or three feet, working either in the coal itself or in the under clay. The mass is then detached either by driving wedges into the upper part of the seam, or, in pits free from fire-damp, by blasting. Machinery for cutting coal has been successfully introduced in recent years, one of the most successful devices being the Gartscherie coal-cutting machine, worked by Messrs. W. Baird & Co. in their pits. The coal is loaded into small waggons or tubs, drawn to the main or engine shaft, and there raised to the pit head. In the prosecution of his arduous work the collier is subject to many serious risks, and the yearly average of fatal injuries in British coal mines alone exceeds one thousand. The most prolific causes of death are accidents from the fall of roof, from explosions of fire-damp, from breakages of rope and overwinding in the shaft, and from irruptions of water. The utmost precautions are taken for the prevention of such accidents by stringent regulations laid down by Act of Parliament and enforced by Government inspection, but nevertheless accidents involving great loss of life are still of frequent occurrence.

The deepest coal-pit in Great Britain is that at Dunkinfield in Cheshire, where coal is brought from a depth of 2504 feet below the surface, the engine shaft sinking vertically 2034 feet. The shaft of Sacree Madame l'it, near Charleroi in Belgium, is 2400 feet in depth. The expense of sinking some of the deeper shafts and of the engineering work of tubbing for keeping water out of the pits is often very great, from £80,000 to £100,000 having sometimes been expended before it became possible to commence the practical working out of the coal.

Metalliferous Mines.—The M. of clay band and black band iron ores which occur interstratified with coal in carboniferous deposits, is conducted under circumstances analogous to ordinary coal M. But ordinary metalliferous deposits which occur in veins or lodes are secured by a somewhat different series of processes. As the ore is in these disposed in all directions from horizontal to vertical, sometimes dwindling away into thin sheets, and sometimes expanding into huge masses, it cannot be attacked on any one plane. A main shaft is first sunk from the surface till it reaches the lode; from the shaft a series of horizontal galleries at regular distances from each other are run out, and between these galleries communication is established by means of minor shafts called winzes. In this manner the workings are carried out from the main shaft as far as it is deemed proper to go, and the direction and richness of the lodes being thus explored, the miner works back towards the centre, taking the rectangular blocks into which the mine has been divided in regular succession. These he may attack either from above or below, excavating in successive stages or steps, so that the work in progress has a stepped or stair-like aspect. In metalliferous mines a device called a 'man engine' (Ger. *fahrlkunst*), is employed for taking the miners to or from the workings. It consists either of one or two rods extending from the surface to the bottom of the shaft, on which at regular intervals are fixed a staging or platform on which a man can stand. The rods have a reciprocating motion, and in the case of a two rod machine, supposing one rod is raised say 12 feet while the other is depressed a corresponding distance, by alternately stepping from the platform of the one to the other the miner can either raise or lower himself the distance of 12 feet at each stroke of the apparatus. With single rod machines acting through a definite distance, at which intervals a fixed staging is attached to the shafting, the same raising or lowering can be accomplished. For details regarding this important pursuit there may be consulted Smyth's *Coal and Coal M.* (Lond. 1867); Cornwall, *its Mines and Miners* (Lond. 1855); Simomin's *Underground Life*, trans. by Bristow; and the article M. in *Ure's Dictionary* (7th ed. Lond. 1875).

Law Regarding Mines.—The general rule of law is that the owner of the surface of land is the owner of all below it, but gold and silver mines belong to the Crown, and when these metals are found mixed with others, then the Crown may take them at a valuation, in accordance with a statute. When land is let for agricultural purposes, the tenant is not entitled to open a mine, unless there be a stipulation to that effect. So, when land is taken to make a railway over it, the owner may retain and work a mine, but by common law he must not work it so as to endanger the railway. In Scotland, by the statute of 1424, gold mines are declared to belong to the Crown, without limitation; and silver mines also when the value of three half-pence of silver can be extracted from the pound of lead.

Minister Plenipotentiary. See MINISTRY.

Ministry in the political sense includes the chief officers of the Crown, who are selected from both Houses of Parliament, in order to carry on the executive government of the country. It was not until the Revolution of 1688 that the word began to take its present significance. 'Up to that time,' writes Mr. Freeman, 'the servants of the Crown had been servants of the Crown, each man in the personal discharge of his own office. The holder of each office owed faithful service to the Crown, and he was withal responsible to the law; but he stood in no official fellowship towards the holder of any other office. But William III. felt the necessity of having a committee harmoniously working together, the individual members of which should stand by each other, support the same measures, and work with unity of purpose. To these was gradually transferred the deliberations of all important questions relating to foreign and domestic policy before they were submitted to Parliament. The written law knows nothing of the Cabinet or Prime Minister; it knows them as members of one or the other House of Parliament, as privy councillors, as holders, each man in his own person, of certain offices; but as a collective body bound together by a common responsibility, the law never heard of them. But in the eye of the unwritten constitution the Prime Minister and the Cabinet of which he is the head, form the main features of our government.' It is, however, from the Privy Council that proclamations and warrants are signed and sent forth. A M. is formed by the sovereign calling upon a statesman, who has held office, to surround himself with colleagues whose ideas of policy accord with his own. It is dissolved by the House of Commons declining to pass a measure upon which the M. may have determined to stake their official existence. Neither can the sovereign keep a minister in office against the wishes of the House, nor remove him if he has their approval. It was not until the period of the Hanoverian dynasty that the king ceased to take a share in the deliberations of the Cabinet. A M. includes, besides the First Lord of the Treasury, who forms it, the Lord Chancellor, the Chancellor of the Exchequer, four Secretaries of State, the Secretary of War, the President of the Council, who are always members of the Cabinet, and the First Lord of the Admiralty, the Chief Secretary for Ireland, the Presidents of the Board of Trade and the Poor-Law Board, the Chancellor of the Duchy of Lancaster, who are not necessarily members but may be so. Other ministers are the Lord-Lieutenant of Ireland, the Attorneys-General and Solicitors-General for England and Ireland, the Lord Advocate and Solicitor-General for Scotland, the Vice-Presidents of the Board of Trade and the Education Committee, the Commander-in-Chief, the Lord Chamberlain, the Masters of the Horse and Buckhounds, the Steward and Comptroller of the Household. In diplomacy there are three orders of ministers, the highest being ambassadors, who completely represent their sovereign in the countries to which they are accredited. Ministers plenipotentiary, though they guard the interests of their countrymen, have a smaller representative power, and the third class, including the *chargés d'affaires*, though they discharge similar duties with the second, are not entitled to the same amount of ceremonial. See Macaulay's *History* (vol. iv.), and Freeman's *Growth of the English Constitution* (1872).

Minneapolis, a city of Minnesota, U.S., on both sides of the Mississippi, at the Falls of St. Anthony, 8 miles N.W. of St. Paul by rail, and 3 from the celebrated Falls of Minnehaha ('laughing water'). In 1877 it had 54 churches, 2 universities, 10 public schools, 21 flour-mills (producing 1,306,000 barrels yearly), 20 sawmills (turning out 200,000,000 feet of lumber),

besides shingle and lath mills, machine shops, foundries, woollen, oil, and paper mills, &c. The total yearly product of its manufacturing is about \$17,000,000. The two halves of the city were connected (1877) by a suspension bridge, 111 feet high and with a span of 675 feet, erected at a cost of \$200,000. Pop. (1877) 40,000.

Minn'esinger, or **Minn'esänger**, the name by which 160 German lyric poets of the 12th and 13th centuries are known. Soon after their first appearance in Upper Austria, the character of their poetry seems much modified by a French influence then diffused over the Rhine-lands. As they chiefly sang of love (*minne*), the whole literature took the name of *Minnesang*. Its later form originated in the district around the Maas, where chivalry was at its greatest height. The French influence was especially marked in the structure of the verse. The three chief forms were: (1) 'Lieder,' series of tripartite strophes, sung to the same melody, and sometimes accompanied with dancing, their subjects being either erotic, sacred, or eulogistic of lords and princes; (2) 'Leiche,' bipartite strophes of various melody, usually accompanied with dancing, except when the subjects were religious; (3) 'Sprüche,' in verses often of irregular form, whose usual subject was 'Gottes-und-Herrendienst,' and which were only meant for recitation. The 'Tageweise' or 'Taglied' celebrated the sad pining of two lovers at the dawn of day. In richness of form, and glow of passion, the 'Minnesang' stands very high. It demanded great artistic culture, and was chiefly cultivated by the sons of the lower nobility, who were taught music and poetry by the clergy. It was not, however, till its latest period that the art of the M. became an accomplishment; from a 'Meister' was expected originality of thought and form. The poems were sung by the poet himself to his harp; from him wandering minstrels learnt them; these were the first to write down and collect them; the older poets, e.g., Wolfram v. Eschenbach, could not even write. In the 13th c. the number of M. immensely increased; they flourished especially in Swabia and Thuringia, but were found at all German courts. The greatest names of the greatest period were Heinrich v. Veldeke, Reinmar v. Hagenau, Walther v. d. Vogelweide, Hartmann v. Aue, Gottfried v. Strassburg, Wolfram v. Eschenbach, and Ulrich v. Lichtenstein. Reinmar v. Zweter, a Rhinelander, from 1230 to 1260, treated subjects chiefly of a personal and public character, but his prosaic tendency shows the spirit of decline. Konrad v. Würzburg holds a higher place, especially for his narrative poems, and Reihart (1210-40) introduced a fresh humour into his pictures of popular life. About the close of the 13th c. the spirit of chivalry grew ruder, and gradually the *minne* poetry lost itself in the mechanical spiritlessness of the Meistersinger (q. v.). See Von der Hagen, *Minnesänger* (4 vols. 1838); Lachmann and Haupt, *Des Minnesangs Frühling* (1857); Taylor, *Lays of the M.* (Lond. 1825); A. E. Kroeger, *The M. of Germany* (Lond. 1873).

Minnesota, one of the N.W. states of the American Union, is bounded N. by the Dominion of Canada, S. by Iowa, E. by Wisconsin and Lake Superior, and W. by Dakota, from which it is partly separated by the Red River. Area, 85,531 sq. miles; pop. (1875) 609,777, including 12,370 tribal Indians. M. is 380 miles long from N. to S., and its greatest breadth is 337 miles. It is traversed in the N. by a range of flat drift-hills (the 'divide' between rivers flowing to Hudson's Bay and the Gulf of Mexico), 1680 feet above the sea, but nowhere more than 100 feet above the surrounding country, which to the extent of three-fourths is rolling prairie, interspersed with oak-openings and belts of hardwood timber, and dotted with numberless small lakes, covering $\frac{1}{4}$ th of the whole area. The chief rivers are the Mississippi, and its affluent the M. (from which the state is named), the Red River of the N. and the St. Louis. The first of these is navigable within the state for 540 miles. Towards Lake Superior there is a rich mineral tract, especially plentiful in iron and copper, while in the Red River Valley, and at Belle Plaine on M. River, the manufacture of salt has attained great success. Other products are gold and silver (in moderately paying quantities), lime, slate, tripoli, building-stone, peat, &c. The prevailing metamorphic and volcanic rocks are in great part covered by a fertile alluvium, which is admirably adapted in the N. to wheat-culture and grazing. About one-third of the entire surface is under dense forests of oak, beech, elm, maple, pine, spruce, &c. The vast encroachments of the lumber trade have been

compensated by the planting already of some 20,000,000 forest-trees on the prairies. The climate is remarkably healthy and bracing, the mean summer temperature being 70° 50', while that of winter is 16° 10'. M. is one of the great wheat-growing States, and has now an area of 2,622,324 acres in grain crops alone. In 1875 the yield of wheat was 31,475,000 bushels; of oats, 15,775,000; of corn, 9,500,000; of barley, 1,585,000; of rye, 70,000; and of buckwheat, 31,500. The growth of potatoes was 3,250,000 bushels, of flax, 1,227,547 lbs., and of tobacco, 28,324. In 1875, M. had 167,313 horses, 467,578 cattle, 5257 mules and asses, 162,807 sheep, and 141,810 hogs. Five million bushels of the wheat are made into flour by the mills of the State, and M. flour retains the first rank. Besides flour-milling the other great industry is lumbering, the lumber produced in 1874 being 421,000,000 feet, value \$5,500,000. In 1875 there were in M. 2227 miles of railway. St. Paul is the capital, and other towns are Minneapolis and Winona. The French missionaries found their way hither in 1680. The real work of settlement did not begin till 1805, and M. was only organised as a Territory in 1849. Its subsequent development was singularly rapid, and it was made a State in 1858.—**M. River** rises in Big Stone Lake, on the E. boundary of Dakota, flows first S.E., and then N.E. through the 'Big Woods' in the State to which it gives name, joining the Mississippi 5 miles above St. Paul, after a course of 470 miles, of which 300 miles are navigable during high water.

Minn'ow (*Leuciscus phoxinus*), a small species of Teleostean fishes belonging to the *Cyprinidae* or Carp family, and allied to the Dace (q. v.), Chub (q. v.), and other fishes. It inhabits streams and rivers, and is usually found in clear water. The M. may attain a length of 3 inches, but is usually much smaller. The upper surface is of a dirty grey or olive colour, the under parts being silvery white. The M. is a favourite bait for pike and perch.

Min'or, in Law. See AGE.

Minor (Music). See INTERVAL, MODE, SCALE.

Minor'ca, the second largest of the Balearic Isles, lies 25 miles N.E. of Majorca, in the Mediterranean. Area 335 sq. miles; pop. 39,005. Its coast is much indented, especially in the N., and the surface is hilly, rising in El Toro to a height of 4793 feet. Less fertile than Majorca, it produces oil, wine, hemp, zulla, wheat, barley, and fruits. The main industry is the making of boots and shoes for Cuba. Coals are imported directly from Great Britain for a cotton-factory and the steamship company, but in 1875 only three vessels entered the ports, with cargoes worth £1352. Mahon (q. v.) is the capital, and another chief port is Ciudadela. In recent years a large number of the inhabitants have emigrated to Algeria to avoid conscription and the oppressive taxes.

Min'orites. See FRANCISCANS, ORDER OF.

Min'os, a mythical king of Crete, son of Zeus and Europa, brother of Rhadamanthus and Sarpedon, and father of Ariadne (q. v.), who after death was made, with Æacus and Rhadamanthus, judge of the lower world. Legends later than Homer and Hesiod speak of another M., his grandson, and the husband of Pasiphae, who was killed by King Cocalus in Sicily, whither he had pursued Dædalus (q. v.). He was the lawgiver of Crete, and the first Greek who established a considerable naval power.

Min'otaur (Gr. 'bull of Minos'), in Greek mythology the monstrous offspring of Pasiphae, wife of Minos, and a bull, with a passion for which Aphrodite had inspired her. The M. was half man half bull, and was inclosed by Minos in the famous Labyrinth (q. v.) at Cnossus, where he fed on the youths and maidens yearly sent as a tribute by the Athenians, till slain by Theseus with the help of Ariadne (q. v.).

Minsk, a government of W. Russia, is bounded N. by Vitebsk and Vilna, S. by Volynien, W. by Grodno, and E. by Mohilev. Area, 35,254 sq. miles; pop. (1870) 1,135,588, of whom 185,000 are Poles, 97,000 Jews, and 3000 Tartars. M. is watered by the Pripiet and Beresina, affluents of the Dnieper, and is to the extent of three-eighths under forest and one-third pasture and meadow. Swamps, mostly in the S., cover 2204 sq. miles, and give rise to various diseases, including Plica Polonica.—**M.**, the capital, lies on the Swisloetz, a branch of the Beresina, and on

the Warsaw and Moscow Railway. It is the seat of a Greek archbishop and of a Roman bishop, and has 14 churches, a theatre, and a large corn trade. Pop. (1870) 35,563.

Min'ster (the Old Eng. form of the Low Lat. *monasterium*) properly denotes the church of a monastery, but is sometimes applied to a cathedral, e.g., to that of Canterbury by Robert of Gloucester. 'York Minster' is a familiar instance in the present day. Similarly, in Southern Germany, the *münster* of Strassburg, Basel, and Bein correspond to the *domkirchen* of Erfurt and Brunswick.

Mint (Old Eng. *mint*, Dut. *munte*, Lat. *mentha*, Gr. *mintha*), a genus of strong-scented perennial herbs, with creeping underground rootstocks, belonging to the natural order *Labiata*, and chiefly natives of N. temperate regions, though some are Australian. The species are very difficult to determine, and vary in number from 30 to 100, according to the discriminative power of the describer. Some are common in Britain, e.g., *M. aquatica* and *M. arvensis*, and among those of rarer occurrence are three of the most important as regards their uses, namely, Peppermint (*M. Piperita*), Penny-royal (*M. pulegium*), and Spearmint (*M. viridis*), but it is doubtful whether this last is really a native. Peppermint is extensively cultivated for the sake of its volatile oil, which is procured by distilling the leaves. The oil and the preparations made from it are largely used as aromatics, carminatives, and stimulants, and are especially useful in the alleviation of nausea, griping pains, and flatulence. Owing to its powerful taste, peppermint in some shape or other is frequently used to conceal the nauseous taste of medicine. A kind of liqueur is also prepared from it. The taste of *M. pulegium* is very peculiar, and to most people objectionable; its properties are similar to those of other mints, but in former times the plant had special virtues assigned to it, hence it is still employed as a domestic remedy in female complaints. *M. viridis* is the plant used for culinary purposes under the name of M. It possesses the properties of peppermint, but in a less degree.

Mint (Old Eng. *mynt*, from Lat. *moneta*, a surname of Juno, in whose temple at Rome money was coined), the place where coining or the processes employed in the manufacture of money is conducted. A coin may be defined as a piece of precious metal, impressed with a State device or mark, as a guarantee of its value and weight. British silver and bronze monies are merely tokens having a nominal value, and are issued simply for convenience in conducting petty business transactions. The early history of the coinage, and of the constitution of the M. in Britain is involved in obscurity. The Old English had silver and copper coins, but after the Norman Conquest the latter fell into disuse. There was no national gold coinage till the reign of Edward III., and the money then made consisted only of silver pieces of low value. Many foreign gold coins were, however, in circulation. In exchanging large sums it was customary to reckon by *weight* of bullion, while small sums were exchanged by means of the silver currency. Subsequently, and before the time of Henry VII., gold and silver coins of different denominations were gradually introduced, and by the period of the Restoration coins of gold and silver were very numerous, those of the latter metal being made of much higher value than formerly. Since then the varieties of coins have numerically decreased, and gold has been established by law as the only standard.

It would appear that in Old English times, the *mynters* ('minters' or 'moneys') formed part of the retinue of the king, and journeyed with him, striking money, when required, at his command. Gradually, however, as the amount of work increased, permanent mints were established in the chief towns. In Stephen's reign certain bishops, barons, and monasteries were privileged to coin money. Malpractices among the moneys in issuing debased coinage were frequent, and were visited with exemplary punishment. Relative to these frauds, an official, named the *gerth* (later *reeve*), is alluded to in Old English laws, and it is supposed that he was the responsible head of the M. at the time. Ruding observes that the London M. did not receive its full constitution of superior officers till the eighteenth year of the reign of Edward II., when a comptroller was appointed as a check upon the warden and master. The moneys were always a privileged class, enjoying exemption from certain taxes and public duties.

The Royal M., where the current coins of the United Kingdom and several of the colonies are struck, is situated at Tower Hill, London. At present (1877) its removal to the Thames Embankment is contemplated. In 1837, a Parliamentary Select Committee took evidence on the manner of conducting the business of the M., and in consequence of their report several important changes were made in its constitution. In 1851 the Royal M. became a governmental department, subject to the Treasury, and the practice of allowing contractors, or moneyers, to conduct the coinage was abolished. The remunerative office of Master of the M., of late years occupied by men of high scientific attainments, was abolished on the death of the late Master in 1869, and the nominal Master and Worker is now the Chancellor of the Exchequer. By Act 33 Vict., any person or importer may, under specified conditions, have gold bullion coined free of charge at the M., but since the Bank of England is bound by Act 7 and 8 Vict. to purchase bullion, previously weighed and assayed, at the rate of £3, 17s. 9d. per oz. of standard gold, it practically is the only importer. After coining, the Bank of England receives the gold at the M. price of £3, 17s. 10½d. per oz., whereby the Bank makes a profit of about £2000 on each million. The M. purchases silver for itself at the lowest market price. Act 56 Geo. III., ratified by Act 33 Vict., provides that the pound weight troy of standard gold contains 22 carats fine gold and 2 carats of alloy (copper), and that standard silver be of the fineness of 11 oz. 2 pennyweights of fine silver and 18 pennyweights of alloy in every pound weight troy; and it is further enacted that 20 pounds weight troy of standard gold be coined into 934½ sovereigns, and that 66 shillings be coined out of every pound troy of standard silver. While gold coin is thus issued at nearly the market value of bullion, a profit or *seigniorage* accrues to the M. from the silver coinage, for a shilling is intrinsically only worth about 10½d. This profit enables the M. to issue new silver coins for worn and light ones. All fees and profits of the M. are paid into the Exchequer.

Coining.—The processes pursued in coining silver and bronze, as compared with gold, differ so very slightly in detail, that it is only necessary here to trace the course of the latter. At stated times the Bank of England sends 'importations' of gold in the form of ingots, each of 180 oz. weight, and previously assayed, to the M. The ingots are there weighed and assayed, and the proportion of copper alloy or fine gold required to bring them to the fineness of standard gold determined. The ingots, with the ascertained alloy, are then melted and cast into bars. The plumbago crucibles, or melting-pots hold each a charge of 1200 oz., which fills four moulds. The bars formed in the moulds are removed and quenched with water, and from each bar two pieces are cut off for assay. If the assay prove satisfactory, the sovereign bars, measuring 24 inches long, 1·375 inches wide, and 1 inch thick, pass, after being weighed, to the *rolling-mill*, which reduces them to fillets 6 or 8 feet long. After the hollow ends are cut off, each fillet is formed into lengths of 18 inches, which are annealed in copper tubes, and then plunged into cold water. The fillets are further reduced in thickness by rolling, and on issuing from the *gauging-mill* they measure 1·829 inches wide and ·053 inches thick. At this stage a blank is now and again punched out of a fillet for comparison with a standard weight, a variation of half a grain only being allowed. Two inches of one end of each fillet are next pressed thinner, to the extent of one-third, in a *flattening-mill*, and after the whole length has been re-passed through the rolling-mill, the *flatted* end is introduced between two fixed cylinders in the *draw-bench*. The flatted part is there seized hold of by a 'dog,' which travels with an endless chain, and draws the whole fillet through the cylinders, to reduce it to a uniform thickness. The fillets are previously smeared with oil to prevent the excessive heat, developed by friction, destroying the surface of the fillet. On leaving the draw-bench the fillets are divided into four lengths, and from each a test-blank is stamped and weighed. The fillets, freed from oil, are then taken to the screw-cutting presses to be cut into blanks. The perforated metal is called *scissel* (Lat. *scindo*, 'I cut'), and returns to the melting-pot. The blanks then pass on to the weighing-room, where they are separated into 'heavy,' 'light,' and 'medium,' by marvellous automaton weighing-machines invented by Mr. Cotton and improved by Mr. Pilcher of the Royal M. These machines weigh at the rate of 23 blanks a minute, and indicate variations of 1/100th of a grain. As already mentioned, the law demands that 934½

sovereigns be taken out of 20 pounds troy weight of gold, which gives the weight of a sovereign as 123·2744 grains. Notwithstanding that the fillets are rolled and cut with mathematical exactness, the blanks are found to differ in weight. The law recognises the fact, and allows a *remedy* (from Lat. *ad remedium*) which is fixed by the Coinage Act of 1870 at two-tenths of a grain for the sovereign, and one-tenth of a grain for the half-sovereign over or under the standard weight. The medium blanks alone reach the coining-press, the others are re-melted. In a *marking-machine* or *edge-compressor*, the edges of the blanks are thickened by reducing the diameter. The raised edge affords a protection to the image and superscription to be afterwards added. After *annealing*, and *blanching* or brightening in boiling dilute sulphuric acid, the blanks are converted into coins in the screw *coining-press*. The obverse and reverse devices on the coins are obtained from the upper and lower dies (see DIE-SINKING), together with the *crenated* or *milled* edge from the collar, at one descent of the press. The perfect coins are put up into bags containing 701 sovereigns (180 oz.), and the weight and assays of several coins being tested, the Bank of England in due course receives the coinage.

English gold coins are legal tender to any amount, silver to 40s., and bronze to 1s. Bronze money (composed of copper 95, tin 4, and zinc 1, in 100 parts) is very much depreciated in value, and is struck principally at Birmingham, by Messrs. Heaton, under contract with the M. At a weight of 122·50 grains, or ·774 grain below the theoretical standard, current sovereigns reach the limit of 20s. value, and half-sovereigns cease to be legal tender for 10s. below 61·125 grains. On the return of worn gold coins to the M. a deduction is made for loss of weight below the legalised limits.

The coinage of the Royal M. for five years ending 1875 was as follows:—

	Gold.	Silver.	Bronze.
1871	£9,019,656	£701,524	£7,616
1872	15,261,442	1,243,836	47,413
1873	3,384,568	1,081,674	46,218
1874	1,461,565	890,604	65,632
1875	243,264	594,000	69,813

See Ruding, *Annals of the Coinage of Great Britain* (Lond. 1840), and G. F. Ansell, *The Royal M.* (3d ed. 1875).

Min'uet (Fr. *menuet*, from Lat. *minor*), the name of a slow, graceful dance. It is named from the *short* steps used in the dance. Properly, M. is the name of the music or air.

Min'ute, in Horology, is the 60th part of an hour; and in angular measurement is the 60th part of a degree. In architecture, it is the 60th part of the shaft of the column.

Minute is the name given to a draft of the procedure of any meeting, and is so called from its having been taken down *briefly*, with a view to its afterwards being *engrossed* or enlarged. In Scotch law a M. is a memorandum or record of some act of a court, or of contending parties.

Miocene (Gr. 'less recent') is the name given in geology by Lyell to the Middle Tertiary formations, coming between the Eocene and Pliocene. About 25 per cent. of its fossils are represented in living species. In Britain the M. is very poorly developed, and only in limited localities, Dartmoor in Devon, and Mull, off the W. of Scotland. On the Continent, all over Central Europe, there is an enormous development. It is divided into three well-marked subdivisions—the *Lower*, *Middle*, and *Upper*. The *Lower* is entirely a freshwater deposit, and consists of coarse conglomerates and sandstone. It is well developed in Switzerland (Molasse deposits), Croatia, Fontainebleau, Auvergne, and all through Germany; and its flora presents distinct subtropical characteristics. The *Middle* is somewhat marine, but has the same land-plants as the lower. It is very typical in Touraine, and also occurs in Switzerland, Madeira, Canary Islands, and the United States. The *Upper* consists of thin laminated marine marls and limestones, rich in fossil remains. 500 plants and 840 insects have been described by Heer from the Upper Molasse deposits of Switzerland. Its

flora strongly resembles the American types; and fishes and reptiles abound. The first fossil fox is here found, with remains of the *Dinotherium* and *Mastodon*. The sub-tropical climatic conditions, which the M. deposits imply, seem to have extended up to the 70th latitude, embracing the Faroe Islands, Iceland, and Greenland.

Mirabeau is the name of a family that during the 13th c. emigrated to France from Florence, and subsequently obtained the marquisate of M. in Provence. The one who has given it an undying interest is the great revolutionary orator, **Gabriel Honoré de Riquetti, Comte de M.**, son of Victor Riquetti, Marquis de M., who was born at Bignon, near Nemours, March 9, 1749, and came into the world a prodigy of size and ugliness. At the age of three his ugliness was increased by smallpox. The child was impish in habits as well as looks, exhibiting such terrific activity in mind and body that his father—rather heedlessly, for he was corresponding with the uncle—likened him to ‘a nephew of the devil.’ No child had probably a worse upbringing. Victor Riquetti was a domestic tyrant of the maddest kind, who wrote philanthropic and economic pamphlets, and called himself *L’Ami des Hommes*, but who treated his wife and children with unspeakable cruelty. In the course of his life he caused to be issued against them no fewer than fifty-four *lettres de cachet*. M. was placed under a succession of tutors who could not manage him; he was then entered in the liern regiment of the Marquis de Lambert, and henceforth his career till the outbreak of the Revolution is a miserable record of vicious indulgence, varied by imprisonment, attacks of disease, and the production of literary essays. Most of these are necessarily valueless, for M. was not in any sense a scholar or a student; but his *Traité de la Mythologie*, *Traité de la Langue Française*, *Essai de la Littérature Ancienne et Moderne*, may still possess an interest as the work of a man whose name cannot be forgotten in the history of France. His *La Monarchie Prussienne sous le Frédéric le Grand* (1788), and *Histoire Secrète de la Cour de Berlin* (1789), are the result of a temporary refuge in Prussia. But it was not till 1789 that the passionate and powerful genius of M. found fit expression. Rejected by the nobles of Provence as their representative, he suddenly denounced the order as ‘in all countries and in all ages the enemies of the people,’ and threatened them with the vengeance of another Marius. Elected by the Third Estate as *député* for Aix and Marseille, the moment he appeared in the Assembly he took the foremost place by the fire and thunder of his eloquence. On the memorable 23d of June, when De Brézé entered the Assembly with the king’s orders for them to depart, M. bellowed through the tempest of voices: ‘Go, tell those who sent you that we are here by the will of the nation, and that nothing but the force of bayonets can drive us hence!’ Yet he detested the mere anarchy of mobs, and to prevent insurrection instituted (8th July 1789) the National Guard. Gradually the Court drew towards him in its feebleness and despair, and the brief remainder of his life was spent in an effort, hopeless indeed, but carried on with dauntless resolution and indomitable will, to restrain the ever-increasing madness of the Revolution, and to force upon the nation some form of constitutional life and some wreck of royalty. It is a striking tribute to the greatness of his character and the splendour of his eloquence, that, without allies and without followers, he ruled imperiously the fiercest and most lawless Assembly that has ever met in the history of mankind. On the 1st of February 1791 he took his place as President of Assembly; but the excesses of passion had consumed him; for a few weeks he struggled on, his spirit aflame, his body a mass of corruption, till the 27th March, when, after speaking five times, he left the Assembly for ever. He died on the 2d of April. His numerous works are most completely collected in the edition of 1825–27, 9 vols. The best book upon M. is Dumont’s *Souvenirs sur M.* (Par. 1832). See also *Mémoires Biographiques*, &c., edited by Lucas de Montigny (8 vols. Par. 1834); Vernorel’s *M., sa Vie, ses Opinions, ses Discours* (5 vols. Par. 1864); and Reynaud’s *M. et la Constituante* (Par. 1872).

Mir’acle (Lat. ‘something wonderful’) is a name which has been used in a very loose sense for ‘anything wonderful, anything for which the proximate cause could not be discovered, and anything in which divine agency was specially indicated.’ More strictly it is defined as ‘an event in the external world

brought about by the immediate efficiency or simple volition of God.’ According to Christian teaching generally, a miracle is ‘an incident accomplished in opposition to the laws of nature, in the name and by the interposition of the Deity, who thus manifests his will to humanity, and particularly for the purpose of establishing the truth of a doctrine’ (cf. Matt. ix. 2–8; John xi. 15, 42, 45). The principal question connected with miracles is their value as a proof of a divine revelation. It has been maintained, on the one hand, that miracles are the only satisfactory evidence of a divine revelation; on the other, that they are neither necessary nor available, because, ‘as faith must be founded on the truth as truth, it is impossible that any amount of external evidence can produce faith, or enable us to see that to be true which we could not so apprehend without it.’ The view held by the more moderate theologians is that the evidence of miracles is important and decisive, but at the same time subordinate and inferior to that of the truth itself; in other words, that ‘the point which miracles are designed to prove is not so much the truth of the doctrine taught as the divine mission of the teacher.’ (1) It is held to be a sufficient proof of the validity and importance of miracles as seals of a divine mission, that as a fact God has confirmed his revelations by them. (2) The sacred writers appealed to miracles as proofs that their message was from God. Thus, in the Acts of the Apostles it is stated that the testimony of the apostles was confirmed by divers wonders and miraculous gifts, and that Christ himself was approved by miracles, and wonders, and signs (Acts ii. 22, 43, &c.). (3) Christ constantly appealed to his miracles as a proof of his divine mission (cf. John v. 20, 36; x. 25, &c.).

The objections which have been urged against miracles are legion. 1. It is objected that they, as generally defined, ‘involve a suspension, or alteration, or violation of the laws of nature,’ which laws are absolutely immutable, so that miracles are impossible. 2. With others the objection goes farther back, and the possibility of miracles is denied by (1) Pantheists, who affirm that there is no distinction between natural and supernatural events; (2) by those who hold that miracles, as supposing separate individual acts of the divine will, are inconsistent with the nature of an absolute Being; and (3) by those who hold that ‘if God interfere in the natural order of events which are produced by causes which he has ordained, it can only be on account of the imperfection of his work.’ 3. Again it is objected that it is impossible to know when an event is miraculous or when it is due to natural causes, since we have not a perfect knowledge of the power of such causes, and more especially as according to the Bible ‘lying wonders have been wrought by evil spirits, through the medium of magicians and false prophets’ (Exod. vii. 11, 12, 22, viii. 7; Deut. xiii. 1, 2; Matt. xxiv. 24), which are real miracles in the sense of not being due to natural causes. 4. One of the most formidable objections is Hume’s famous one, that no human evidence is sufficient to establish the occurrence of a miracle, since, according to our twofold experience, it is more probable that the witnesses should be mistaken than that the course of nature should have been violated.

An important question connected with the belief in miracles is the time when miraculous powers ceased to be granted to men. According to the Acts of the Apostles, after our Lord’s ascension, they were poured out on the Apostles. The continuance of those powers in the primitive church is alleged by divines of all churches as a proof of the divinity of the Christian doctrines. The most prevailing opinion among Protestant writers is that they ceased at the beginning of the 4th c., being withdrawn, as no longer needed, when Christianity was established in the Roman Empire (325). According to other writers, who give copious ‘proof’ of their statements, they were continued to the 5th c., to the 6th c., and to the Reformation. That they have been continued to the present day is maintained and believed to be proved by the most respectable testimony in the Roman Catholic Church. See Middleton’s *Inquiry into the Miraculous Powers*, &c. (Works, 1755); Balhage’s *Bridgewater Treatise* (1838); *Essays and Reviews* (Lond. 1861); Mozley’s *Bampton Lectures* (1865); Hodge’s *Syst. Theol.* (Edinb. 1873).

Miracle Plays. See MYSTERIES, MIRACLE PLAYS AND MORALITIES.

Mirage (Fr., ‘something seen as in a mirror’) is a peculiar optical phenomenon, occasioned by certain atmos-

pheric conditions. It is very often seen by travellers in the heated sand plains of Lower Egypt, and by mariners in high latitudes. In the former cases the air close to the strongly heated ground is rarefied so as to become less dense than the higher strata. The great tranquillity of the atmosphere permits this state of things to continue for some time, and consequently rays of light in passing down through the lower strata of air, which are becoming less and less dense the nearer they are to the ground, are suffering continual refraction, so that they travel in curved lines, which tend ultimately to turn up. Now the direction in which any object is seen is the direction in which the rays from the object enter the eye, and hence, under certain conditions like those above indicated, a cloud at a considerable altitude in the sky may really be seen projected on the ground like a lake. The corresponding marine phenomenon, commonly called *looming*, is similarly explained, though the conditions are reversed. Here the density of the air increases as we approach the chilly surface of the sea, and hence the light-rays travel in arches whose vertices point upwards. A vessel below the visible horizon of the spectator is thus frequently seen projected on the sky at a considerable elevation. As a rule there are more images than one visible, which are alternately reversed and erect, and this is fully explained by the consideration that the gradual variation in density, and therefore in refractive index of the vertical column, may render possible several distinct trajectories of rays terminating at the points. The Fata Morgana (q. v.) of the Straits of Messina is explained upon the same principles.

Miramichi, a river in the province of New Brunswick, Dominion of Canada, flows in a N.E. direction, and, after a course of 200 miles, discharges itself by a wide estuary into the Gulf of St. Lawrence. It is navigable for large ships to Newcastle, and has a large export trade in timber. The salmon and cod fisheries at its mouth are valuable.

Mir'amon, Miguel, born in the city of Mexico, September 29, 1832, entered the military academy of Chapultepec (1846), and received his commission (1852). He opposed the revolution of 1855, defeated Juarez at Salamanca (1858), and was appointed president *ad interim* in the room of Zuloaga (1859). He failed in an attack on Vera Cruz, and, exonerated for his share in the 'massacre of Tacubaya,' was forced (1860) to take refuge in Europe, where he visited the French, Spanish, and Italian courts. On the accession of Maximilian (q. v.) to the throne of Mexico, M. was made grand-marshal (1863) and ambassador to Berlin (1864); but in 1866, on the withdrawal of the French troops, he hastened back to Mexico, and undertook the defence of Queretaro, which was captured May 15, 1867. Along with Maximilian and Tomas Mejia, M. was tried by court-martial, sentenced, and shot on the Cerro de las Campanas, June 19, 1867.

Miran'dola, a town of N. Italy, pr vince of Modena, in a flat, rice-growing district, 45 miles N.W. of Bologna. It has a fine cathedral, and an old palace of the dukes of M. and Concordia, who belonged to the famous Pico family. Francesco Maria sold the duchy of M. to Modena in 1710. Pop. (1874) 13,170.

Mire'court, a town in the N.E. of France, department of Vosges, 17 miles N.W. of Epinal. It is the centre of a lace manufacture which extends 12 miles in every direction. There are also manufactures of musical instruments, leather, hosiery, and embroidered articles. Pop. (1872) 5089.

Mirr'or (Fr. *miroir*, from Lat. *miror*, 'I wonder, I admire'), a looking-glass, or an instrument with a highly polished surface capable of reflecting the image of objects presented to it. Hand mirrors of polished metal have been in use from the earliest times. The Egyptians made them from copper, the Romans, during the empire, from silver chiefly, and a kind of white metal is still used in the East. Golden mirrors are mentioned by ancient writers, but Beckmann (*History of Inventions*) gives it as his opinion that this precious metal was only used for the M-frame. Ancient mirrors of obsidian and other stones are believed by the same author to have been made rather for ornament than utility. Pliny states that glass mirrors backed with leaf-metal were made at Sidon; metal mirrors were not, however, superseded by glass in Europe till the 13th c. Polished plate-glass

(see GLASS) silvered on the reverse surface is now exclusively employed for mirrors. An amalgam of tin was used in 'silvering' down to 1840. Drayton, an English chemist, then devised a method of coating the glass with a thin layer of silver precipitated from an ammoniacal solution of nitrate of silver by means of highly oxydisable essential oils. Tartaric acid has since been substituted for the latter. The glass is well cleaned and heated, and in an hour and a quarter after the solutions of silver and tartaric acid have been poured on the glass, the silvering is effected. The process is completed by washing the glass with water, and after drying, applying varnish to protect the silver from friction. M. Lenoir has recently discovered that by sprinkling a dilute solution of the double cyanide of mercury and potassium over the silver after washing, that an amalgam, whiter than pure silver, more adhesive to the glass, with less affinity for sulphur vapours, is instantly produced.

Mir'za, a contraction of the Persian 'Mir-zadeh,' i.e., son of a pince. Appended to the surname it is the title of a prince; pruned, it is a common style of honour.

Mirzapore ('Prince-town'), the chief town of the district of the same name, in the N.W. Provinces, British India, on the left bank of the Ganges, and a station on the railway, 448 miles N.W. from Calcutta, and 53 E. from Allahabad: pop. (1872) 67,274. It is a town of modern date, with numerous mosques, temples, and *ghauts*, or bathing-places. It was formerly the cotton emporium of Central India, before the days of railways; and still conducts a large trade both by river and rail. In the year 1876 77 the principal exports were thus returned: Raw cotton, £45,000; oil-seeds, £80,000; stone, £16,000; sugar, £26,000. The import of European piece-goods was valued at £148,000. The exports down stream during the first six months of 1876 were valued at £32,000, chiefly stone and cotton. There are manufactures of carpets, cottons, and silk. The military cantonments are 3 miles N.E.—The district of M. lies between the native states of Bundelcund, the Behar district of Shahabad, and the Gauges: area, 5217 sq. miles; pop. (1872) 1,015,826. The crops are wheat, barley, millets, sugar-cane, and cotton. The sandstone of Chunar is extensively quarried. Other products are *kunkur* limestone, saltpetre, iron, and slate.

Misdemean'our (from *mis*, 'wrongly' or 'astray,' and *demeanour*, from Fr. *démener*, 'to lead' or 'drive'). The term is generally used in law in contradistinction to Felony (q. v.), and comprehends all offences which do not amount to felony. Every infringement of a public statute is a M., though no penalty for infringement be stated.

Misere're (Lat. 'Have mercy upon me'), the familiar name in Catholic usage of the 51st Psalm (50th in the *Vulgate*). It is one of the 'Penitential Psalms,' and occurs very often in the services of the Catholic Church, nowhere so impressively as in the office of the *Tendré* in Holy Week.

Miserere (in Fr. *miséricorde*, or *patience*), in mediæval choir-stalls, was a projecting bracket, often elaborately carved, affixed to the under side of the seat, which, the seat turning on hinges, was designed to form a rest for the occupant of the stall during the standing portions of the service.

Misfeasance (Fr. 'a wrong-doing') is a law term denoting the doing of a wrong. *Nonfeasance* is the omitting to do that which should have been done.

Miseno, Capo di, a promontory on the W. coast of Italy, 91 miles W.S.W. of Naples. Here stood the ancient *Misenum*, whose harbour was, under Augustus, made the station for the Tyrrhenian fleet.

Mish'mi Bitter is 'a stomachic and tonic much used in Bengal, and is derived from the golden-yellow, woody root of *Coptis Tetra*, a small, stemless plant, found in the Mishmi Mountains, E. of Assam. The bitter rhizomes of an American species are also used for a like purpose. See COPTIS.

Mish'na (Heb. 'learning,' from *shanah*, to learn, to repeat, although by the Christian fathers it was translated *deuteriosis*, as if from *sheni*, second [sc. law]) had its origin in traditional glosses upon the Law. It was the work of the 'Scribes' of the Great Synagogue (B.C. 530-220) to preserve the text, to explain its precepts in accordance with collateral tradition, and to in-

struct the people in the synagogues and the schools. For the better keeping of the old precepts they erected also certain 'Fences,' or new injunctions. Next came the Scribes of the Sanhedrim (B.C. 220-220 A.D.), and at the end of eight hundred years, the ordinances, injunctions, prohibitions, precepts—old and new, traditional, derived, and enacted—had grown to such bulk that they could no longer be mastered in their scattered and chiefly unwritten form. The reduction of the whole unwritten law into a code was accomplished about 220 A.D. by the combined efforts of all the schools, under the superintendence of Rabbi Jehuda the Hoily. See E. Deutsch's *Lit. Remains*; art. 'Talmud' (Lond. 1874).

Miskolcz, a town of Hungary, county of Borsod, in the rich wheat-growing valley of Sajó, 95 miles E.N.E. of Pesth by rail. It has a handsome Protestant Church and a theatre, and a large trade in wine, melons, &c. Pop. (1869) 21,199.

Misno'mer means in law the misnaming of a person. Formerly, in a criminal indictment, an error in the name of a defendant was fatal to it. But when this occurs the Court is now by statute required to amend the indictment, and the case proceeds accordingly.

Misprision and Contempt are terms in law denoting those offences next under the degree of treason or felony. M. of felony is the concealing of it without assenting to it.

Misrepresentation is in law the kind of falsehood which the law punishes or gives redress for. See LIE; PERJURY; TRADE MARKS, FRAUDS IN; INSURANCE; DIRECTOR.

Miss'al is a book containing all that is required for the celebration of the Mass (Lat. *Missa*), that is, the fixed 'ordinary' and 'canon,' with the changeable Introits, Collects, Gospels, Epistles, &c. With the object of introducing uniformity in place of the almost endless variations which had been in use up to the Reformation, by a decree of the Council of Trent and a bull of Pope Pius V., the Roman M. was in 1570 prescribed for use in all churches, except those which had one of their own for two centuries. The M. is a development of the ancient Sacramentaries.

Missionary are expeditions sent into infidel countries for the propagation of religion. Such expeditions, in one form or another, have been sent out in connection with all religions possessing any degree of vitality, e.g., the Buddhist and Mohammedan. The present article deals solely with the M. of the Christian Church.

1. **Early M. of the Church.**—The first missionaries were of course the apostles, and their successors laboured unremittingly till the Christian religion was established as the state religion of the Roman empire (325). After that event the Church was in a position to direct her efforts farther afield. In 348 a converted Goth of the name of Ulilas was consecrated a bishop, and sent to convert his countrymen, a work in which he was very successful, part of the fruit of his labours being a Gothic version of the Scriptures. Christianity is said to have been introduced into Ireland in 431 by St. Palladius, who was followed by St. Patrick in 440. From the Church which was founded in Ireland M. were sent to Alban (afterwards part of Scotland) (see ST. COLUMBA), and to the tribes of Germany and the N. of Europe. Christianity was unquestionably introduced into Britain during the time it was held by the Romans, but was extinguished by the invasion and conquest of the heathen Germans, except in Wales. A mission was sent to the country by Pope Gregory the Great, 597. Augustine, the leader of it, was consecrated Bishop of the English, and then Archbishop of Canterbury, and the Christian religion was speedily re-established in the country. About the same time Columbanus, an Irish monk, introduced Christianity into Burgundy, and after he was banished from the country continued his labours among the Alps and Apennines. After his death (615) St. Gall and St. Kilian continued the work in Switzerland, Suabia, and Franconia. Christianity was introduced into N. Germany early in the 7th c. by Amandus, and into Holland by St. Eloy, and the English bishops Wilfrith (677) and Willebrod (692). The great missionary of this time was St. Boniface (q. v.), who laboured in Germany for forty years (715-755). A Frankish mission was sent to Denmark about 825 under Ebbo, Archbishop of Rheims, and another soon after under Ansgar (q. v.), the 'Apostle of the North,' who also went to Sweden (about 830). The Christianity of these northern countries, which

had become almost extinct, was revived in the 10th c. and 11th c. by English missionaries, who also went to Norway and Iceland. A country which seems to have attracted M. to it at a very early period is India, whither Christianity is said to have been first carried by St. Thomas. M. are said to have been sent to it from Alexandria about the end of the 2d c. and the beginning of the 4th c., and one seems to have been sent from England in the reign of Alfred.

II. **Modern M.**—After the 11th c. missionary effort slumbered till the great awakening of the Reformation. Since then it has been increasingly active. We may note (1) *Roman Catholic M.*—The discovery of America opened up a new field for missionary enterprise, and the Church everywhere followed up the conquest of the country by the Spaniards. At this time also the great missionary organisation of the Jesuits (q. v.) was formed. Francis Xavier (q. v.), one of Loyola's associates, went to India in 1542, where he produced a reformation among the European settlers, and baptized the natives by tens of thousands, repeating the work in Ceylon, whither he went in 1547. He then went to Japan, where he laboured for three years, and founded a mission which produced extraordinary fruits. Although Xavier did not succeed in penetrating into China, the Jesuits afterwards accomplished it, and met with great success. For the more systematic working of M. a congregation of cardinals was appointed at Rome in 1622—the Congregation de Propaganda Fide—which is the most perfect missionary organisation in the world. (2) *Protestant M.*—Missionary effort in the Church of England was revived in the 16th c., as in the case of Spain, in connection with voyages of discovery and the foundation of colonies. It was a principle of the time 'that the Church should be planted on all ground which was taken possession of in the name of the Crown.' The Church was accordingly established in the North American colonies, and a society for the promotion of Christianity among the Indians was incorporated in 1649. The Society for the Propagation of the Gospel in Foreign Parts, which was founded in 1668, was incorporated in 1701 under the name of the Society for Promoting Christian Knowledge, and in the beginning of the 19th c. the Church Missionary Society was originated. Other societies are the Baptist Society (founded 1792), the London Missionary Society (1795), which, at first supported by English Protestants generally, has now been left in great measure to the Independents. The Wesleyan Methodist Missionary Society was formally established in 1818. The Churches in Scotland—Established, Free, United Presbyterian, &c.—have all their missionary societies. The great American society, although by no means the only one, is the American Board of Commissioners for Foreign M., which was established in 1810. But the Church which perhaps deserves the title of missionary above all others is the Moravian, which established M. to the Hottentots (1736), on the coast of Guinea (1737), in S. Carolina and Algiers (1739), in Ceylon, Amsterdam, &c. Within the last fifty years missionary work has made a great advance, and its present position is briefly as follows:—*Africa.*—The northern coast is practically untouched, being wholly Mohammedan. M. begin at Senegal, and along the W. coast are many M. more or less prosperous, founded by the Wesleyan, Church of England, American Presbyterian, United Presbyterian (Scotland), the Basel, and the Baptist Societies. In South Africa, where the greatest conquests have been made, there are about 450 missionaries, and 90 native labourers. In Egypt the most prosperous M. belong to the American United Presbyterian Church. In Madagascar, where Christianity is now the established religion, there are M. belonging to the London, the Propagation, and the Norwegian Societies, as well as that of the Society of Friends. In the Island of Mauritius the M. belong to the Church of England. *Asia.*—In Turkey, Syria, and Persia, there are M. belonging to the Church Missionary Society, the American Presbyterian Board, the American United Presbyterian Church, &c. In India and Ceylon M. were carried on in 1872 by 35 Missionary Societies, besides local agencies, with 551 ordained missionaries, besides native labourers. In China there are about 30 agencies at work, with about 200 ordained missionaries, half of whom come from the United States. In the Indian Archipelago and the Straits the M. belong principally to the Dutch, Rhenish, Gossner's, and Propagation Societies. In Polynesia M. have been very successful. Within the last fifty years more than 300 islands have cast off idolatry. *America.*—The great mission fields here are

Mexico, S. America, and the W. India Islands. Several societies, British and Canadian, especially the Wesleyan and Church of England societies, are at work among the Indians in the British Possessions.

In 1871, according to Dr. W. Butler, there were throughout the world 2165 Protestant missionaries, 2078 female missionaries, and 9886 native preachers and catechists. In 1874 the receipts of the various missions in Great Britain amounted to £872,906, in Continental Europe to £110,965, in America to £472,508. See Dr. Maclear's *History of Christian Missions During the Middle Ages* (Lond. 1874), and Hassell's *From Pole to Pole* (Lond. 1874); also article BIBLE SOCIETY.

Mississippi (Ind. *Missi-Sippe*, 'great river'), the principal river of N. America, and after the Amazon, and perhaps the Congo, the mightiest in the world, rises in Lake Itasca, on the densely-wooded plateau of Minnesota, to the W. of Lake Superior, and at an elevation of 1680 feet above the sea. Its course is southerly, and its length in a straight line is 1164 miles, but with its windings 2800. It has a drainage area of 1,244,000 sq. miles, an extreme depth of 120 feet, and a mean velocity of 3'39 feet per second. The M. enters the Gulf of Mexico, after pushing forward a long tongue of land, by three main 'pas-es,' respectively 1677, 1440, and 900 ket wide. Till it reaches the Missouri (q. v.) it flows through a broken picturesque country of heath and pine forest, its narrow course in parts confined on either side by carboniferous bluffs 200 feet high, and impeded by numerous rapids, of which the chief are the Falls of St. Anthony (18 feet), the Des Moines Rapids (24), and Rock Island Rapids (22). Below the Missouri, or 1300 miles from its mouth, its basin entirely changes character. Here the enormous stream rolls through a rich, level, alluvial bed, mostly covered with forests on the E. bank, and stretching away to the W. in boundless prairies. The M. is subject to most destructive annual floods, to guard against which vast levees have been constructed at the cost of the valley States. Louisiana alone has erected, on its 780 miles of river-front, 73,000,000 cubic yards of earthworks. The new levees (1873) are 22 feet high, 142 at the base, and have a cross section of 1672 sq. feet. An appeal is now (1877) being made to the United States Congress to take over the entire care and cost of the works, and a recent estimate by United States engineers gives the cost of a complete system at \$30,000,000, and of the yearly repairs at \$2,000,000. The maximum rise of the river at Natchez, Vicksburg, and Cairo, respectively 370, 480, and 1007 miles distant from the mouth, is 52 feet. The delta, formed by sediment brought down chiefly by the Missouri, is much larger than that of any other river, having an estimated area of 38,600 sq. miles. Besides the Missouri, the M. receives the Red River, Yazoo, Arkansas, Ohio, and an immense number of other navigable streams. It passes New Orleans, Natchez, Vicksburg, Memphis, St. Louis, &c., and is navigable for great river-steamers as far as St. Anthony, 2037 miles.

Mississippi, a southern state of the American Union, bounded W. by the rivers M. and Pearl, E. by Alabama, N. by Tennessee, and S. by Louisiana and the Gulf of Mexico. Area, 47,156 sq. miles; pop. (1870) 827,922, of whom 445,026 are coloured. The country, entered in the N.E. by the limestone spurs of the Appalachians, has a general slope W. and S., and is roughly divided into three districts. (1) The great cotton-zone in the N.W., comprising some 4,000,000 acres; (2) a fertile prairie region in the W., yielding rich crops of corn and cotton; and (3) the southern and sparsely inhabited portion stretching to the Gulf, with its inferior soil, its fine pasturage, and its vast 'pine barrens,' from which are drawn immense supplies of timber and turpentine. The principal rivers are the great western boundary stream, its affluents the Homochitto, Big Black, Yazoo, Sunflower, and Tallahatchie, and the Pearl and Pascagoula, flowing directly to the Gulf. M. has a coast-line of 88 miles, and includes a group of islands, of which the chief are Horn, Deer, and Ship, the last possessing the only good coast harbour of the state. The prevailing rocks are limestones and clays belonging to the Devonian, Cretaceous, and Tertiary formations; the minerals are few and of comparatively little value. The climate is singularly healthy, except in the low bank river-bottoms. In 1873 observations at Vicksburg gave a mean temperature of 64.67°, and a rainfall of 48.4 inches. A great part of the surface is still covered with primeval forests of oak, black walnut, hickory, beech, sycamore, cottonwood, pine, &c., and like the other Gulf

States M. is prodigal in rare fruits and beautiful flowers. About one-seventh of the entire area has been brought under cultivation, and only some two-fifths were included in farms in 1870. Cotton, of which it produces more than any other state, was almost the exclusive staple for many years, but latterly much attention has been paid to other crops. In 1873 the amount of cotton raised was 600,000 bales (value \$28,500,000); of Indian corn, 18,543,000 bushels (value \$15,761,550); of wheat, 189,000 bushels; of oats, 492,000; of Irish potatoes, 206,000; of tobacco, 85,000 lbs. (value \$14,450); and of hay, 13,000 tons. Minor crops are sugar, rice, and sweet potatoes. In 1874 M. had 88,300 horses, 99,100 mules and asses, 180,100 milch cows, 329,800 oxen and other cattle, 153,600 sheep, and 819,100 swine—value, \$29,000,000. The industries are very slight, there being only (1873) 156 timber saw-mills, 45 flour-mills, and 11 cotton factories. In 1875 the railways extended 1141 miles. Jackson is the capital, but the chief towns are Vicksburg, Natchez, and Columbus. First visited by Fernando de Soto in 1539, the country was partly explored by Marquette and Joliet in 1673. A colony of 200 French immigrants was founded on the Bay of Biloxi in 1699. The territory was acquired in 1718 by the projectors of the M. Scheme (q. v.). Admitted to the Union in 1819, it was one of the first Southern States to secede in 1861, and during the Civil War it was the scene of many destructive raids and battles. The siege and capture of Vicksburg in 1863 by General Grant was one of the great events of the struggle. Since the war there has been a great decrease in the value of property, and the average price of farm-land is still only some two-fifths of what it was before 1860.

Mississippi Scheme, the name of a great financial 'bubble,' projected in Paris in 1719 by John Law (q. v.), in conjunction with the regent and officers of the State. Its ostensible object was to develop the resources of Louisiana province, the basin of the Mississippi, but its real purpose was to relieve the exchequer from the debts incurred by the wars of Louis XIV. Already director-general of the royal bank, Law was placed at the head of the so-called 'Company of the West,' which received a grant of Louisiana, and issued 200,000 shares at 500 livres each. Paper currency was accepted, although then depreciated to 70 per cent. below par. Subsequently the company acquired a monopoly of almost the entire foreign trade of France, and the power of collecting national revenue and taxes. The shares were increased to 624,000, and meanwhile the bank issued its notes freely till the paper currency amounted to 2,700,000,000 livres. The whole nation was in a frenzy. Crowds from all parts rushed to Paris. Here the streets were thronged by excited mobs, and trade for the time was increased enormously. The climax was reached when at the end of 1719 the shares were sold for 10,000 livres each, and money was so plentiful that the bank loaned at 2 per cent. Soon after this came the crash. Attempts to restrict the issue of gold led to a rush upon the bank. Vast but ineffectual efforts were made to restore confidence. The company was even amalgamated with the royal bank. But the bubble was finally burst by an edict of 21st May 1720, announcing a reduction of one-half in the value of shares and bank-notes. In July 1720 the bank stopped payment, and the inevitable result was universal distress and bankruptcy. The leaders in the scheme are charitably allowed to have been themselves deluded by the notion that the prosperity of a nation can be secured by a mere increase of its money circulation, and that the stability of paper money may be guaranteed without respect to its convertibility.

Missive, in Law, is a letter or memorandum. In mercantile affairs a M. may have the effect of a legally executed document.

Missolonghi, a fortified seaport of Greece, in the nomarchy of Acarnania and Ætolia, stands on a promontory in the shallow Gulf of Procoponista, 12 miles N.W. of Patras. The fisheries, its principal industry, employ 300 men, and are let by the Government at an annual rental of £53,000. The anchorage for larger ships is at San Sosti, 6 miles distant. In 1873 there entered the port, 1212 vessels of 59,568 tons; and cleared, 1184, of 59,285 tons. The value of exports (currants, valonia, wool, tobacco, &c.) was £17,857; and of imports (coffee, sugar, wheat, iron, &c.), £28,571. Pop. (1870) 5714. M. is famous for the part it played in the Greek War of Independence, when Maurokordatos successfully defended it from November 5, 1821, till January 6, 1823, and again for fifty-nine days in the close of the

latter year. But on April 22, 1826, it was taken by Reshid and Ibrahim Pashas, with a force of 20,000 Turks and 14,000 Egyptians, after a twelve months' gallant defence by Notos Bozzaris and his garrison of 4000 men. A mausoleum enshrines the heart of Byron, who died here, April 19, 1824. See Tabre, *Histoire du Siège de M.* (Par. 1826).

Missouri ('mud-river'), a river of N. America, which rises in the Rocky Mountains, hardly $\frac{1}{2}$ mile from the source of the Columbia. It is formed from three rivers, the Jefferson, the Madison, and the Gallatin, runs first N., and after several considerable falls, turns E., then flows S.E. till below St. Louis it reaches the Mississippi, after a course of 3047 miles. The chief affluents of the M. from the right are the Yellowstone, Little M., White River, Nebraska, and Kansas; from the left, Jacques, Big Sioux, and Little Sioux. It is navigable for steamers as far as the falls, near the Rocky Mountains. The basin of the M. is about 557,918 sq. miles.

Missouri, a central state of the N.-American Union, bounded N. by Iowa, W. by Nebraska, Kansas, and the Indian Territory, S. by Arkansas, and E. (470 miles) by the Mississippi, which separates it from Illinois, Kentucky, and Tennessee. Area, 65,350 sq. miles; pop. (1870) 1,721,295, of whom 118,071 are coloured and 75 Indians. The state is crossed from W. to E. by the M. River (q. v.), which is also for 200 miles its N.W. boundary. The S.E. is swampy, the S.W. chiefly covered by the Ozark Mountains and their offshoots to the river Osage. Most of the rest is rolling prairie, with here and there forests, which in the M. valley are especially luxuriant. Coal measures extend over 23,100 sq. miles of the W., N.W., and N.; adjoining these, and in the S.W. and N.E. of M. are found Devonian rocks; E. of the latter is a Silurian tract 200 miles broad; and the S.E. is chiefly alluvium and drift deposits. M. is particularly rich in iron ores. Lead and zinc (in the S.) are plentiful, and copper, nickel, and cobalt, are also worked. The soil is generally fertile, though less so in the S.W. and S. The wild animals of M. are very numerous, including the bear, panther, wolf, racoon, and opossum; deer, rabbits, hares, squirrels; the eagle, vulture, and other birds of prey. The climate is one of extremes, ranging at St. Louis from 7° to 100° F., and the average rainfall amounts yearly to 37.83 inches. In 1873 the produce of Indian corn was 70,846,000 bushels, valued at \$26,921,480; of wheat, 11,927,000; rye, 446,000; oats, 15,670,000; barley, 266,000; buck-wheat, 20,000; Irish potatoes, 1,839,000; tobacco, 13,200,000 lbs.; hay, 101,000 tons (worth \$5,700,500). The live-stock of M. consisted in 1874 of 543,000 horses, 89,200 mules, 421,400 milch-cows, 806,300 oxen and other cattle, 1,408,500 sheep, 2,603,300 swine—total value, \$67,306,342. In 1870 the value of flour produced in M. was \$28,332,160; packed meats, \$13,933,195; liquors, \$8,371,440; lumber, \$6,685,462; tobacco and cigars, \$10,415,604. The value of all industrial products was \$206,213,429. The lead produced in 1873 was 27,676,320 lbs.; zinc, 11,582,440 lbs.; the iron in 1872, 509,200 tons. The value of the total annual product of the mines of M. is estimated at \$14,000,000. In 1875 there were 2600 miles of railway. M. publishes 280 newspapers. St. Louis is the largest town, Jefferson the state capital. Other cities and towns are Kansas, St. Joseph, Hannibal, St. Charles, Springfield, Ledalia, and Lexington. Though as early as 1864 there was a small French colony at Fort St. Louis, the colonisation of M. properly began only with the 18th c. M. belonged to Louisiana, came under Spain in 1763, and in 1803 under the Union. In 1812 it was constituted a territory, in 1821 was received as a state. Slavery, though never extensive in M., contributed to retard its progress. In the struggle for Kansas the slave-owners seized a large part of M., and at the beginning of the Civil War sought to attach it to the South. Since the abolition of slavery, progress of every kind has been very great. The state sends thirteen members to the House of Representatives.

Mistake, in Law. See ERROR IN ESSENTIALS; CONSENT; CONTRACT.

Mistletoe (Old Eng. *misteltid*, Ger. *mistel*, Icel. *mistleinn*, of uncertain derivation) is the name of a genus of parasitic plants designated botanically *Viscum*, and to most European nations familiarly represented by the common M. or *V. album*. The natural order to which it belongs is *Loranthaceæ*, consisting of about 450 evergreen parasitic shrubs, chiefly tropical

in their distribution, but many found in temperate regions. The above-named *V. album* is the only species of the genus possessed of any considerable interest, and about it only a few points of the scientific, historic, or legendary literature can here be noticed. It roots firmly, grows slowly, gradually kills, and so ultimately dies itself upon the tree-branch that supports it. The stem when full grown is an inch or more in thickness, and divides and subdivides in a regular forked manner; the leaves are opposite, oblong, leathery, and of a yellowish-green colour; the separate male and female flowers are inconspicuous, and the fruit forms a small white berry with viscid contents. It has a marked preference in the selection of the tree it grows upon, the apple being most commonly affected, then poplars, hawthorn, limes, maples, mountain-ash; it is rarely found on the oak (less than ten authentic instances are recorded in Britain); and on the larch, pear, &c., is very exceptional. Its range of distribution is Europe and W. Asia, and in Britain is only prevalent in the S. half of England; it is not a native of Scotland or Ireland, but is there propagated as a curiosity. To the ancient Britons it was a special object of veneration, many important Druid rites being performed in connection with it, and a lingering record of this we perhaps see at the present day in the use of the plant for Christmas decorations. It was long extolled for its medicinal virtues, but these have unfortunately not survived to the present time. See Dr. Harley in *Trans. of Linnean Soc.*, vol. xxiv., and Dr. Bull in *Journal of Botany*, vol. ii.; also the writings of Edwin Lees of Worcester.

Mistral (a Provençal word, formerly *maestral*, Ital. *maestrale*, from Lat. *magistralis*, 'the masterful' wind), a N.W. wind that blows in winter over the western part of the Mediterranean, especially on the S. coast of France. It is dry and cold, sudden in its approach, and terrible in its effects both by land and sea. The M. is the *Caurus* or *Corus* of the Romans.

Mistretta, a town of Sicily, province of Messina, about 4 miles from the sea, and 18 miles E.S.E. of Cefalù. It has a brisk trade, especially in manna. Pop. (1874) 11,003.

Mitau, or **Jelga'va**, a town in Russia, government of Courland, in a sandy district on the An, 27 miles S.W. of Riga by rail. It has six churches, three synagogues, and the old castle and burial vault of the former dukes of Courland. M. manufactures japanned articles, and has considerable trade in corn, flax, and hemp. Pop. (1870) 22,185. The place takes its name from Mita, a Slavic deity.

Mite, a name given to members of the order *Acarina*, of the class *Arachnida* (q. v.). Of the acarina—which are small in size, have eight legs, a mouth fitted for biting, and a body usually covered with bristles—the common or domestic M. (*Acarus domesticus*) is a good example. The *A. destructor* is a terrible pest in museums, where it gnaws the fur of stuffed animals, and destroys the feathers of birds. The Sugar M. (*A. saccharinus*) inhabits sugar. The Itch M. causes the disease of that name. Many species are parasitic on beetles and other insects, and thus aid in preserving the balance of power in nature, by preventing the increase of these insects. The name M. is often erroneously extended to certain true insects, such as those belonging to the order *Mallophaga*, which infest the plumage of birds.

Mitford, John, an elegant English scholar, was born at Richmond, Surrey, 13th August 1781. After leaving Oriel College, Oxford, he obtained the living of Benhall, Suffolk, in 1810. In 1815 he was presented to the rectory of Weston St. Peter's, and in 1817 to that of Stratford St. Andrew, also in Suffolk. M. edited the *Gentleman's Magazine* from 1834 to 1850, and with fine critical acumen and ripe scholarship annotated many of the English poets in the Aldine edition. He died at Benhall, 27th April 1856.

Mitford, Mary Russell, daughter of a dissolute physician, was born at Alresford, Hampshire, 16th December 1787. Before she was twenty she had published three volumes of verse, receiving for the same a severe word from the *Quarterly Review*. Her first and greatest success was *Our Village*, a series of papers contributed to the *Lady's Magazine*, published in five volumes between 1824-32. She likewise wrote *Atherion* (a novel, 1824), *Belford Regis*, *Stories of Country Life* (1850). Of her tragedies, the best are *Julian* (1823), *Foscari* (1826), *Rienci* (1828). She brought out in 1854 her dramatic works (2 vols.), which included

Otho of Wittelsbach, Inez di Castro, and Gaston de Blondeville. M. wrote simply and feelingly; but the secret of her fame rests much in the private friendships she formed with many distinguished literary men and women of her day. Her filial generosity to a reckless and reprobate parent reveals a quality of character finer than anything she has written. In 1852 she published *Recollections of a Literary Life; or Books, Places, and People.* She died at Swallowfield Cottage, near Reading, January 10, 1855. M.'s letters were patched up into a *Life* by L'Estrange (Lond. Bentley, 1869); and Henry Chorley edited a second series in 1872.

Mitford, William, was born at London, 10th February 1744. He left Queen's College, Oxford, without a degree, and read law in the Middle Temple; but the death of his father in 1761 gave him ample means and leisure for study. In 1769 he became captain in the South Hampshire militia, of which Gibbon was major, and it is supposed that intercourse with this historian determined M. in his choice of literary work. After publishing in 1774 an *Inquiry into the Principles of Harmony in Language, and of the Mechanism of Verse, Modern and Ancient*, and *A Treatise on the Military Force*, he began to write his once famous *History of Greece*, vol. i. of which appeared in 1784, vol. ii. in 1790, vol. iii. in 1797, vol. iv. in 1808, and vol. v. in 1818. Though now entirely superseded by the works of Thirlwall, Grote, &c., it will always be remembered as one of the first genuine attempts at a Greek history founded upon original research, and enlivened by a pungent and vivid criticism. M. sat in Parliament from 1785 to 1815, and the political partisan is audible in his shrill structures on Athenian democracy. M. likewise wrote *Observations on Christianity*, and *Principles of Design in Architecture*. He died on the 8th February 1827. His brother, Lord Redesdale, prefixed a biographical notice to the 1829 edition of the History.

Mithras was the sun-god of the Persians, called the Invincible. He is commonly represented as a youth kneeling on a bull, whose throat he is cutting, and which is at the same time attacked by a dog, a serpent, and a scorpion, while a flying arrow is directed against the breast of the animal. These are astronomical symbols regarding the sun in Taurus, in which sign the vernal equinox occurred in ancient times. See Hyde's *Veterum Persarum et Medorum Religionis Historia*.

Mithridates, or Mithradates ('sun-given,' from Pers. *mithra*, 'the sun,' and the root *da*, 'give'), a name borne by several kings of Armenia, Commagene, Media, Parthia, Pergamus, and Pontus, of whom the most famous was **M. VI.**, King of Pontus, surnamed **Eupator** and **Dionysus**, commonly called **The Great**. Succeeding his father, **M. V.**, about 120 B.C., while under 13 years of age, M. began a career of unscrupulous ambition with the murder of his mother and brother. In a short time he subdued Colchis, Lesser Armenia, and the Tauric Chersonese, and, on the death of Parisades, he acquired the kingdom of Bosp. u.s. Nicomedes, king of Bithynia, having invaded Pontus, M. drove him (88) from Bithynia and Ariobarzanes from Cappadocia, seized Phrygia, Galatia, and Roman Asia, and caused the massacre of 80,000 Roman citizens. He also sent armies into Europe to help the Greeks in their rebellion, but in 86 Sulla twice defeated M.'s general Archelaus, near Charonea and Orchomenos in Beotia, and at the same time M. was himself overpowered in Asia by Fimbria. This, the *First Mithridatic War*, ended (84) with M. consenting to pay 2000 talents, and yield 70 ships to the Romans. In 83 Murena attacked M., but was defeated at the river Halys (82), and retreated, closing the *Second Mithridatic War*. In 74 M. began the *Third Mithridatic War* by taking the field with 120,000 foot and 16,000 horse, besides barbarian auxiliaries. He overran Bithynia, worsted the consul Coita at Chalcedon, and besieged Cyzicus, but the other consul, Lucullus, forced him to retreat (73) with great loss to Pontus, whence, after a severe reverse in 72, he fled to his son-in-law Tigranes, King of Armenia. Lucullus defeated both kings near Tigranocerta in 69, and near Artaxata in 68. Disaffection among his soldiers now obliged Lucullus to retire, and before the end of 67 M. had regained the greater part of Pontus. In 66, however, he was so hard pressed by Pompeius that he was forced to take refuge in the Cimmerian Bosphorus, where he established himself at the capital, Panticapæum, and resolved to pass round the Fuxine, through the Sarmatæ and Getæ, to invade Italy itself. But his

army mutinied, and made his son Pharnaces king, and in despair M. committed suicide (63). He was buried with royal honours by Pompeius at Sinope, his native town. This ambitious despot, Cicero confesses, was the greatest opponent the Roman arms had yet met. He had great skill in war, and extraordinary vigour of both mind and body; he could speak twenty-five languages or dialects, and his Greek education at Sinope had taught him to be a patron of the arts. For a graphic picture of his career and character, see Mommsen's *Römische Geschichte* (Eng. trans. vol. iii. Lond. 1863).

Mitrailleuse, a gun composed of several barrels, from which a number of shots may be fired simultaneously or in rapid succession. As early as the 14th c. such forms of ordnance were constructed; but experience proved the single-barrelled gun to be more effective. In the Franco-Prussian war, however, the French introduced an improved form, a small cannon revolver, capable of firing from 300 to 400 shots in a minute. The Gatling gun (see GATLING), first tried in 1862, is of the same nature, and has been adopted by the United States' army, and by several European powers. An English M. containing 50 cartridges was approved after trial at Woolwich, 18th January 1872.

Mitre (Lat. *mitra*) is the official head-dress in the Western Church of bishops, archbishops, some abbots and provosts, and, in a particular form, of the Pope. A kind of linen turban was the distinctive head-dress of the Jewish priests, and, with a gold plate in front, of the high priest. Now in the East a crown of this nature was the symbol of power and authority. The crown worn by the kings of Assyria was a high M., formed of bands of linen or silk. The head-dress of the kings of Egypt on state occasions was a *double M.* of the same kind. And a kind of regal power was vested in the Jewish high priest, who was the supreme head of the state, in fact the viceroy of Jehovah (*cf.* Deut. xvii. 12; Josh. xiv. 1, xvii. 4). It was this turban or holy crown of the Jewish high priest (*cf.* Ex. xxviii. 36) which was adopted by the bishop of Rome, and by him granted to other bishops. The horns of the M. are supposed to represent the cloven tongues of Pentecost (Acts ii. 3). More probably they represent a twofold power, as the double crown of the Egyptian kings represented the sovereignty of Upper and Lower Egypt. On the same principle the Papal tiara has been formed by the addition of three crowns to the common M., indicating three accessions of power: the first added by Pope Alexander III., 1159, the second by Boniface VIII., 1303, and the third by Urban V., 1362.

Mitre, in Architecture, is the line of junction of mouldings or other surfaces which meet at an angle.

Mitscherlich, Eilhard, a celebrated German chemist, was born at Neuende, near Jever, 7th January 1794, studied at Heidelberg, Paris, and Göttingen, went to Berlin in 1818, and threw himself eagerly into the study of chemistry. His discovery of the law of Isomorphism procured him the acquaintance of Berzelius, who invited him to Stockholm, where he remained from 1819 to 1821, when he was appointed Professor at Berlin on the death of Klaproth. Here he continued to labour till his death, 28th August 1863. His discoveries of Isomorphism and Dimorphism are what will permanently preserve his name; but his memoirs on Benzene and the Formation of Ether are also of the greatest value. M.'s chief work is his *Lehrbuch der Chemie* (1829-41). See Rose's *Gedächtnissrede* (Berl. 1864).

Mittimus is, in English law, a writ for transferring a record from one court to another.

Mittweida, an industrial town in the kingdom of Saxony, near the Zschopau, 35 miles S. E. of Leipsic by rail. It has large engineering works, cotton mills, dye-works, bleach-fields, and a trade in peat and building stones. Pop. (1875) 9093.

Mitylene. See LESBOS.

Mixed Marriages. The question whether in a marriage between two relatives who are both perfectly healthy, live under healthy conditions, and whose families are perfectly healthy, the children born will probably be unhealthy, is one little discussed, but of vital importance to society. Such marriages have been alleged to produce sterility, malformations, insanity, and special diseases of the senses, scrofula, albinism, phthisis, and cretinism. But in 1871 the House of Commons refused to make this the subject of inquiry in the census. The modern prohibitions

of marriage have descended from earlier social institutions, strengthened by Christian asceticism. But in ancient Egypt, Persia, and Arabia, there was little if any restriction on what is now called incest; and even among the Jews, Greeks, and Romans, marriages of very near kin were common, especially in the earlier and less corrupt times. The matured civil law permitted marriages in the fourth degree, or between first cousins: the canon law only outside the fourth or seventh degree, that is, third cousins are forbidden to marry. Hence the singular prejudice in England that, though first cousins may marry, second cousins may not. It would appear from the minute prohibitions in *Liber Pœn. de Incest*, in Thorpe's *Early Institutions*, that there was little restriction among the Old English. In fact, there does not seem to be any innate horror of marriage between near kin implanted in mankind. In savage nations we find the conflicting customs of exogamy and endogamy: the one probably based on the scarcity of women caused by female infanticide, or on the traditional honour of capturing a wife, and constantly supported by inter-tribal hostilities: the other on pride of race, which disdains alliance with foreign and therefore inferior women. Where these institutions have passed away, they still survive in the practice of many savage tribes in prohibiting marriage between certain relatives, and of others preferring marriage between near kin. But while exogamy may account for prohibitions of marriage between relatives of the third degree and beyond it, it hardly accounts for prohibitions among direct ascendants and descendants which occur in endogamous tribes, and have become part of the general law in modern times. These prohibitions are most universal where the parties are in the course of nature of an unsuitable age: against whose union, therefore, many obvious objections, not connected with kinship, may be urged; and they are not so strong in the case where the younger of the couple is a female, because females have less control over their marriages than males. It is certainly not true that intermarriage of kinsfolk has ever been prohibited on the ground that its effects on the off-spring have been observed to be injurious. No such effects have been observed. In those isolated communities, which have continually intermarried among themselves, such as the Cagots, the Vaqueros, the Chuctas, &c., no special rates of mortality, and no special percentage of disease, have been observed. The statistics collected by the Parasyngeneists are open to the fatal objection that there are no means of estimating the proportion of consanguineous to non-consanguineous marriages. Wherever such statistics have been collected with approximate safety, they suggest conclusions rather in favour of in-and-in breeding. The diseases attributed to consanguineous marriage are in truth the result of inheritance, which, of course, operates with increased power in producing disease or accumulating idiosyncrasy when organisations having similar faults are brought together. On the other hand, while judicious selection in crossing may remove inherited disease, the general tendency of crossing is to produce mediocrity, or reversion to an unimproved type—e.g., Anglo-Indian, Dutch Singhaies, Portuguese-Malays, the various half-breeds of America, &c. If a cross is *per se* beneficial, the more distant the relation the more beneficial ought to be the cross. But the generality of half-breeds are worse than their parent, and incapable of continuous reproduction. 'God made white men, and also black men, but the devil made half-castes'—(Livingstone, *Zambesi*, 50). It is very desirable that the efforts of Lubbock in England, Uytterhoeven in Belgium, and Mantregazza in Italy, may at last secure some authoritative public inquiry into this grave social question.

Mixtures are officinal, medicinal preparations, used as vehicles for more active medicines, or for their own intrinsic value. The following are the M. of the British Pharmacopœia with their doses:—M. ammoniaci, $\frac{1}{2}$ to 1 oz.; M. amygdalæ, M. creasoti, M. cretæ, M. ferri aromatica, M. ferri composita, 1 to 2 oz.; M. gentiane, $\frac{1}{2}$ to 1 oz.; M. guaiaci, M. scammonii, $\frac{1}{2}$ to 2 oz.; M. sennæ composita, 1 to 1½ oz.; M. spiritus vini Gallici, 1 to 2 oz.

Mizz'en, or Miz'en (Fr. *misaine*, 'foresail,' Ital. *mezzana*, 'lateen sail,' from *mezzano*, Lat. *medius*, 'middle'), a large triangular sail formerly attached to the stern-most mast of a three-master, so named from its running fore and aft, and thus keeping the *middle* line of the ship. M. is the name now given to the *mast*.

Mnemonics (Gr.), the art of refreshing the Memory (q. v.) by artificial aids, as by tying a knot in one's pocket-handkerchief; by associating the heads of a discourse with the various parts of a building, a system ascribed by Cicero and Quintilian to the Greek poet Simonides (500 B.C.); or by the substitution for figures of letters which may be formed into articulate sounds. Thus *a*, the first vowel, and *b*, the first consonant, may stand for 1, and *e* and *c* for 2, when *ac* or *be*, *eb* or *ca*, will respectively stand for 12 and 21. Of this last method, introduced in the 14th c., various modifications and improved systems have from time to time appeared, the best known being those by Richard Grey (1730), Gregor von Famaigle (1812), Aimé Paris (1833), and Karl Otto (1840). See Hermann Kothe, *Lehrbuch der Mnemonik* (Hamb. 1852); Stokes, *On Memory* (51st ed. Lond. 1875); and T. A. Sayer, *Aids to Memory* (Lond. 1875).

Mnemosyne (Gr. 'memory'), daughter of Uranus, the mother by Zeus of the nine Muses.

Mo'a, the name given by the Maories to a gigantic struthious bird belonging to the genus *Dinornis*, whose remains are abundantly found in New Zealand. Its existence was first ascertained by the Rev. Richard Taylor in 1839. In the article *DINORNIS* the M. is said to be wholly extinct, but in the *Greyhound Weekly Argus*, a New Zealand paper, there appeared a letter in 1876, signed R. K. M. Smythe, Browning's Pass, Otago, describing the capture of two living moas, 'a female 8 feet high, and a young one 3 feet shorter.' See *Chamber's Journal* (September 1877).

Mo'ab was the name of a Semitic tribe which occupied the highlands to the E. of the Dead Sea and the mouth of the Jordan (mod. Arab. *Belka* and *Kerak*). M. was a powerful nation when the Israelites arrived on the borders of Canaan, and escaping the disasters which overtook the latter, was still a 'very great nation' in the time of Josephus. The extraordinary number of ruins discovered in the country by travellers are a sure indication of the former wealth of the nation. See *The Land of M.*, by Dr. H. B. Tristram (Lond. 1873).

Mo'abite Stone is a remarkable inscribed stone which was discovered (August 19, 1868) by Mr. Klein, an English clergyman, near the ruins of Dibon (anc. Dibon), in the ancient land of Moab (q. v.). According to the best authorities it is 'the very oldest Semitic lapidary record of importance as yet discovered.' Unfortunately, although in 'a perfect state of preservation' when shown to Mr. Klein in 1868, it was afterwards broken to pieces by the Arabs, whose jealousy was aroused by the negotiations of European scholars to get hold of it, and only very fragmentary and imperfect copies of the inscription have been obtained. But even from what has been preserved 'the gain to paleography and Semitic science is enormous.' It also illustrates in a high degree the history of our own writing, exhibiting nearly the whole of the Greek alphabet in the identical Phœnician shape. This remarkable stone is 'the monument of a Moabite king, Mesha (cf. 2 Kings iii.), who, after a brief record of himself and his father, tells of certain deeds of war from which he issued victorious. Further, the names of Israel, Omri, Chamos, and a number of well-known Moabite cities occur up and down.' M. Ganneau has 'restored' the stone, filling up the lacunæ in the inscription to the best of his ability, and the Palestine Exploration Society has published a photograph of it from a cast presented by the Louvre authorities. See Ginsburg's *M. S.* (1871); Tristram's *Land of Moab* (1873); *Underground Jerusalem*, by Captain Warren (Lond. 1877).

Moat (? Fr. *molte*, Ital. *mote*, 'a mud or turf hillock') is the name now given to a wet or dry ditch drawn round the ramparts of a fortress, at least 12 feet deep and twice as many wide. When reveted with masonry, the interior slope of the M., nearest the parapet, is called the *scarp*, the exterior slope the *counterscarp*.

Mobile, a thriving city and port of entry in Alabama, U.S., on the river M., near its entrance into M. Bay, 30 miles above the Gulf of Mexico, and 140 E. of New Orleans by rail. It is situated on a sandy plain, girt by several beautiful hills, and has a fine climate, though subject to occasional ravages of yellow fever. Its harbour is shallow, but is being dredged (1877) at the cost of Congress, so as to secure a passage for vessels drawing 13 feet. Meantime large vessels have to remain 25 miles off in the bay. There is a large export trade in cotton, naval stores, lumber, rosin, and turpentine, and the staple import is coffee. On an average 50 vessels enter yearly from foreign ports

and 130 from American ports. M. has many handsome buildings, a city hospital, the Alabama Medical College, 30 churches, 2 daily and several weekly newspapers, &c. Pop. (1870) 32,034. M. was settled by Lémoyne de Bienville in 1702, and was the capital of Louisiana till 1723.—**M. Bay**, an inlet of the Gulf of Mexico, is 30 miles long from N. to S., and 10 miles broad, and is protected by Forts Morgan and Gaines, the latter standing on Dauphin Island at the entrance. The depth is about 12 feet, but near the outlet it increases to 21, and here the 'cotton fleet' is loaded by lighters from M. with the rich produce of Alabama. The M. river is one of the branches by which the Alabama river enters the bay.

Mobilier, Crédit, a French bank, originated in November 1852, for the purpose of lending money upon the security afforded by movable property. By its original charter the bank was permitted the privilege of paying up the calls made upon it by companies in which its money was invested, in its own notes or obligations. But when they proposed, after declaring a dividend of 40 per cent. in 1855, to make a paper issue of 240,000,000 francs, the public alarm compelled government to interfere. Many of the transactions of the C. M. have been upon the most enormous scale, and the industries of France owe to it much of their rapid development, as its funds flow largely into railway and other public schemes. Within recent years, however, its dividends have been on the decline, and the shares, which are 500 francs, were quoted on the Paris Bourse (October 3, 1877) at 155 francs.

Mobilisation, the placing of an army on a war footing, consists in filling up the field troops to their full strength, and in the formation of dépôt and garrison troops, as well as in the preparation for instant service of transport and commissariat supplies. See **ARMIES**.

Moch'a, a town in S.W. Arabia, province of Yemen, in a desert tract on the Red Sea, 80 miles W.N.W. of Aden. It has a good and well-fortified harbour. M. exports annually over 10,000 tons of the finest coffee, besides dates, gum, &c. Pop. about 7000.

Mocha Stone, a white translucent variety of agate exhibiting dendritic filaments, or moss like markings of a dark colour, produced by the infiltration of oxide of iron or manganese. It is found at Cambay, in India, and in Arabia, Mocha being the place to which the stones were conveyed for the purposes of trade, whence the name. It also exists in Wicklow. The *dendrachates* of Pliny and M. S. are identical.

Mocking-Bird (*Mimus polyglottus*), a species of *Merulidae* or *Thrushes*, found in N. America. The fourth and fifth quills are the longest; the bill has short bristles at the base, and the nostrils are oval. The tarsi have broad scales in front. This bird is of a dull brown colour, the quills of the wings having white bases. The two central tail-feathers are blackish, and the under parts are brown tinged with grey. The male has the white colour of the wings and the back line of the body more plainly impressed than the female. The average length is 9 inches. The eggs number four or five, and are of a greenish-blue spotted with brown. The M. is wary and active,

and wages war against other birds who attempt to encroach on its domain; while the black snake of America—a determined enemy both to birds and their eggs—is jealously watched and repulsed. The M., however, has acquired its celebrity from its extensive powers of vocal imitation. Any and every sound which the bird hears it is apparently able to imitate, often in the most exact manner. The cries of animals, the notes of other birds, and even tunes whistled in its vicinity, are correctly repeated by it. The natural song of the M. is bold and clear, but the bird so frequently and fully introduces the note of other birds and imitations of sounds into its vocal efforts, that its own notes are rather difficult of determination. The M. may breed twice or thrice annually.

Mocking Bird.

Mode (mus.). The arrangement of the scale of the octave into major or minor keys is called the major or minor M. Formerly the term had reference to time. See also **GREGORIAN CHANT**.

Modelling, the art of constructing an object in clay either as a model to be executed in marble, or to be cast in plaster or other material. The fine plastic clay employed is kept uniformly moist, and is manipulated in great part with the fingers, assisted where necessary by tools of bone, wood, or metal, having curved ends. Suitable supports must be given as the work progresses. M. in wax is pursued by medallists, goldsmiths, and other decorative metal workers, who employ ivory tools for the purpose. M. is also of great importance in the preparation of moulds from which enrichments in plaster-of-Paris, &c., for internal decoration, are cast.

Modena, the capital of the province of M., N. Italy, situated in a fertile and healthy plain, 25 miles N.W. of Bologna, and between the Secchia and Panaro, with which rivers it is connected by canals. Intersected by the Via Emilia, the city is one of stately buildings, broad streets, and spacious arcades, girt by ramparts commanding beautiful views of the Apennines and Æmilian plains. Its *duomo*, begun in Romanesque style in 1099, and consecrated in 1184, has a superstructure of later date. The campanile (*La Ghirlandina*) 335 feet high, erected 1224-1319, is one of the finest in N. Italy. The Palazzo Reale, formerly Ducale, is a magnificent turreted building, begun in 1634, and now containing the Bibliotheca Estense, with 90,000 vols. and 3000 MSS.; a picture-gallery, including works of Titan, Correggio, Tintoretto, Salvator Rosa, &c.; a museum of 26,000 medals; the Este archives, &c. M. has in all some twenty-seven churches, besides many educational and benevolent institutions, and a fine theatre. Its university was suppressed in 1821, but it still has good schools of law, medicine, theology, &c. There is a slight industry in linens, woollens, silks, hats, leather, glass, and paper. Pop. (1874) 30,854. M., the ancient *Mutina*, was made a Roman colony in B.C. 183, and is spoken of by Cicero as a splendid city. It declined from the time of Constantine, and is called 'but the corpse of a city' by Ambrose in 387. After suffering from the struggles of the Guelphs and Ghibelines, it fell in 1288 to the Este family (q. v.), under whom it rose conspicuous in the 16th c. as a brilliant centre of art and literature. The title of duke was conferred by Friedrich III. in 1452, and M. remained almost continuously with the family till the expiry of the male line in 1801, after which it passed by female line to Austria. Insurrections in 1848 and 1851 were quelled with cruel severity, but finally in 1859 Francisco V., the last duke, was driven from his territories. M. was soon afterwards finally annexed by popular vote to the kingdom of Italy.

Modern'to, a musical term signifying that the time is to be taken at a moderate pace.

Mod'erator is the name given to the Chairman of the General Assembly of the Scotch churches.

Mo'dica, a town in Sicily, province of Syracuse, on the Scicli (anc. *Molychanus*), 42 miles S.W. of the town of Syracuse. It lies in a fertile valley, hemmed in by high rocks, and has a castle and several fine churches. Five miles N. is the Val d'Ispica, with curious old rock-dwellings. M. is the Mohak of the Saracens, and the *Motuka* or *Mutyca* of the Greeks and Romans.

Modill'ion, in Architecture, a horizontal bracket placed beneath the Corona (q. v.) of a cornice, and only differing from a Console (q. v.) in having its larger end placed backwards, and the smaller one in front.

Modulation, a change of key, is a very common and attractive feature in modern musical compositions. Without it the effect of a piece is apt to be wearisome. M. into the attendant or relative keys is termed natural M., into other keys extraneous M. For very brief modulations the term 'transition' is used.

Mod'ulus, a constant coefficient or multiplier used in various connections in mathematics—more especially, however, in the theory of Logarithms (q. v.).

Mo'dus. Lands in England may be exempt from tithe, or partially so, by custom or prescription, in which case a M., or compensation, is substituted at twopence an acre for the tithe of land.

Möen, a Danish island, separated by Ulvsund from Seeland on the N.W., and by Grönsund from Falster on the S.W. Area, 77 sq. miles; pop. (1870) 13,348. The surface is undulating, and the soil is fertile. The inhabitants are engaged chiefly in agriculture, fishing, and shipbuilding.—The chief town, Stege, on the W. coast, is very old. It still retains privileges received from Erik Glipping in the 13th c., was taken by the Swedes in 1659, and was the scene of a Swedish naval exploit, 25th May 1710, which resulted in the capture of thirteen Danish men-of-war. Pop. about 2000.

Mœris (mod. *Birket-el-Kerân*, 'the lake of the horn'), a lake of Central Egypt, in the province of Fayum (q. v.), is supplied with water from the Nile by the canal Bahr-Jusuf ('Joseph River'), and is 30 miles long and 6 broad. The fisheries, which were formerly of far more importance, now yield only about £100 a-year. We have a splendid, though perhaps not strictly accurate, account of the lake from Herodotus.

Mœsia was a Roman province, bounded on the N. by the Danube, on the S. by the mountains Haemus, Orhelus, and Scardus, on the E. by the Euxine, and on the W. by Mount Scardus and the rivers Drinus and Savus. It was divided by the river Ceburis into M. Superior in the W., and M. Inferior in the E. The original inhabitants were Thracians, but a large body of Gauls settled there, B.C. 277. M. was subjugated by the Romans in the time of Augustus, and as a frontier province was strongly fortified along the S. bank of the Danube. In 305 the Ostrogoths, afterwards called Mœso-Goths, settled in M., with the permission of the Romans, with whom, however, they soon quarrelled and fought. In the 6th c. Slavonians entered Upper M., and in the 7th Bulgarians entered Lower M., establishing themselves easily in lands that had been wasted by Goths, Huns, and Avars.

Mœso-Gothic, the language of those Goths (q. v.) who in the reign of Aurich (270-275 A.D.) established themselves in Dacia. The Bible of Ulfilas (q. v.) shows that the M.-G. belonged, through its phonetic structure, to the Low German class, but grammatically it is, with a few exceptions, far more primitive than the Old English of the *Beowulf* or the Old High German of Karl the Great. Especially in the plurals of the verbs is the greater fulness of its forms apparent, closely answering as they do to the Latin terminations *mus, tis, nt*. The exceptions, however, are equally important, for they prove the grammatical, and therefore historical, impossibility of deriving either Old English, or High German, or both, from M.-G. See Diefenbach, *Vergleichendes Wörterbuch der Gothischen Sprache* (2 vols. Frankf. 1851); and Grein, *Das Gotische Verbum in Sprachvergleichender Ansicht* (Kass. 1873).

Moffat ('the foot of the moss'), an inland watering-place of Scotland, in the N. of Dumfriesshire, is situated in the rich sheltered valleys of the Annan, 2 miles N. by E. of the station of Beattock on the Caledonian Railway. The springs are chalybeate and sulphurous, and attract a large number of visitors, for whose accommodation there are handsome hotels, baths, reading and assembly rooms, &c. The town is protected to the N. by the M. Hills, which rise in Hartfell to a height of 2650 feet. Pop. (1871) 1730.

Moffat, Rev. Robert, D.D. a veteran African missionary, was born in Inverkeithing in 1797, and was sent in 1816 to Namaqua-land on the Orange River. When on a visit home in 1840 he published *Missionary Labours and Scenes in Southern Africa*. He is also the author of a translation of the Bible into the Bechuana language (new ed. 1872). His daughter married David Livingstone, and he may be said to have paved the way for the achievements of that great missionary, at whose funeral at Westminster Abbey he was one of the principal mourners. In 1873 he was presented with a testimonial of £5800. In May 1877, at the General Assembly of the Free Church of Scotland, in a speech on Foreign Missions, which virtually summed up his life work, Dr. M. reported that there were now churches and missions scattered over the Bechuana or Bassuto country from the Zulus on the E. to the Damaras on the W., that in connection with them there were 40,000 communicants and 45,000 pupils, and that some £250,000 worth of British merchandise is introduced yearly into the country. Since then he has probably startled a portion of the religious world by the publication of a letter in which he strongly pronounces in favour

of the lawfulness of marriage with a deceased wife's sister. For an account of his labours, see *Rivers of Water in a Dry Place* (1863; new ed. 1876), and Miss A. Manning's *Heroes of the Desert* (1875).

Mofuss'il (*mufassal*, derived from an Arabic word meaning 'separate'), a term in universal use among Europeans in India, to express the country generally, the rural part of a district, 'the interior,' as opposed to the Sudder Station or civil headquarters. Even a villager, when absent from his cottage in the fields, is said to be in the M. In Bengal, it is specially used for the whole country exclusive of Calcutta, the traditional boundary being the Mahatla Ditch (q. v.).

Mogadore, or **Suirah**, the chief seaport of Morocco, on a promontory running into the Atlantic, opposite a strongly fortified island, 130 miles W.S.W. of the city of Morocco. It has a great overland trade with the Sudan. In 1876, its exports, chiefly almonds, esparto, olive-oil, orchella weed, and beeswax, amounted in value to £275,333, of which £153,157 went to Great Britain and £118,064 to France. The value of the imports (cotton, sugar, tea, &c.) was £246,686, as much as £214,527 worth coming from Great Britain. There entered the port in 1876, 66 vessels of 24,001 tons (British 39, of 15,302 tons), and cleared 67, of 25,544 tons (British 40, of 15,845 tons). Pop. about 120,000.

Moguer (Arab. 'caves'), a town in the province of Huelva, Spain, overlooking the Rio Tinto, 43 miles W.S.W. of Seville. From its port, Palos, at the mouth of the river, Columbus set out on his great voyage of discovery, 31 August 1492. Pop. 7332.

Mogul (Mu'ghal, a corruption of Mongol), the name which history has indelibly fixed upon the dynasty founded by Baber, which endured at Delhi from 1526 to 1857. Baber himself was a Tartar, being descended on the father's side from Timur; his mother only was a Mongol, connected with the tribe of Genghis Khan. The name M. attached itself to the family in India as well as in Europe; and early travellers have familiarised us with the title of 'the Great Mogul,' though the court appellation was always Badshah, the Persian for king. The M. dynasty, which in power and historic grandeur yields only to that of Rome, was continued through seventeen emperors, of whom the greatest was the brave and enlightened Akbar (q. v.), and the last who retained any real authority was the bigoted Aurungzebe (q. v.). The dynasty closes with Mohammed Behandur Shah, 'the king of Delhi,' who was tried, deposed, and banished for his participation in the Mutiny of 1857. His son still lives, an exile at Tangu in British Burma; but the traditional glory which surrounded the name has now departed even from the minds of the Indian Mohammedans, having been to a large extent transferred to the *raj* of the new Empire. In architecture alone have the Moguls left a worthy memorial; in other public works they were lacking, but their mosques and their tombs at Delhi, Agra, and Fettehpore-Sikri will never be surpassed. It is curious that their emperors, almost without exception, attained to an extreme old age, when not cut off by a violent fate. The term M. is now generally applied throughout India, with an additional perversion of its original meaning, to all Mohammedan foreigners who are not Afghan or Pathan blood. In this sense, which includes Turks and Persians, though not Arabs or Abyssinians, who are separately classified, the general census (1868-72) returns 219,755 Moguls in India, most numerous in the N.W. Provinces, the Punjab, and Oude. See *The Fall of the M. Empire*, by H. G. Keene (Lond. 1876); Howorth's *History of the Moguls from the Ninth to the Nineteenth Century* (Lond. 1876), and *The History of India as told by its own Historians*, by Sir H. Elliot, and Prof. John Dowson (Lond. 8 vols. 1867-77).

Mohacs, a market-town of Hungary, in the comitat of Baranya, on the right bank of the Danube, 32 miles E.S.E. of Fünfkirchen by rail. It has five churches, large cattle-markets, and an important trade. Pop. (1869) 12,140. Here Lajos II. was defeated and slain, with 22,000 of his followers, by Suleiman the Magnificent, 29th August 1526, a defeat that for 160 years transformed a great part of Hungary into a Turkish province; and here too the Turks were in their turn totally routed by Karl of Lothringen, 12th August 1687.

Mo'hair, the hair of the Angora goat, an animal formerly peculiar to Asia Minor, but now acclimatised in Australia, Cape

of Good Hope, and California. Though the principal supplies of M. are still drawn from Asia Minor, it is probable that the British dependencies will soon surpass that region in its production. The vilayets of Angora and Kastambol produce the finest quality of M., for which England is the only market. The quantities annually imported into Britain amount to over 5,000,000 lbs., and the price obtained averages 2s. 10d. per lb. M. is white, silky in lustre, and long in staple. It is spun by machinery at Bradford and Norwich, and is manufactured into camlets, plush, velvet, braidings, laces, trimmings, and, mixed with cotton or alpaca, into dress pieces.

Mohamm'ed ('the praised') is the name adopted by the prophet, either on the announcement of his mission, or perhaps at the time of the Flight. His original and proper name was Kothan. M. was born at Mecca in the year 571 A.D. His father, Abdallah, of the tribe of the Koreish, died before M. was born, and his mother when he was six years of age. His grandfather then adopted him, but he also died two years later, and the boy was left in charge of an uncle, Abu Talib, who, as long as he lived, seems to have acted like a father towards him. Though sickly, and subject to epilepsy, M. had to work for his living, which he did by tending flocks. In his twenty-fourth year he entered the service of a rich trading widow, named Khadija, to whom he was soon afterwards married, although she was fourteen years older than himself, and by whom he had two boys, who both died young, and four girls. (The tales of visits with his uncle to Southern Arabia and Syria, between the age of thirteen and twenty-four, his instruction in Christianity by a Nestorian monk, and his being accidentally chosen arbiter in a dispute about the replacing of the Black Stone in the Kaaba, are now thought by the best authorities to be extremely mythical.) His personal appearance, according to the most authentic traditions, was as follows:—He was of middle height, thin in body, but strong limbed, with broad shoulders, a wide chest, and a quick, elastic, but firm step. His head was large, with a long mass of dark, slightly curled hair. His face of a 'red and white' complexion, was oval-shaped, framed in a full beard, with great, black, restless eyes shaded by long heavy eyelashes, and surmounted by long arched eyebrows, a large slightly aquiline nose, and well-set teeth of dazzling whiteness. In dress, eating, and drinking, he was exceedingly temperate. Strong drinks he abhorred, but was passionately fond of perfumes. His constitution was extremely delicate, and he was nervously afraid of bodily pain. He was affectionate in disposition, and gifted with large powers of imagination, elevation of mind, delicacy and refinement of feeling.

When he was at least forty years of age, he went, according to a custom of his countrymen, to spend the Rajab, or month of peace, on Mount Hira, a huge barren rock near Mecca. Here, in a dark cave, M. spent his days and nights in *tahannuth* (Heb. *tehinuth*, prayers, devotions). And when he slept he dreamed 'resplendent as the rosy dawn.' One night—'the blessed night Al Kadar, which is better than a thousand months'—he awoke and heard a voice which thrice called to him 'Cry.' After the third call he asked, 'What shall I cry; and the voice answered 'Cry, in the name of thy Lord' (cf. Isa. xl. 6). These were the first words of the Koran, although, according to the present arrangement, they appear in the ninety-sixth chapter. After the voice had told him how the Lord had created man of congealed blood, and 'by the pen' had told him that which he knew not, M. awoke, feeling 'as if a book had been written in his heart.' In a state of great excitement he hastened home to his wife, and told her what had happened. Khadija soothed him as well as she could herself, expressing her belief that he would be the prophet of his people. She then went to their cousin Waraka, who was old and blind, but knew the Scriptures of the Jews and the Christians. When he heard the story he exclaimed '*Koddus, koddus!*' (Heb. *kadosh*, 'holy'). Verily, this is the *namus* (Gr. *nomos*, 'law,' in Arabic also the bearer of a secret message, hence the messenger of the law) which came to Moses. He will be the prophet of his people.' Greatly comforted by the faith of his wife, which she firmly maintained till her death, and of Waraka, M. now waited in awe and trembling for more revelations, but none came, and his spirits sank till he resolved to commit suicide. But when he approached a precipice on Mount Hira for that purpose, he was confronted by Gabriel or the Holy Ghost, crying, 'I am

Gabriel, and thou art Mohammed, God's messenger, fear not!' After this he gradually gained confidence in himself and his mission, and now revelations came one after another during a space of more than twenty years. His first converts were his wife Khadija, his freed slave Zaid, his little cousin Ali, ten years of age, and Abu Bekr, a wealthy merchant, and a man of calm, clear judgment, whose adherence to M. throughout is regarded on all hands as one of the highest guarantees of the Prophet's sincerity, who indeed is said to have done more for Mohammedanism than the Prophet himself. Most of his relations, and the Meccans generally, treated his mission at first with contempt, but when he spoke of their gods as idols they waxed furious, and his life was in danger. This treatment, however, instead of cowering him, was the very means of dispelling his doubts and fears; his courage rose, and he openly defied his enemies. M. himself was effectually protected by his uncle, Abu Talib, although he did not believe in his nephew's mission; but some of his defenceless followers suffered martyrdom, and some apostatised. In order to save them, M. advised them to flee to Abyssinia, which they did, and found protection from the king of that country, who refused to give them up to ambassadors who were sent after them from Mecca.

But meantime M. himself had recanted twice, and although he immediately repented, he was for a time low-spirited, nervous, and full of fear, owing to the hopeless, almost single-handed struggle which he had to maintain. He was greatly cheered, however, by the conversion of Hamza, the 'Lion of God,' and Omar, who had been one of his bitterest enemies, but who has been called the Paul of Islam. The whole family of M., the Hashimites, were now excommunicated by the rest of the tribe, but after three years this ban was taken off, and M. received at least toleration. When about fifty-one years of age he lost his wife Khadija, whose unflinching faith had been his great support, and his uncle and protector Abu Talib. The immediate consequence of the death of the latter was to transform his other uncle and his great enemy, Abu Lahab, into his legal guardian.

The pretensions of M. had become known through the pilgrims, to whom he had preached, to the people of Medina, then called Yathrib, a great many of whom were Jews. Through them the Arabs had been familiarised with the god of Abraham, and threatened with punishment for their unbelief in him, when the Messiah should appear. Thinking it possible that this prophet, who, though their own countryman, preached the god of Abraham (see MOHAMMEDANISM), might be the Messiah with whom the Jews threatened them, they secretly sent two deputations to M. at Mecca, and on his expounding his doctrine to the second, they swore allegiance to him. From the deputation he chose twelve men to be 'bishops,' and called the rest of the people of Medina 'aids.' When this transaction became known in Mecca the indignation was intense, and to avoid it the followers of M. fled to Medina to the number of 100 families. A price was set upon the prophet's head, and a number of noble youths banded themselves together to take his life, so that he and his faithful companion Abu Bekr at last fled also, reaching Yathrib (henceforth called Medinat-an-Nabi, the 'city of the prophet') in September 622. The Mohammedan Era or Hejrah dates from the first month of the first lunar year after this event, and from this time till his death M. is judge, lawgiver, and king. The Jews, who at the time of his coming to Medina had encouraged him and caused him to believe in his mission, in the belief that he was to convert all Arabia to Judaism, finding that their tool was becoming too powerful for them, turned round and tried to make him ridiculous, the result of which has been that the hatred of Mohammedans against Jews has always been greater than against any other infidels.

In the first year of the Hejrah M. proclaimed war against his enemies, especially the Koreish and certain Jewish tribes, and with 316 men he defeated 600 Meccans. Six years after, a peace was concluded, and a pilgrimage to Mecca was carried out. Desiring to spread the faith beyond Arabia, he sent messengers to Heraclius, the Byzantine emperor, to the governor of Egypt, to the king of Abyssinia, to Chosroës, king of Persia, and to Amra the Ghassanide. Amra put his messengers to death, in revenge for which M. proclaimed war, in which he was defeated. The Meccans upon this seized the opportunity to rise against him, but before they were prepared he was upon them with 10,000 men, took the city by storm, and was proclaimed chief and prophet. In the year 10 of the Hejrah he went on a

pilgrimage to Mecca with at least 40,000 Muslims, whom he exhorted and blessed on Mount Arafat. He had just planned a vast expedition against the Greeks when he felt the hand of death upon him. Whether or not he intended to appoint a successor, as some think, he died without doing so, on the 11th or 12th of the third month of the eleventh year of the Hefrah (June 8, 632).

As to an estimate of the character of M., all that can be done here is to indicate the results arrived at by those who have studied the subject. He was introduced to Europe in 1529 by Luther, according to whom he was the 'Little Horn' of Daniel (viii. 9), and who wondered whether he or the Pope were the worst. According to Melancthon M. was inspired by Satan, and his sect was altogether made up of blasphemy, robbery, and shameful lusts. His first regular biographers—Prideaux, Spanheim, D'Herbelot, &c.—distinguished him by such epithets as 'wicked impostor,' 'dastardly liar,' 'devil incarnate,' 'Behemoth, Korah, Beast, 666 (cf. Rev. xiii. 18). But this grotesque vehemence of language gradually gave place to more civil names and more temperate representations both of the man and his doctrine; and the latest investigators 'have taught the world at large that Mohammedanism is a thing of vitality, fraught with a thousand fruitful germs; and that M., whatever view of his character be held, has earned a place in the golden book of humanity.' See Sprenger's *Mohammad* (Berl. 1861-65); Ameer Ali's *Mohamed* (Lond. 1873); E. Deutsch's *Lit. Remains* (Lond. 1874); Muir's *Mohomet* (2d ed. Lond. 1877); and Bosworth Smith's *M. and Mohammedanism* (Lond. 1874).

Mohammed is the name of several Turkish sultans, of whom the only notable one is **M. II.**, surnamed *Bujuk* ('the Great'). He was born at Adrianople in 1430, and succeeded his father Amurath in 1451. At the commencement of his reign he ravaged Greece, and built a fort which commanded the Bosphorus. He laid siege to Constantinople (April 6, 1453) with 250,000 men and 300 galleys. After the partial defeat of his fleet by the Genoese, he transported it by night overland into the harbour of Constantinople. The siege lasted fifty days; the city was carried by assault on May 29, and the Eastern Roman Empire came to an end. Mohammed attacked Belgrade in 1456, but was defeated by John Hunnyades with a loss of 20,000 men. He next subdued Trebizond, Lesbos, and Bosnia. He captured Belgrade in 1465, and conquered Albania in 1467. He took Negropont in 1470, defeated the Persians in 1472, and conquered the Crimea in 1475. Five years later he threatened Italy, and made an unsuccessful attack on Rhodes. He died at Nicomedia in May 1481. M.'s actions at different times reflected cruelty, magnanimity, perfidy, and generosity. Barbarous as many of his deeds were, he encouraged learning and civilisation, was himself an able linguist, speaking Greek, Arabic, and Persian, and understanding Latin; he was also a painter, and had a great knowledge of geography and mathematics. Several of his letters translated into Latin were published by Landini at Paris in 1520. While he did not scruple at any deed of violence necessary to satisfy his vast ambition, it does not appear that he loved bloodshed for its own sake, and on many an occasion he was tolerant and humane. To his lust for conquest the Turks owe the firm establishment of their empire in Europe. He was a great warrior and a sagacious statesman. See Knowles' *History of the Turks*, and Hammer's *Geschichte des Osmanischen Reichs* (10 vols. 1827-34).

Mohamm'edanism, the religion which was founded by Mohammed (q. v.), can only be understood in the light of the religious condition of Arabia at the time when he took up his mission. The religion of the country was composed of three different elements: certain forms of heathenism, chiefly nature-worship, Judaism, and Christianity. (1) Heathenism. Fetishism prevailed to a certain extent, as appears from certain sacred stones and trees—e.g., the Black Stone of the Kaaba, or temple ascribed to Abraham at Mecca, the White Stone at Taif, and various oracle-trees, one of which was near Mecca. Of a higher type was the worship of 'the host of heaven.' The Sun, the Moon, Jupiter, Venus, &c., had their temples, with their complement of priests. As a matter of course in such a stage of religious development, the people had their Lares (q. v.) and Penates (q. v.), sometimes of the rudest description; e.g., in one tribe the household god took the form of a piece of dough. Angels and demons also were treated with pious attention as

intercessors with the great Allah. (2) Christianity. The old theory that whatever is good in M. was derived from Christianity, has given way before recent investigation, for the Arabian Christianity of the time was of an incredibly low type. Mohammed's only instructors were certain Greek and Abyssinian slaves. The Syrian journeys, during which he is supposed to have become acquainted with it, are now considered to be mythical, as well as the monk Bahira-Sergius-Georgius-Nestor, by whom he is said to have been instructed. Thus, although the Christian doctrine of the sonship of Jesus Christ is understood in the Koran, it also combats the notion that Mary-Maryam 'the daughter of Imran, the sister of Hauran,' was the mother of God, and a member of the Trinity. It also contains some extraordinary stories from the Apocryphal (New Testament) writings, and the heretical notion that it was 'not Christ who was crucified,' but Judas; the hallucination being imposed on Christ as a punishment for his allowing people to call him God. (3) The most important of the three religious elements was that of Judaism. A number of Jews were found in Arabia at a very early period. Nebuchadnezzar caused more to seek refuge in the same country, and the Asmonæans caused a whole tribe of Arabs in the N. to adopt their religion. These Jewish tribes lived scattered all over Arabia, chiefly in the South, leading a pastoral or agricultural life, or they were congregated in cities: e.g., Yathrib (afterwards Medina), Kheibar (near Medina), and Yemen. Now the Jews were the cultivated class among the Arabs; they could all read and write, which few of the Arabs could do. The great accomplishment in Arabia at the time was poetry, and the Jews were especially gifted in this way. And not only were they superior in learning to their Arab countrymen, but they were familiar with the great Talmudic development of the Law which had been going on among their own brethren in Judæa and Babylonia; and great light is thrown by the Talmud on the teaching of the Koran, although the reverse of this has generally been supposed. In short they were called by the Arabs 'the people of the Book.'

As to the relation of M. to these antecedent faiths, Mohammed professed at the outset of his career to belong to the sect of the Hanifs (lit. 'hypocrites'), whose religion was a phase of Jewish-Christianity, or Christian-Judaism, and who styled themselves 'Abrahamite Sabians.' They believed in one God, and were guided by the Law, the Gospel, and certain 'rolls of Abraham and Moses,' called *Ashmaat* or *Shamaata* (Talmud. *Shemaata*, 'legal traditions' or Halacah), which were collections of Midrash (q. v). In this sect there were a number of men who had become disgusted with the fetishism into which most of their countrymen had sunk. Once four of them met at the Kaaba, during the annual feast, and expressed to each other their secret opinion: 'Shall we encompass a stone which neither heareth nor seeth, neither helpeth nor hurteth? Let us seek a better faith.' And the faith they adopted was the 'Religion of Abraham,' the Hanifite Creed. It was this creed that Mohammed established; he succeeded where others failed. To understand M., then, it is necessary to inquire what this 'Religion of Abraham' was, which formed its foundation. The word used for it in the Koran is *Milla* (Heb. for Chald. *memra*, Gr. *logos*). This 'Word' which Abraham proclaimed, teaches, says the Talmud, 'the existence of one God, the Creator of the Universe, who rules this universe with mercy and loving-kindness. He alone, also, guides the destinies of men. Idolatry, even when combined with belief in him, is utterly to be abhorred; he alone is to be worshipped; in him alone trust is to be placed in adversity. He frees the persecuted and the oppressed. You must pray to him and serve him in love, and not murmur when he asks for your lives, or even for lives still dearer to you than your own.' Regarding duties to man, it teaches: 'Loving-kindness and mercy are the tokens of the faith of Abraham.' 'He who is not merciful is not of the children of Abraham.' 'What is the distinguishing quality of Abraham's descendants? Their compassion and their mercy.' And this mercy and loving-kindness is to be extended to every human being 'without reference to garment, birth, rank, creed, or nationality.' Abraham, when he died, left to his children four guardian angels—Justice, Mercy, Love, and Charity. These traits of the faith of Abraham, which are to be gathered from the Talmud, form the foundation of M., 'often in the very words, always in the sense of these Jewish traditions.' 'Abraham,' says the Koran, 'was neither a Jew nor a Christian, but he was pious and righteous, and he was no idolater.' Both in

the Talmud and the Koran the greatest stress is laid upon the unity of God, the absence of mediators, and the repudiation of any special, exclusive, privileged creed.

The fundamental position on which Mohammed built his religion was that 'from the beginning to the end of the world there has been, and for ever will be, but one true orthodox belief; consisting, as to matters of faith, in the acknowledging of the only true God, and the believing in and obeying such messengers or prophets as he should from time to time send to reveal his will to mankind; and, as to practice, in the observance of the immutable and eternal laws of right and wrong, together with such other precepts and ceremonies as God should think fit to order for the time being, according to the different dispensations in the different ages of the world.' To this religion he gave the name of *Islam*, the great characteristic of which is generally supposed to be fatalism, but the real meaning of which is contained in Mohammed's own words:—'We have spoken unto thee by revelation—follow the religion of Abraham.' According to Deutsch, 'as far as Mohammed and the Koran are concerned, Fatalism is an utter and absolute invention.' The name Muslim, the derivative of *Islam*, is contained and explained in the Talmud. It is the word used for 'just, righteous man,' in a paraphrase of Proverbs xxiv. 16; and the word signifies 'one who strives after righteousness with his own strength.' Notwithstanding, it cannot be denied that the popular understanding of their creed on the part of Muslims practically amounts to Fatalism. 'God is supreme; what he wills can only be known by what he brings to pass; and against his decrees as manifested in the progress of events it is idle to strive.'

The great peculiarity of M. lies in this that it is 'at once a religious creed and a political revelation. Church and State are so completely identified that the religious life is made subject to the supervision of the courts of law, and the constitution of society and the government is supposed to be the result of a series of divine enactments. In religion, therefore, all spiritual development is treated as a crime against society and punished accordingly. In civil and political life all efforts after reform or improvement are regarded as a rebellion against the revealed will of God and punished as infidelity.' In short, every Mohammedan state is a theocracy, and hence the first propagation of M. was practically commensurate with the extension of the Saracen Empire. Mohammedan law consists of three elements, the Koran, the traditions, and the systems of jurisprudence taught by the four orthodox Imams. These, according to Muslim ideas, contain an accumulation of first principles which are above the reach of human criticism for two reasons: because they are an expression of the will of God, and because they are written in a language which is no longer perfectly understood. The Koran (q. v.) was set forth by Mohammed as a literal transcript of the ordinances written on the vast table which is before the throne of God for that purpose. These ordinances had often been revealed before to certain individuals selected from the race, but in the lapse of time these earlier revelations had become so corrupted that they rather deluded men than instructed them in the way of salvation. The Koran, as a perfect revelation of the will of God, superseded them all. The prophet had at all times, through the angel Gabriel, access to the 'preserved table,' so that in all his teaching it was not he that spoke, but the very Word of God. Further, in all his religious acts he was a divinely-revealed type and exemplar for the exact imitation of all his followers. The traditions, then, are the declarations of Mohammed regarding religious questions—moral, ceremonial, or theological, and records of all that he said or did, orally handed down by Ayesha, his favourite wife, the four 'rightly directed' califs—Abu Bekr, Omar, Othman, and Ali—and the six companions called the Evangelists of Islam. These transmitted their knowledge to their disciples; these to the next generation, and so on. Millions of anecdotes regarding the prophet, the greater number of which had originated in mere gossip or been fabricated by story-tellers, were soon floating about among the faithful, and in order to preserve whatever was authentic or valuable in them, collections were made, and certain tests applied to separate the true from the false. Thus Abu Daud Saleiman (A.D. 817–889) wrote down 500,000 traditions respecting the prophet, from which he selected 4800. Al Bokhari (810–870) made what is called the 'Authentic Collection,' having selected 7300 out of a mass of 600,000. But there are six collections which are received by all orthodox Muslims. Out

of the whole number of authentic traditions about 3000 refer directly to the prophet, and are partly historical and partly prophetic. The historical form an instructive commentary on the Koran, and are chiefly remarkable for the strange confusion of thought so apparent in the Koran, which placed on the same level serious moral offences, breaches of sumptuary regulations, and ceremonial omissions. The prophetic set forth especially the early Mohammedan beliefs regarding death, the resurrection of the dead, the last days, the final judgment, and the future life. As to the general body of the traditions they form 'a vast chaotic accumulation of legends about angels, demons, the origin of the world, and of all created beings.'

In their legal aspect the traditions were a collection of statutes supposed to embrace the entire sphere of man's daily life, so as to preclude the need for any appeal to the unassisted reason of man. The califs who succeeded Mohammed were merely the executors of a system already complete; but when a case arose for decision for which there was no precedent either in the Koran or the traditions, they had recourse to the method of 'analogical deduction.' This was the state of matters under the four 'rightly directed' califs, and after that analogical judgments were given by devout men who had learned by heart the Koran, the traditions, and the analogical judgments of the califs, especially seven divines known as 'the seven jurisconsults of Medina.' The first systematizer of this mass of unwritten learning, consisting of remembrances of the prophet, the teachings of the traditionists, and the judgments of the seven jurisconsults, was Malek Ibn Anas, the first of the four orthodox Imams (see MOHAMMEDAN SECTS), and a native of Medina. He dictated a treatise called 'The Beaten Path,' i.e., a system of jurisprudence embracing the entire sphere of human life, which speedily came to be regarded as of equal value with the Koran itself. The religion of Islam is divided into two parts: *Iman*, faith and theory, and *Din*, religion or practice. The one chief article of faith is that 'there is no god but the true God, and that Mohammed is his apostle.' But this is subdivided into six branches:—1. Belief in God; 2. in his angels; 3. in his Scriptures; 4. in his prophets; 5. in the resurrection of the dead and a day of judgment; and 6. in God's absolute decree and predetermination both of good and evil. There are four articles of practice:—1. Prayer; 2. alms; 3. fasting; and 4. the pilgrimage to Mecca. Nothing is more prominent in the Koran than the doctrine of the unity of God. The doctrine regarding the angels is borrowed from the Jews, who themselves had developed it under Persian influence. Besides angels and demons the Koran teaches the existence of another intermediate order of beings of a grosser fabric called Jin or Genii, some of whom are good and some bad. As to the Scriptures, the Koran teaches that God has given revelations of his will to his prophets at different times, to the number of 104. Of these 10 were given to Adam, 50 to Seth, 30 to Enoch, 10 to Abraham, and the other four—the Pentateuch, the Psalms, the Gospel, and the Koran—to Moses, David, Jesus, and Mohammed; but all are now lost except the last four. Of prophets whom God has sent into the world from time to time, all professors of the religion of Islam, there have been 124,000, or, according to another tradition, 224,000; of whom 313 were apostles sent with a special commission to reclaim mankind from infidelity and superstition; and six of them—Adam, Noah, Abraham, Moses, Jesus, and Mohammed—brought new laws and dispensations, which successively abrogated the preceding. As to a future state the Koran teaches that when corpses are laid in the grave they are examined by two angels as to their faith. If the answer be satisfactory, the corpse is permitted to rest in peace, if not, it is tormented till the resurrection. The body is entirely consumed except the bone called *ajb* (or *coccygis*), from which, as from a seed, the whole will be renewed at the Resurrection by a 40 days' rain: ideas the same as those of the Jews regarding the bone Luz and a dew. Hell is divided into seven apartments: the first for the reception of wicked Mohammedans, who after being punished there for a time will at length be released; the second for the Jews; the third for the Christians; the fourth for the star-worshippers; the fifth for the magicians; the sixth for the idolaters; the seventh for hypocrites, who profess some religion but in heart belong to none. The righteous as they enter Paradise drink from a *pond* which is supplied by one of the rivers of Paradise, after which they never thirst again. Thereafter follows a

mighty feast, and then each is dismissed to the mansion assigned to him. The comforts of these dwellings are regulated according to the merits of each, but the very meanest will have 80,000 servants and 72 wives of the girls of Paradise, who are of ravishing beauty, and called from their large black eyes *hural oyun* (Eng. *houris*), besides the wives he had in this world. The most delicious viands and wines will delight the palate without producing satiety, the most magnificent garments and furniture will please the eye, and the most ravishing music will fill the air. But it is to be understood that these sensual enjoyments are only the lowest, such as are common to all the inmates of Paradise. There is superabundant recompense of a spiritual nature promised to those of the highest degree. This exquisite delight, in comparison with which all the other pleasures of Paradise are forgotten, consists in the enjoyment of the favour of God, and beholding his face morning and evening. The doctrine of the Koran regarding predestination is that whatever hath or shall come to pass in the world, whether of good or evil, is irrevocably fixed by the divine will, and recorded from all eternity on the preserved table.

Of the four articles of religious practice the first is Prayer, which Mohammed used to call 'the pillar of religion' and the 'key to Paradise.' Five times a day, according to the express injunction of Mohammed, who received a revelation on the subject on the occasion of his *Miraj*, or journey to heaven, every true Mussulman engages in prayer, turning his face meanwhile towards Mecca. Almsgiving is of two kinds: legal, the amount of which is fixed by law, and voluntary. It is held to be highly meritorious, and of great efficacy in procuring answers to prayer. Fasting also is a religious duty of the greatest importance. It is expressly enjoined in the Koran that the whole month of Ramadan be observed as a fast from daybreak till sunset. Lastly, the pilgrimage to Mecca is so important that he who fails to perform it may as well die a Jew or a Christian. The chief ceremonies prescribed for the pilgrims consist in going in procession round the Kaaba, running between Mount Safa and Mount Morwa, performing their devotions on Mount Arafat, offering sacrifices, shaving their heads and cutting their nails. See Sale's *Koran*; Sprenger's *Koran, Mohammad, &c.* (Berl. 1861-5); Deutsch's *Lit. Remains; art. 'Islam'* (Lond. 1874); Bosworth Smith's *Mohammed and Mohammedanism* (Lond. 1874); Vambéry's *Islam im neunzehnten Jahrhundert* (Leip. 1875); and Muir's *Life of Mahomet* (new ed. Lond. 1877).

Mohammedan Sects. Mohammedans are divided into a great number of different sects—exactly 73, according to a traditional prophecy of Mohammed's—four of which are admitted to be orthodox, and all the rest heretical. The former get the general name of *Sunnites*, i.e., Traditionists, because they acknowledge the authority of the *Sonna* or collection of Traditions (see **MOHAMMEDANISM**), although, as we shall see, one of them—the Hanifites—do so only in a very small degree. Their founders are called the four orthodox Imams (see **IMAM**), and are regarded as the great authorities in jurisprudence. 1. The *Malekites*, who are most numerous in the N. of Africa, were founded by the Imam Malek Ibn Anas (A.D. 713-795), a native of Medina. His treatise, 'The Beaten Path,' which was a system of jurisprudence embracing the entire sphere of human life, and compiled from the Koran, the Traditions, and the judgments of 'the seven jurisconsults of Medina,' speedily came to be regarded as of equal value with the Koran itself. 2. The *Hanifites* were founded by the Imam Abu Hanifa-an-Noman (A.D. 699-767), a native of the Persian city of Basra, and the father of the legists known as 'the Jurists of Irak,' who differed from Malek chiefly in making almost no use of the Traditions as a source of law, admitting only 18 of them to be authentic. He professed to have drawn his jurisprudence entirely from the Koran, by 'analogical deduction.' Hence his followers have been called 'the followers of reason,' as distinguished from the other three Sunnite sects, or 'followers of tradition.' The Hanifite has been the most widely spread of the four orthodox systems. It was the one that prevailed at Bagdad during the time of the Abbasside dynasty, and is that which prevails in the Ottoman Empire at the present day. (3) The third sect, the *Shafites*, was founded by the Imam As-Shafi (A.D. 767-820), of the tribe of the Koreish, and the family of the Prophet, who followed the eclectic method of Malek rather than the deductive method of Abu Hanifa. He first

acquired a thorough knowledge of the systems of his two predecessors, and then built up his own of materials taken from both, but especially from the traditional precedents of Malek. The chief seat of his system was in Egypt, but Shafite doctors were rivals to those of the Hanifite school in all the principal cities of Asia. (4) The last of the four Imams was Ahmad-ibn-Hanbal (A.D. 780-857), a native of Bagdad and pupil of As-Shafi. His system, which never extended much beyond the precincts of Bagdad, and is now almost entirely obsolete, was a reaction against the rationalising tendency of the Hanifite system, according to the elastic method of which the court jurists, by skilful manipulation, got the doctrines of the Koran to permit the most iniquitous practices of califs and governors. To meet the wants of the society of his time, he conceived that a supplementary revelation was needed, and this he found in the mass of traditions which had accumulated since the days of Malek-ibn-Anas. From this he compiled a legal system, which was to render all appeal to human reason entirely superfluous.

Of the heretical sects there are also four principal ones, of which the rest are subdivisions. (1) The *Motazalites* ('Separatists') are the followers of Wasel-ibn-Ata, who was expelled from the school of Hasan of Basra for teaching that a believer who had committed a grievous sin was not to be deemed an infidel, but was in a middle position. Besides the above, his followers adopted the following tenets: (1) they rejected all eternal attributes of God; (2) they held that the Word of God consisted of letters and sound; (3) they denied absolute predestination, holding that God is the author of good only, and not of evil; and (4) they held that God could not be seen in Paradise with the bodily eye, and rejected all similitudes applied to God. (2) The *Safatians* ('Attributists') differed from the Motazalites chiefly in affirming the eternal attributes of God, this being the doctrine of the first Mohammedans. They afterwards introduced another species of attributes called declarative, expressed by speaking of God having, e.g., hands, eyes, &c., which, when understood literally, led to the notion of a likeness between God and man. (3) The name *Kharejites* ('rebels') was first applied to 12,000 men who revolted from Ali (A.H. 37), after the battle of Siffin, because he had referred a matter concerning the religion of God to the judgment of men, declaring him to be an infidel therefor. They also held that an Imam who turned aside from the truth might be deposed, and that any man might be raised to that dignity, although he did not belong to the tribe of the Koreish, provided he had the necessary qualifications. (4) The *Shiites* ('adherents') were the adherents of Ali-ibn-Abu-Taleb, in opposition to the Kharejites, maintaining that he was the lawful Calif and Imam, that the supreme authority, both temporal and spiritual, belonged to his descendants, and that the dignity of Imam is a fundamental affair of religion, not depending on the will of the people, but fixed by the prophet.

At the present day the chief antagonism to the Sunnites or orthodox Mohammedans is on the part of the Shiites. The controversy between them turns chiefly on the following points. The Shiites reject Abu Bekr, Omar, and Othman, the first three successors of Mohammed as usurpers, while the Sunnites regard them as rightful Califs and Imams. The Shiites regard Ali (the fourth) as the first true Imam, esteeming him, indeed, to be at least equal to Mohammed himself. The Shiites reject as unworthy of credit the *Sonna* or Collection of Traditions which the Sunnites receive as of canonical authority. And both charge each other with corrupting the Koran and neglecting its precepts; in short, they regard each other as abominable heretics, worse than Jews or Christians. Now as the Turks generally are Sunnites and the Persians Shiites, the greatest possible enmity exists between these two nations, although both are Mohammedan. See Sale's *Koran*; *Prelim. Diss.*; and R. D. Osborn, *Muhammadan Law*, in *Contemp. Review* (May 1877).

Mohammed Behaudur Shah, the seventeenth and last of the Mogul emperors of Delhi. He came to the throne, already in his old age, in 1837. He lent his name and influence to the Sepoy mutineers in 1857, and after the storm of Delhi by the British, he was captured alive by Captain Hodson in the mausoleum of Humayun. He was tried (January 27 to March 9, 1858), found guilty of murder, treason, and arson, and sentenced to transportation to Burmah. He subsequently died at Tungu, and there his youngest son, Jumma Bukht, still survives in exile. See Sir J. Kaye's *History of the Sepoy War* (vols. i.-iii.).

Mohawk River, the chief affluent of the Hudson, which it joins 10 miles above Albany, after an entire course of 140 miles. It flows in an easterly direction, through a beautiful and populous valley, once the chief abode of the *M. Indians*, a nation which belonged to the Iroquois family or confederacy. In 1784 this nation removed to Canada, where some hundreds still survive.

Mohicans or **Mohegans**, formerly a powerful tribe of North American Indians, belonging to the great Algonquin family, and occupying in the 17th c. the parts of the land now comprising the States of New York, Connecticut, and Massachusetts. Later on they were confined to Connecticut, and are now almost extinct.

Mohilev, or **Mogilev**, a government of Russia, bounded N. by Vitebsk, E. by Smolensk, S.E. by Tchernigov, and W. by Minsk. Area, 227 sq. miles; pop. (1870) 908,858 (103,000 Jews, 40,000 Poles). M. is drained by the Upper Dnieper, and its affluent the Zosh, and is one-third tilled land, one-fourth forest. —**M.**, on the right bank of the Dnieper, 92 miles S.W. of Smolensk, is the chief town. It has a cathedral, 21 other Greek churches, and 4 monasteries; is the seat of the Roman Catholic primate of Russia, and has 4 Catholic churches. There are one Lutheran church, and 22 synagogues. The manufacturing industries of M. are considerable, and much fruit is grown in the vicinity. There is a large transit trade with the Baltic and the Black Sea. Pop. (1870) 40,431. Another **M.** is in the government of Podolia, and is finely situated in a mountainous district on the Dniester, 195 miles N.W. of Odessa. It has extensive general trade with Moldavia and Wallachia. Pop. (1870) 18,129.

Möhler, Johann Adam, a Catholic theologian, born at Tübingen, in Wurtemberg, May 6, 1796, educated at Mergentheim and Ellwangen, studied at Tübingen and Rottenburg, and in 1819 was ordained priest. Returning to Tübingen, he was appointed a *privat docent* (1822), and Professor of Theology (1828); but, becoming embroiled in a bitter religious controversy with Baur and others of his colleagues, he was glad in 1835 to accept the chair of Biblical exegesis at Munich, where he died, April 12, 1838. Of his writings, in which he strove to harmonise the system of Schleiermacher with the teachings of the Church, the principal are *Die Einheit in der Kirche* (Tub. 1825), *Athanasius* (Mainz, 1827), *Symbolik* (Mainz, 1832), and *Neuen Untersuchungen der Lehrgesetze zwischen den Katholiken und Protestanten* (Mainz, 1834). His *Nachgelassenen Schriften* (2 vols. Ratisb. 1839-40) were edited by Dollinger, and his *Patrologie* (Ratisb. 1839) by Reithmayr.

Mohurbhunj ('peacock'), the largest of the tributary states of Orissa, India, in political connection with the government of Bengal, lies S. among the hills, E. of the district of Midnapore. Area, 4243 sq. miles; pop. (1872) 258,680; revenue, £20,515; tribute, £106. The products are honey, resin, lac, tussur silk cloth, timber, rice, and iron. The Rajah was of some importance at the beginning of the century, but much of his territory has lately passed under British administration. The capital is Baripada.

Mohurrum (*muharram*, derived from an Arabic word meaning 'sacred,' 'prohibited'; cf. the Latin *sacer*), the first month of the Mohammedan year, in which it was held unlawful to make war. The name is specially applied to the great fast or festival which is held during the first ten days of this month, in commemoration of the martyrdom of the grandsons of the Prophet, Hassan and Hussain. Dirges are recited of their sufferings, and tinsel models of their tombs are carried in crowded processions from the Imambara to the Karbala on the last day. This festival is only observed by the Shiah sect; and its celebration, which is attended with great pomp in all the large Mussulman towns of India, has always a tendency to result in a disturbance with the rival sect of Sunis.

Moi'dore, a now disused coin of Portugal, equal to 4000 reis, or about 27s. sterling.

Moines, Des, the capital and largest city of Iowa, U.S., on the Des Moines River, at the mouth of the Raccoon, 357 miles W. of Chicago by rail. It has been the State capital since 1855, and among its buildings are a U. S. court-house built of marble, an arsenal, twenty churches, &c. In 1876 a new State-house was being erected at a cost of \$3,000,000. The State library contains 20,000 vols. M. has three daily, seven weekly,

and three monthly newspapers, and in the vicinity there is extensive coal-mining. Pop. (1860) 3965; (1870) 12,035.

Moir, David Macbeth, a minor poet, was born January 5, 1798, at Musselburgh, near Edinburgh, and practised there as a surgeon. He early published *The Bombardment of Algiers*, and other poems, and became a contributor to *Blackwood's Magazine*, under the nom de plume of Delta (Δ). *The Legend of Genevieve* (1824), *Domestic Verses* (1843), and *The Autobiography of Mansie Waugh* (1828) first appeared in the magazine. The last of these is an admirable picture of the small, vulgar, shrewd, conceited, yet kindly Scot. It displays something of the racy humour of Galt with more tenderness and poetry, and constitutes M.'s best claim to remembrance. In 1851 he published *The Poetical Literature of the Past Half Century*, and *The Lament of Selim*. He died at Dumfries, July 6, 1851. Aird edited his works in one vol. (1857).

Moire is a term applied to watered silks. Stout silk of double width is only so figured, and the waved effect is produced by moistening the fabric, folding it carefully, so that the individual threads of the warp or woof lie directly over each other—the condition on which a successful result depends—and subjecting the whole to great pressure. The watered portions reflect the light, and are then displayed to advantage.

Moirée Metallique (Fr.), a name given to tinplate, exhibiting a beautiful crystalline appearance, produced by sponging over the metal a mixture of nitric and hydrochloric acids, then washing, drying, and lacquering. Boxes and other articles are made of it, but they are less common now than formerly.

Moissac, a town of France, department of Tarn-et-Garonne, on the right bank of the Tarn, 17 miles W.N.W. of Montauban. Pop. of commune (1872), 9036. There are the ruins of an ancient abbey with curious statues and carvings. M. has a trade in cereals and wines.

Mokudd'um (*mukaddam*, derived from an Arabic word meaning 'one who goes before, a leader'), a term introduced by the Mohammedans into India for the headman (*pradhan*, or *potail*) of the Hindu village community. In Orissa, where this name is especially in use, the M., from being merely a collector of the government revenue, has developed into a landlord with a proprietary interest in the soil. See Hunter's *Orissa* (Lond. 1872).

Mola, a seaport of Italy, in the province of Bari, on the Adriatic coast, and 12 miles S.E. of the city of Bari by rail. It lies amid gardens and olive groves, and has several fine churches. Pop. (1874) 11,775.

Molasse, the name given in Switzerland to the loose sandy deposits which occupy the central lake-region between the Alps and Jura, and which correspond in age to the Miocene (q. v.) formations. The contemporaneous conglomerate at the foot of the Alps is called *Nagelfluhe*. The shells are vegetable remains, and indicate freshwater agency for the most part, and a sub-tropical climate.

Molasses. See SUGAR.

Mold (Cymr. *Wyddgrug*), a parliamentary borough in the county of Flint, Wales, on the Alun, 11 miles W.S.W. of Chester, and connected with the rest of England by a branch of the Chester and Holyhead Railway. It is situated in a region rich in minerals, particularly coal and lead, and has in its vicinity many ancient British, Roman, and Old English remains, and the ruins of a fortress, and of a fortified hill. The county assizes and quarter sessions are held here. Pop. of borough (1871), 4534.

Mol'dau (Bohemian *Vltava*), the chief river in Bohemia, rises at the foot of the Vogelstein in the Böhmerwalde at a height of 3868 feet, flows S.E. to Hohenfurt (1736 feet), then turns N. towards Budweis, where it becomes navigable, and Prag, where it attains a breadth of 300 feet, and finally joins the Elbe at Melnik, after a course of 262 miles. It receives on the right the Masch, Luschnitz, and Sazawa, and on the left the Wotawa and Beraun.

Moldavia and **Walla'chia**. See RUMANIA.

Mole (*Talpa*), a typical genus of the family *Talpida*, which in turn is included in the *Insectivorous* order of *Mammalia*. The family *Talpida* is distinguished by its members having

a variable number of incisor teeth, the canine teeth being frequently absent, and their place taken by false molars. The molar teeth have sharp tubercles, adapted for crushing the insects on which these animals feed. The feet have five toes, and the animals are *plantigrade*, i.e., place the whole sole of the foot on the ground in walking. In the Moles themselves six upper and four lower incisors exist. The canines number two and the molars six in each jaw, the premolars numbering eight above and six below. The muzzle is long and blunt at the extremity; the eyes are small and concealed by the fur, and the tail is short. Five toes exist, the fore feet have the soles turned backwards, and the claws are strong. The common M. (*Talpa Europæa*) is one of the most familiar of quadrupeds. Its burrows or dwellings are of very definite shape and form. A central fortress is generally constructed, from which various tracks radiate to the feeding ground. The nest in which the female brings forth the young is also formed in an ingenious and careful fashion. The young, numbering from 4 to 7, are born in April, but may appear later in the summer. The colour of the M. is generally blackish grey, but some specimens have been found of white and cream colour. The M. is very pugnacious. Fierce combats take place between the males, and it is alleged that the victor not merely kills but eats the vanquished. The ordinary food consists of earthworms, which the M. captures with dexterity. The fore-limbs are mainly used in burrowing, and from the manner in which the palm of the hand is turned backwards, the work of scooping out the earth is readily performed. A special bone is developed for the support of the muzzle, and the collar-bones are strongly made. The golden M. (*Chrysochloris aureus*) is a S. African species, the hairs of whose fur shine with iridescent hues, and thus obtain for its name. The teeth of the golden M. interlock in a curious fashion. Its fore feet have four toes, and the hinder feet are five-toed, the nail of the middle finger being very large. The star-nosed M. (*Condylura* or *Astromyces cristatus*) is a N. American species, deriving its name from the peculiar star-shaped cartilaginous disc in which the nose terminates. About twenty horny 'caruncles' or rays form this peculiar structure, the nostrils opening in its centre. The colour resembles that of the common M. The shrew M. (*Scalops aquaticus*) is also a N. American species, and appears to be of aquatic habits. The length of its muzzle is about 16 inches.

Mol¹⁶, Matthieu, one of the most illustrious magistrates of France, belonging to an old parliamentary family, was born in 1584. While holding the office of procureur-général, Richelieu in 1641 appointed him First President of the Parliament of Paris. During the stormy period of the Fronde (q. v.), he defended with equal zeal the interests of the people and the rights of the crown, and in consequence had to struggle at times against both. In 1651 he was made Keeper of the Great Seal, and although his sense of justice was at times embarrassing to the Court and the nobles, it won for him a national respect which secured his position against assault. M. died 30th January 1656. See his *Mémoires* (3 vols. Par. 1854-56), edited by Champollion-Figeac. —**Edouard François Matthieu M.**, born 5th March 1760, became President of the Parliament of Paris in 1788. He married a daughter of Malesherbes, emigrated in 1789, and returned to France in 1794 to fall a victim to the guillotine on the 20th of April. —**Louis Matthieu, Comte de M.**, son of the preceding, was born at Paris, 27th January 1781, emigrated with his father on the outbreak of the Revolution, lived partly in Switzerland, partly in England, and at the age of sixteen returned to France, where he sought by hard study to make up for the neglected education of his youth. Through the influence of Mme. de Beaumont he entered into the society of Pasquier, Chateaubriand, and Joubert. In 1806 M. was brought under the notice of Napoleon through a review which called his attention to a volume—*Essais de Morale et de Politique*—published the year before. He was immediately chosen as one fitted for positions under government. In February 1806, he became Auditor of the Privy Council; in June *Maître des Requêtes*; in November 1807, Prefect of Côte d'Or; in February 1809, Councillor of State; in October, Director-General of Roads and Bridges, after which he was raised to the peerage and entered the Cabinet. Under Louis XVIII. he acted (1817) as Minister of Marine. In the first cabinet of Louis-Philippe M. (14th August 1830) was Foreign Minister, and (1836) he again took

the post, accepting (1837) the Premiership after the resignation of Guizot. Two years after he resigned, and (21st February 1840) was appointed a Member of the French Academy. On the 23d November 1855 he died at the Château de Champlâtreux. He had practically retired from affairs for fifteen years.

Mole-Cricket (*Gryllotalpa*), a genus of *Orthopterous* insects, burrowing in the ground by means of greatly developed fore-limbs. These limbs are short, stout, and flat, having strong spinous projections, especially in their terminal parts. The eggs, numbering from 300 to 400, are laid in tough capsules in subterranean galleries. The common M.-C. (*G. vulgaris*) is scattered over the greater part of Europe. It attains a length of 2 inches, and is of a brownish colour. The wings are short, and the fore-legs are used for cutting plant tissues, as well as for burrowing. Like its mammalian namesake, the mole, it is very combative. It also effects great destruction amongst plants. *G. longipennis* and another species (*G. didactyla*) commit ravages of great extent amongst the sugar-canes in the W. Indies. *G. borealis* is an American species inhabiting moist earth near ponds and rivers. The M.-C. has a peculiar chirp or call, made by movements of the wing-covers.

Mol¹⁶ecule (Fr. diminutive of Lat. *moles*, 'a mass'), is the smallest quantity of a substance which can exist in a free state. Molecules must not be confounded with atoms, which are defined as the ultimate indivisible particles composing matter. A M. may be divided, but it then ceases to be the same M. Molecules of the same substance are alike in mass, form, and constitution, but are different from those of other substances. Concerning the ultimate constitution of molecules we know nothing definite, but theory inclines to regard a M. as an aggregation of atoms, or even of other molecules. For instance, in chemistry, a M. of water is made up of a M. of hydrogen and half a M. of oxygen. Now, according to Avogadro's Law, deduced originally from experiment, but an immediate consequence from the kinetic theory of gases (see GASES), equal volumes of different gases at the same temperature and pressure contain the same number of molecules. Hence to form water, hydrogen and oxygen must be mixed in the proportion of two volumes of the former to one volume of the latter. The study of molecular physics is daily becoming more and more important; and it is in this direction that we naturally look for the next great advancement in science. The phenomena of light, sound, electricity, magnetism, &c., are now recognised as molecular phenomena; and anything which tends to make clearer our vision of the ultimate nature of matter must necessarily result in wider views of the transformations of these various forms of energy.

In natural history the *molecular theory* of organisation is a theory which assumes that the various tissues and parts of animals and plants originate from the aggregation of infinitesimally small particles of organic nature named 'molecules.' The late Professor J. Hughes Bennett of Edinburgh was one of the chief supporters of this idea, and described the formation of cells as resulting, in many cases at least, from aggregation of molecules. These molecules are believed to possess inherent vital properties, in virtue of which they grow and reproduce their like, and exhibit the movements described under the title of *molecular motion*—a process of movement, however, liable to be closely imitated by the motion of particles of inorganic substances in fluids.

Mole-Bat (*Spalax*), a genus of *Rodent* Mammalia, forming the type of a family (*Aspalacide*) having large and projecting incisor teeth, very small outer ears, and small and rudimentary eyes. The feet are short, and the claws small. The tail is short or absent. The Common M.-R. (*Spalax typhlus*) or 'sleeper,' inhabits S. Russia, Syria, and Asia Minor generally. It burrows, like the insectivorous mole, underground. Its food is of vegetable nature, and appears to consist largely of roots. The colour is a light brown, inclining to red. The average length is 10 inches. Nearly allied to the M.-R. is the Coast-Rat or Sand-Mole (*Bathyergus marinus*), found on the coasts of S. Africa. The teeth are exceedingly prominent, and the claws very long and powerful. The colour is a greyish brown, and the length about 15 inches.

Mole'skin, a stout heavy fabric of cotton woven like satin, and used principally for the trousers and other working garments of out-door labourers, and for the clothing of male inmates of workhouses, &c.

Molesworth, Rev. William Nassau, an English historian, born at Millbrook, near Southampton, 8th November 1816, was educated at King's School, Canterbury, at St. John's and Pembroke College, Cambridge, where he graduated in 1839, took orders in the Church of England, and was made vicar of St. Clement's Spotland, near Rochdale, in 1844. He has written a *History of the Reform Bill of 1832* (1864), *A New System of Moral Philosophy* (1867), and a *History of England from the Year 1830* (3 vols. 1871-73; new ed. 1874). The last in particular is an admirable record of one of the most instructive periods in the national history.

Molesworth, Sir William, an English philosophical politician, belonged to an old Cornish family, and was born in London, 23d May 1810. Educated at Edinburgh and in Germany, he entered the House of Commons in 1832 as an advanced Liberal, voting for national education, the ballot, and Jewish emancipation. From 1837 to 1841 he represented Leeds, and when Lord Durham's Canadian administration was under discussion he made some remarkable speeches on Colonial government, and attacked with crushing effect the system of transportation. Four years of leisure were devoted to study and to the fine edition of Hobbes' Works, which cost him £6000. In 1845, in spite of his support of the Maynooth Grant, he was returned for Southwark, which he represented till his death, 22d October 1855. M. understood and assisted the financial reforms of Peel, took office in the Public Works Department under the Aberdeen Ministry, and was made Colonial Secretary by Palmerston in 1855. He has been called 'the liberator and regenerator of our colonial empire;' and he was certainly a man of vast information on political subjects, of clear and exact thought, and of great administrative promise. M. was the owner, and for a time the editor, of the *Westminster Review*, and an intimate friend of John Stuart Mill and Grote.

Molfetta, a seaport of Italy, province of Bari, 61 miles S.W. of Foggia by rail, has a small harbour, formed by a mole and natural breakwater, and a fine cathedral, numerous churches, a castle, and a college. The linen manufacture is the principal industry, and there is a considerable trade in corn, oil, fruits, &c. In the neighbourhood are the celebrated Nitre Caverns—of them 1400 feet in circumference—which yield 500 tons of saltpetre annually. Pop. (1874) 26,516.

Molière, Jean Baptiste Poquelin (the name 'Poquelin' is spelled in half a dozen different ways), son of Jean Poquelin, originally a *tapissier*, subsequently valet-de-chambre to Louis XIII., with reversion of the office to his son, was born at Paris, 15th January 1622. Until his fourteenth year he attended at the shop, and learnt nothing; but through the influence of his grandfather he became attached to the drama, was sent to the *Collège de Clermont*, afterwards studied under Gassendi with much profit, and became an accomplished scholar and disciple of Epicurus. He accompanied the king in the capacity of valet-de-chambre to Languedoc in 1642, and on his return to Paris associated himself with a company of players who performed at the Faubourg Saint-Germain, assuming in 1646 the name of Molière. From 1646 to 1658 his movements were of the most irregular sort, but he has been traced with his company to the towns of Nantes, Lyon, Bordeaux, Narbonne, Pezenas, Grenoble, and Rouen. During these wanderings he had the patronage of the Prince de Conti, and wrote *L'Étourdi*, a comedy of intrigue, and the *Dépit Amoureux*, in which his bent towards the humorous interpretation of life and character began definitely to reveal itself. In 1658 M. and his troupe returned to Paris, played before Louis XIV. on the 24th October, in the farce *Docteur Amoureux*, which obtained a *succès de rire*. Liberty was given him to establish a company at the Petit-Bourbon Theatre, bearing the official name *La Troupe de Monsieur*. During the next fifteen years he wrote thirty comedies. His first triumph was achieved in *Les Précieuses Ridicules* (November 1659), which, while in form it resembled a farce, was penetrated by the most trenchant spirit of comedy, and made an end of the absurdities of the Hôtel Rambouillet. More and more he determined to study the actual world, and to lean less upon Terence, Plautus, and the Italian school. *Scapinelle* (1660) and *Don Garcia ou le Prince jaloux* (1661) reveal the growth of his insight in this direction, and *L'École des Maris* (1661) rises to the creation of more definite types of individual char-

acter than he had yet produced. It marks the height of his earliest manner. M. married in 1662 a girl of eighteen, Armande Béjart, his relationship with whom exercised a powerful influence over his feeling and thought, which was reproduced in more than one of his dramas. In the midst of much domestic happiness he produced (1662) *L'École des Femmes*, a pure comedy of manners, and the following year *L'Impromptu de Versailles*, which is full of satirical portraiture of contemporaries. A son was born to him 19th January 1664, to whom Louis XIV. acted as godfather. Besides the production of some lively farces, M. this year succeeded in getting a hearing for three acts of *L'Hypocrite*, which afterwards became the *Tartufo*, but was soon suppressed. Some of its dominant ideas were, however, allowed to get vent in *Don Juan ou le Festin de Pierre*, which appeared in 1665, much to the disgust of the clergy, whose uproar caused the elision of some important scenes. But the friendship of the king, who supported him amidst an abundant hostility of criticism, was now shown by a pension and the honorary title to M.'s company of *Troupe du Roi*. On the 15th September appeared his *L'Amour Médecin*, in which the faculty was overwhelmed with railery of the most brilliant and incisive sort, the result of observations made upon medical pomposity and inefficiency during an illness. On the 4th of June 1666 was acted *Le Misanthrope*, one of the brightest examples of comedy in existence. In it M. subjected intrigue to the natural development of characters, and, taking for the central motive of the piece the unhappiness of his own experience with a young wife surrounded by admirers, he played with his own moods of bitterness in the spirit of wise and healthful comedy. *Le Médecin malgré lui*, a bright vivacious satire, belongs to the same year. Not till the 5th of February 1669 was *Tartufo* allowed in its integrity to appear upon the Paris stage. It is the play by which M.'s name has become best known to the world, and has taken rank among the highest of his achievements. There is consummate art in the management of the principal figure, the priestly sensualist, who stands branded as the crown and flower of hypocrisy; there is admirable discrimination and variety among the surrounding characters, and an infinite range of emotional and intellectual expression. In 1668 appeared *L'Avare* and *Georges Dandin*, the former modelled on *Plautus*, but so enriched with additions of M.'s own that it has been called a *chef d'œuvre de l'imitation originale*. *Le Bourgeois Gentilhomme* (October 1669) reduced to an absurdity the prevalent passion for aping aristocratic ways; *Les Femmes Savantes* (March 1672) presented to the laughter of Paris, in scenes and language abounding with beauties, the absurdities of pedantry, and the farce *Le Malade Imaginaire* (1673) closed his career as a dramatist. He died at Paris, 17th February 1673, the Archbishop of Paris refusing him a Christian burial, but at the king's request the body was interred in the cemetery of St. Joseph. Like Shakespeare, M. found but mean traditions of comedy in the literature of his country, mere uproarious farce and buffoonery, which he raised into a high and enduring art. The immemorial puppets of previous writers he swept off the stage, and substituted living men and women, in whose attitudes and relationships he let the world mirthfully see itself. As with Shakespeare, too, it is his special glory, whilst catching and satirising the tendencies of his generation, to have stamped the hall-mark of humanity on his characters, so that they remain representative for all time. His genius has penetrated the language of France, and his wit and wisdom flow spontaneously as proverbs from the lips of all men. His joyful humour, his robust sense, his profound and inexhaustible knowledge of the human heart, and his detestation of cant, are among the qualities which entitle him to the first place in the literary history of his country. It would be impossible within our space to enumerate even the chief editions of M.'s *Œuvres*. We may note those of Barbin (7 vols. Par. 1674), of Bret (6 vols. Par. 1773), of Petitot (6 vols. Par. 1812), of Taschereau (8 vols. Par. 1823-24), of Moland (7 vols. Par. 1863-64), of Pauly (8 vols. Par. 1874), of Eugène Despois, which contains all the historic and literary documents relating to each play (Hachette, vols. i. and ii. 1873-75). The person responsible for most of the obscurities and errors which long shrouded and distorted the biography of M. is Grimarest, whose *Vie de M.* appeared in 1705; but within the present century the researches of loving scholars have done much to rectify the mischief. See Taschereau, *Histoire de la Vie et des Œuvres de M.* (1825); Bazin, *Notes*

Historiques sur la Vie de M. (1851); Soleirol, *M. et sa Troupe* (1858); Lacroix, *La Jeunesse de M.* (1858); Soulié, *Recherches sur M.* (1863); Fournier, *Le Roman de M.* (1863); Campardon, *Documents inédits sur J.-B. P. Molina, Luis, a Spanish Jesuit, born at Cuenca, New Castile, in 1535, studied at Coimbra in Portugal, and was appointed Professor of Divinity in the Portuguese university of Evora. In 1588 he published a book entitled *De Liberi Arbitrii Concordia cum Gratia Donis Divina Præscientia, Providentia, Prædestinatione, et Reprobatione* ('Harmony of Free Will with the Gifts of Grace, &c.'), in which he set forth opinions on the relation of Grace to Free Will, differing from the received doctrine of the Church, as expressed by Augustine, and expounded by Thomas Aquinas. The book was immediately attacked by the Dominicans (q. v.), who charged M. with Semi-Pelagianism, while the Jesuits, without at first adopting his opinions, denied that they were Pelagian or heretical at all. The controversy waxed so hot, that in 1594 the Pope (Clement VIII.) enjoined silence on both parties, and the dispute was referred to a committee of theologians which met in 1598. Their meetings, called 'Congregaciones de Auxilios,' were continued for three years, and then a decision adverse to M. was given in 1601, the year in which M. died.

Molinism is the name given to the doctrine taught by Molina (q. v.) regarding Grace and Free Will. At the third of the Congregaciones (de Auxilios) the opinions of M. were thus summarised:—1. A reason or ground of God's predestination is to be found in man's right use of his Free Will; 2. In order that the grace which God bestows on men may become the *gift* of perseverance, it is necessary that they be foreseen as consenting and co-operating with the divine assistance offered them, which is a thing within their power; 3. There is a mediate knowledge ('scientia media') by which God knows future contingent events before he forms his decree; 4. Predestination is either general, for which there is no ground on the part of the persons themselves beyond the mere good pleasure of God, or particular, for which there is a ground in the foreseen good use of Free Will. This 'scientia media' was afterwards adopted by Jesuit theologians, and the Dominican views in an extreme form were published in the *Augustinus* of Jansen (q. v.).

Molinos, Miguel de, a Spanish mystic of noble family, was born at Patencia, near Saragossa, 21st December 1627, and studied theology at Pamplona and Coimbra. After having received orders, he went to Rome, where he became a much-sought-after confessor. He published his *Guia Spirituale* in 1675, in which he insisted that perfect Christianity consisted in tranquillity of soul, the pure love of God apart from desire of recompense, the renouncing of the world, and the entire abstraction of thought and will from temporal things, and their concentration upon God. In 1683 he was arrested by the Inquisition, and in 1687 sixty-eight propositions of his books were declared contrary to the purity of the Church. He was then imprisoned till his death, December 29, 1690.

Moll'ah, a title given to certain Turkish officers whose functions are principally judicial, but partly ecclesiastical. The four mollahs who preside over the great pashaliks of Adrianople, Brusa, Damascus, and Cairo, are of the highest rank. The others who legislate in smaller districts are appointed monthly.

Mollusca (Lat. *molluscus*, 'soft,' from *mollis*), a sub-kingdom of animals, including those forms which, zoologically speaking, may be named 'shell-fish.' Thus mussels, limpets, and clam-shells are true M. In addition to the groups of true shell-fish, such animals as the sea-mats (*Polyzoa*), &c., sea-squirrels (*Tunicata*), and lamp-shells (*Brachiopoda*) are included in this sub-kingdom; and the cuttlefishes (*Cephalopoda*) and 'sea-butterflies' (*Pteropoda*) are also M., the former animals being the highest members of the group. The *Polyzoa*, *Tunicata*, and *Brachiopoda* are by most zoologists recognised as forming a lower assemblage of the M., to which the name of *Molluscoida* (q. v.) has been applied. The general characters which relate the large series of animals named 'molluscs' into one sub-kingdom, are found (1) in the general, but by no

means universal, presence of a *Shell* (q. v.). Many molluscs want a shell; e.g., the *Polyzoa* and *Tunicata*; but some molluscs included in shell-possessing groups may also be 'naked.' Thus the *Dorida* or 'sea-lemurs,' and the sea-hares, &c., among the *Gasteropods*, illustrate naked molluscs, classified with true shell-bearing forms; but it is notable that in their early or embryonic state of existence, such naked molluscs, along with all other higher M., possess a rudimentary shell. (2) A *perfect digestive system* is, save in a very few instances, apparent in all M. The recognition of this character serves to distinguish such lower M. as the *Polyzoa* from the *Zoophytes*, to which, in outward appearance, they present a close resemblance. The latter have at most an incomplete digestive tract. The digestive system lies in the median line of the body, while the heart, or centre of the *hamal system* lies dorsally in M., and the chief *nerve-centres* ventrally, or on the lower aspect of the body. (3) The character of the *nervous system* forms a distinctive feature in M. This system, in all higher M., consists of three *ganglia* or nerve-masses. These are connected together by nerve-cords, and are disposed, one in the head (*cerebral* or *cephalic ganglion*), one in the foot-region (*pedal*), and one in the neighbourhood of the heart and gills (*branchial* or *parieto-splanchnic*). This irregular disposition of the nervous system has suggested Owen's name of *Heterogangliata* ('irregularly-gangliated'), applied to the M. in opposition to the term *Homogangliata*, applied to *Annulosa*, in respect of the regular and defined nature of the nerve-centres in the latter animals. In *Molluscoida* the nervous system consists of a single nerve-mass only. (4) The *symmetry* or shape of the body in M. is typically *bilateral* or 'two-sided.' But being more developed to one side than the other, the *bi-lateralism* of M. is described as existing on each side of a curved median line, instead of being described or defined by a straight line, as in *Annulosa* and *Vertebrata*. In higher M., the lower or ventral surface of the body is specially adapted to form a *foot*, which becomes greatly modified in the various classes—forming the true 'foot' in *Lamellibranchiata*, the crawling-disc of *Gasteropods*, and the tentacles or arms of *Cephalopods*, &c. The foot is wanting in *Molluscoida*. (5) In all higher M. a distinct heart exists. The heart, moreover, consists of at least two chambers. In lower M. (as in *Polyzoa*) a distinct heart may be wanting. In higher M. there is no tendency to form *compound colonies* of animals, such as is illustrated by the *Polyzoa* and *Tunicata* amongst lower M.; and in the higher M. reproduction is always subserved by *sexual methods*.

The *digestive system* of M. comprehends a mouth, occasionally surrounded by tentacles (*Polyzoa*), and containing, in higher forms, jaws or a dental apparatus; the jaws of cuttlefishes, and dental apparatus or *odontophore* of *Gasteropods*, exemplifying the structures of the mouth in M. In *Lamellibranchiata* no hard parts exist in the mouth. The alimentary tract itself includes a gullet, stomach, and intestine; the anus or vent frequently being in the same plane as the mouth. A large *liver* is usually developed, and *salivary glands* are generally represented. The *kidneys* of M. are represented in such classes as *Lamellibranchiata* and *Gasteropods* by the *Organs of Bojanus*, a structure adapted for separating waste nitrogenous matters from the blood. The heart of higher M. is purely *systemic* in its nature, i.e., it serves solely to propel pure blood through the body; the venous blood returning to the breathing organs through the veins without the direct action of the heart. In *Cephalopods*, rudimentary or subsidiary hearts may be formed by dilatations of the veins at the bases of the gills; these so-called 'branchial hearts' serving to propel venous blood into breathing-organs. The *respiratory* or *breathing function* may be performed in M. by ciliated tentacles (*Polyzoa*), by a breathing-sac (*Tunicata*), by elongated 'arms' (*Brachiopoda*), by true gills (*Lamellibranchiata*, *Gasteropoda*, *Pteropoda*, and *Cephalopoda*), or by a lung-chamber (snails, slugs, &c.). In some low forms of M. the general body-surface may constitute the breathing-organ (e.g., some *Pteropods*).

The *nervous system* of M. has been already described. The *cephalic ganglia* appear to regulate the sensory apparatus; the *pedal ganglia* supply the muscular system with nerve-filaments, and hence may be named the *motor centres* of M.; and the *branchial ganglia* supply the viscera generally, and hence may be regarded as functionally corresponding with the *Sympathetic nervous system* of the higher animals. *Organs of sense* are developed in varying degrees of perfection in M. Eyes of

simple structure are developed in some Lamellibranchiates; such organs being represented by the row of colour-spots seen around the margin of the *mantle* in the *pectens* or scallop-shells. In some Tunicata, colour-specks, probably visual in function, exist just within the mouth-aperture. Tentacles, or organs of touch, are present in many M.; these being well seen in the snails and Gasteropods generally, in Polyzoa (where they subserve respiration), and in Tunicata. The arms of Cephalopoda subserve touch and prehension as well. The sense of hearing is represented in higher M. by *auditory vesicles* usually placed near the foot; while in some few M. an *olfactory* apparatus is supposed to be represented.

The sexes are distinct in many M., but, as in snails, &c., male and female organs may be found existing in one and the same individual. The copulation of two such *Hermaphrodite* individuals, curiously enough, appears necessary for the fertilisation of the eggs. Subsidiary glands (*nidamental glands*) are frequently developed in connection with the generative system of M.; these structures serving (as in Gasteropods and Cephalopods) to invest the eggs with tough outer capsules. The classification of M. is represented in the following table, and the chief characters of the various classes are described in such articles as BRACHIOPODA, LAMELLIBRANCHIATA, &c. :—

Mollusca.	Classes.
DIVISION I.—MOLLUSCOIDA, or LOWER MOLLUSCA.	1. <i>Polyzoa</i> : Ex. Sea-Mats, &c.
Mollusca characterised by the low organisation of heart and nervous system as compared with the higher Mollusca.	2. <i>Tunicata</i> : Ex. Sea-Squirts.
	3. <i>Brachiopoda</i> . Ex. Lampshells.
	4. <i>Lamellibranchiata</i> : Ex. Oysters, Mussels, Clams, &c.
	5. <i>Gasteropoda</i> : Ex. Whelks, Snails, &c.
DIVISION II.—HIGHER M., or M. PROPER.	6. <i>Pteropoda</i> : Ex. 'Sea-butterflies.'
	7. <i>Cephalopoda</i> : Ex. Cuttlefishes.

Fossil M.—M. are abundantly preserved as fossils, owing to their having *hard parts* in the form of shells. They are represented in the oldest rocks, and commence their existence in the *Cambrian Period*, when no less than five classes (*Polyzoa*, *Brachiopoda*, *Gasteropoda*, *Pteropoda*, and *Cephalopoda*) are represented by fossil species. In the *Silurian Rocks*, the Brachiopoda were so abundant that the Silurian Period has been named the 'age of Brachiopods.' The Tetralbranchiate (or four-gilled) cuttlefishes attained the height of their development in the Silurian and Mesozoic rocks, and are represented in existing seas by one existing species only—the Pearly Nautilus (see NAUTILUS). The Lamellibranchiates first appear in the Lower Silurian; but of the soft-bodied sea-squirts, or Tunicata, no record has been preserved in the history of fossil forms.

Molluscoïda, a subdivision of the *Mollusca* (q. v.)—regarded by some zoologists as a distinct sub-kingdom of the animal world—represented by the lampshells, *Brachiopoda* (q. v.), sea-mats, &c., or *Polyzoa* (q. v.), and by *Tunicata* (q. v.), or 'sea-squirts.' The M. are decidedly of lower organisation than the *Mollusca Proper*, or Higher Mollusca. They exhibit inferiority (1) in the absence, or at most rudimentary nature, of the heart; (2) in the nervous system consisting of a single ganglionic mass, whereas in Mollusca Proper it consists of three well-marked ganglia; (3) in the absence of a foot; and (4) in the presence of a sexual form of reproduction, such as *budding* or *gemination*, well seen in the sea-mats (*Polyzoa*) and certain tunicates. It is doubtful, however, whether these differences entitle zoologists to separate the M. completely from the Mollusca.

Moll'witz, a village of Prussia, in the province of Silesia, 4 miles W. by S. of Brieg. Pop. 645. It is famous as the scene of a great victory won by Friedrich II. of Prussia over the Austrian Marshal Neipperg, April 10, 1741.

Mo'loch, properly *Mo'leah* (Heb. 'king,' cf. Baal, 'lord'), and perhaps also *Miloom*, although some consider the last to be a distinct deity, was the national god of the Ammonites (1 Kings xi. 5, 7). He was one of the Fire or Sun-gods common to all the Semitic tribes, who had brought that form of

Nature-worship with them from their original home in the high-lands of Armenia. As Baal and Astarte represented the regenerative power of Nature, the fructifying influence of the Sun, M. represented its destructive side, and was worshipped under the symbol of a flame of fire. The rites with which he was worshipped were human sacrifices, dedication of the first-born, purifications and ordeals of fire, mutilations, vows of perpetual virginity, &c. This worship was first established at Jerusalem by Solomon (1 Kings xi. 5, 7), and was kept up till the time of Josiah (2 Kings xxiii. 10, 13). It was restored by Josiah's son and successor (xxiii. 32), and was only completely rooted out by the Babylonish Captivity. The Jewish Rabbins have contended that human sacrifices were not offered to M. by the Israelites, for the children offered to him were not burned, but only made to pass between two fires; and this theory is a favourite one in modern times. But it is maintained, on the other hand, that the allusions to actual slaughter are too plain to be explained away: e.g., in Deut. xii. 31, Ps. cvi. 37, 38, Jer. vii. 31, Ezek. xvi. 20, 21, xxiii. 37, and 2 Chron. xxviii. 3 (cf. 2 Kings xvi. 3).

Moloch Lizard (*Moloch horridus*), a species of lizard found in Australia, and presenting a singular appearance from its being covered with strong plates and spines, while the head bears two prominent processes. A protuberance armed with two spines occurs in the back of the neck.

Molt'ke, Hellmuth Karl Bernhard, Graf von, Chief Marshal of the German Empire, is the son of an officer of a Mecklenburg family, and was born at Gnewitz, October 26, 1800. Soon after his birth his parents settled in Holstein, and in his twelfth year M. was sent to Copenhagen military school. He obtained a lieutenancy in the 8th Prussian regiment of infantry in 1822, and studied at the Military Academy and at the Divisional School, Frankfurt-on-the-Oder. He went to Turkey in 1835, and receiving a commission from the Porte, served in the campaign of 1839 against Mehemet Ali, returning to Prussia in 1845. He became a member of the Grand General Staff in 1848, chief of the Staff of the 4th Army Corps in 1848, chief of the Grand General Staff in 1858, and lieutenant-general in 1859. In the last year he accompanied the Austrian headquarters during the Italian campaign. As chief of the Prussian staff, he planned the invasion of Denmark in 1864. His magnificent generalship crushed the Austrian army at Sadowa in 1866, when he received the order of the Black Eagle. In the Franco-German war he held the supreme command of the four great armies which simultaneously entered France. To him pre-eminently belongs the honour of that unparalleled and unbroken series of great victories, from the battle of Weissenburg to the capitulation of Paris, which humbled the military power of France, and inspired all Germany with patriotic pride. He was created Graf (Count) 1870, field-marshal January 1871, and chief-marshal September 1871. M. has never been surpassed as a strategist, in perfect mastery of detail, in calm clear foresight of all the chances of a gigantic campaign. Usually a silent thinker, a speech he made in the German Reichstag in the spring of 1877, calling attention to the military activity of France and the necessity of increased watchfulness on the frontier, created an exaggerated feeling of alarm. He has written the following works, all-important to the military student, *Der Russisch-Türkische Feldzug* (1835), *Briefe über Zustände und Begebenheiten in der Türkei* 1835–39 (Berl. 1841; Eng. trans. 1877); *Der Italienische Feldzug von 1859* (3d ed. Berl. 1870), and *Der Deutsch-Französische Krieg* (Berl. 1873 et seq.). An English translation of his *Observations on the Influence that Arms of Precision have on Modern Tactics* was published in 1871.

Moluccas, or *Spice Islands*, a great, widely-scattered group in the E. Indian Archipelago, belonging to the Dutch, and lying between Celebes on the E. and Papua on the W.; lat. 3° S.—6° N., and long. 126°—135° E. Area 45,000 sq. miles; pop. (1873) 348,111. By far the largest are Gilolo and Ceram, and other important members of the group are Amboyna, Banda, Buru, Ternate, Tidore, Bathian, Makian, Motir, and Obi. They are all of volcanic origin, very irregular in outline, and rise abruptly in grand mountain masses, clad to the summit with luxuriant forests of teak, ebony, sandal, iron, satin, palm, and bread-fruit trees. Among the natural products are rice, sago, cotton, indigo, coffee, sugar, and spices. Amboyna yields the best

cloves, Banda and the Uliassers the best nutmegs. Ternate, to the W. of Gilolo, is said, of all the islands, to produce the greatest variety of spices. Along the coasts there are valuable trepang and pearl fisheries. The southern portion of the M. is governed directly by the Dutch through the Residencies of Banda and Amboyna, the northern part indirectly through the sultans of Ternate and Tidore. Amboyna is the capital of the M., and after Batavia, the chief seat of Dutch commerce in Oceania. The original inhabitants are Malays, but Arabs, Hindus, Chinese, Japanese, and Mestizoes are numerous. In the islands indirectly governed, the inhabitants, mostly Mohammedans, are greatly given to piracy. The M. were visited and claimed in 1521 by the Portuguese, who subsequently behaved to the inhabitants with vile deceit and cruelty. Assisted by the natives, the Dutch drove out the Portuguese in 1607, and have since remained masters of the islands, except from 1810 to 1814, when they were subject to the English. See separate articles on AMBOYNA, BANDA, BATSHIAN, GILOLO, &c.

Molybdenum (symbol Mo, atomic weight, 96), a silvery-white, hard, almost infusible metal, discovered by Hahn in 1782. Its chief source is the ore *molybdena*, which is the bisulphide of M. (MoS_2), and which when roasted in air to a dull red heat and digested with strong ammonia yields molybdate of ammonia. By the addition of hydrochloric acid, *not in excess*, molybdic acid (MoO_3) is precipitated. The metal is obtained by reducing the acid with charcoal at a white heat. Its properties are little known, and the rarity of the metal renders its compounds of small moment.

Mombaz', a town of E. Africa, in the territory of the Sultan of Zanzibar, and on a coral islet at the mouth of two rivers. The harbour is good, but the town, inhabited by half-caste Arabs, is ruinous and filthy. It was visited by Vasco da Gama in 1497, and from 1529 to 1720 it was held by the Portuguese, who erected a strong rock-fort, the walls of which are still standing. M. was occupied by the English in 1824, but abandoned two years later. Pop. 10,000.

Momein', a considerable town in the Chinese province of Yunnan, on the edge of the plateau of Yunnan, more than 5000 feet above the sea, about 135 miles N.E. from Bhamo, the farthest navigable point on the Irrawaddy River in British Burmah. It was formerly the centre of a valuable transit trade in minerals, &c., and subsequently a rallying-point of the Panthays or Mohammedan rebels. M. was the farthest point reached by an official British exploring expedition into W. China in 1867. It is said to have been since almost destroyed by the victorious Chinese. See Dr. Anderson's *Man-dalay and Momein* (Lond. 1876).

Moment of a velocity or of a force about a given point is the product of its magnitude into the perpendicular from the point upon its direction. Similarly the M. of momentum of a moving body about a given point is the product of the momentum into the perpendicular from the point upon the direction of motion of the body. The sum of the moments of momenta of a system of mutually acting particles about any axis is constant. The *M. of Inertia* of a system of particles with reference to any axis is the sum of the products of the mass of each part into the square of its distance from the axis, and is represented mathematically by Σmr^2 . If *M* be the mass, and *k* be taken so that $Mk^2 = \Sigma mr^2$, *k* is called the radius of gyration. It is an important quantity in the mathematical discussion of rotations.

Moment'um, or **Quantity of Motion** of a rigid body moving without rotation is proportional to the mass and velocity conjointly. Hence, defining unit M. as the M. of unit mass moving with unit velocity, the M. of mass *m* moving with velocity *v* is measured by the product *mv*. M. is therefore a *vector* or directed quantity; and momenta are to be compounded like other vectors, such as velocities and forces. A force acting upon a given mass is measured by the M. it produces in unit time; and the unit force is of course that which produces unit M. in unit time. Taking the pound, foot, and second as the units of mass, length, and time respectively, let us find the value of the poundal or absolute unit of force. A body falling for one second at the equator acquires a velocity of 32.088 feet per second—a M. therefore of $m \times 32.088$. The unit force would give to the body a velocity of 1 foot per second; hence the value of the force of gravity at the equator is, in terms of the absolute

unit, 32.088. Consequently 32.088 is the number of absolute units or *poundals* which measure the *weight* of a pound at the equator. In other words the poundal is equal to the weight of about half an ounce.

Momm'sen, Theodor, an illustrious German scholar and historian, born at Garding in Slesvig, November 30, 1817, was educated at the Altona Gymnasium (1834-38), studied law, philology, and history at Kiel till 1843, and travelled in France and Italy (1844-47). In 1848 he accepted a call to the chair of law in the university of Leipsic, but, losing the post through his action in the political troubles of that and the following year, was successively appointed Professor of Roman Law at Zürich (1852), Breslau (1854), and Berlin (1858). In 1875 he returned to Leipsic as Professor of Jurisprudence. As an historian, M. has won for himself a world-wide reputation. His *Römische Geschichte* (5th ed. 3 vols. Berl. 1868-70; English trans. by W. P. Dickson, Lond. 1862-63) gives to the general reader the results of his own and others' researches during the last fifty years in the fields of archaeology, philology, and political economy, and, while agreeing generally with the earlier work of Niebuhr, clears up many points which that writer had necessarily left in obscurity. Altogether it may be said that his way of treating his materials, though strictly critical, is eminently constructive. His political opinions tinge his narrative with the hues of life. No German historian has ever approached the lucid vigour, the trenchant eloquence, and the picturesque pomp of his style. Besides the *Römische Geschichte*, M. has written *De Collegiis et Sodalitibus Romanarum* (Kiel, 1843), *Oskische Studien* (Berl. 1845); two 'epoch-making' works, executed in conjunction with Henzen for the Berlin Academy, *Corpus Inscriptionum Neapolitanarum* (Leips. 1851), and *Corpus Inscriptionum Latinarum* (Berl. 1863); *Geschichte des Römischen Münzwesens* (Berl. 1860); *Römische Forschungen* (Berl. 1861); *Digesta Justiniani Augusti* (Berl. 1868-70); *Römisches Staatsrecht* (Leips. 1871), &c. During 1877 M. made a tour through Italy to complete his study of old Roman inscriptions, and was everywhere received with civic honours. Never since the days of Erasmus has a scholar been so royally welcomed.

Momordica, a small genus of cucurbitaceous climbing plants with fleshy fruits, which are prickly or warted externally, and burst when ripe into irregular valves. An Indian species named *M. Charantia*, now frequently grown in hothouses, is very ornamental, particularly when the ripe warted fruit bursts, and shows the seeds covered with their fleshy red ail. Another Indian species, *M. mixta*, has large creamy flowers and red prickly fruit shaped like a bullock's heart. The fruit of *M. balsamina* infused in oil forms a vulnerary in repute in some Eastern countries. The 'squirting cucumber' represented in the woodcut, is by recent systematists separated into a genus called *Ecballium*, but it was long known as *M. elaterium*, and gave name to the drug *Elaterium* (q. v.).

Mompox', a town of Colombia, S. America, on the Magdalena, 110 miles S.E. of Cartagena, has some trade and ship-building. Pop. 10,000.

Mon'achism (from Gr. *monachos*, 'a monk'), means the monkish life in all its forms. Christian advocates of the system have always maintained that it owes its origin to the Gospel, which indicates a vow of poverty as a step towards perfection (Matt. xix. 16-29). Contemplative asceticism, however, is a thing of the remotest antiquity. Monks have been as common among the Buddhists of India and Thibet as ever they were in Europe. The Neo-Platonists recommended M., and the Jewish Nazarites, Rechabites, Essenes, and Therapeutæ, all lived more or less after this manner. Persecution was probably the chief cause of Christians first betaking themselves to live in the desert

Momordica elaterium.

(see EREMITES). During Maximian's persecution a hermit Antonius excited much attention by his extravagant asceticism, attracted a number of imitators around him, and has received the name of the Father of M. (see ST. ANTHONY). When a number of hermits had been brought together in this way, Pachomius (about 340) founded a habitation on the island of Tabenna, in the Nile, where they might live together, a *koinobion* (Gr. *koinos*, 'common,' *bios*, 'life'), with a system of rules for their government, including vows of poverty, chastity, and obedience to the president (Gr. *abbas*, *archimandrite*). About the same time similar societies were founded—by Amun, on the Nitrian mountain, by Macarius (the elder), in the desert of Sketis, and by Hilarion, in the desert of Gaza. The peculiarities of the M. of this period consisted in solitariness, manual labour, spiritual exercises, and restraint of the bodily appetites, for the sake of mortifying the flesh and allowing the spirit the better to contemplate divine things. It was received in the East with enthusiastic admiration, and the number of monks soon increased to an enormous extent. 'As there were no more persecutions, and no more opportunities of martyrdom; as Christianity had even acquired external dominion; the erroneous notion was spread abroad that there was no longer an opportunity in the world for the full exercise of Christian virtue. The general corruption or consciousness of individual guilt caused many to seek solitude. Many sought escape from the oppressive circumstances of life. Others wished to make a figure and obtain an influence. Others were attracted by sloth; and lastly, others were drawn away by mere imitation.' The most distinguished teachers of the Church eulogised the system; examples of it were found in pre-Christian times (e.g., Elijah and John the Baptist); the Therapeutæ were shown to have been Christians (Acts ii. 44; iv. 32); and, in short, the original condition of the first Christians was shown to have been a state of M.

Hitherto Monasteries (q. v.) had been confined to the deserts, but Basil the Great (329-379) established one near Cæsarea in Cappadocia, and from this time they became common near the haunts of men. Meantime M. had been developed in many various forms. The *Rhombotri* or *Sarabaitæ* merely lived an ascetic life in society. The *Boskoi* wandered about in companies in Mesopotamia. The *Canobites* lived together in convents. The *Anchorites* (q. v.) were distinguished for their ingenious modes of crucifying the flesh, the highest point in the art perhaps being reached by the 'Pillar-Saints' (q. v.), imitators of Simeon, who in 420 took up his abode on the top of a pillar near Antioch. There were also convents for females (*Ascetrixæ*, *Monastrixæ*, *Castimoniales*, *Sanctimoniales*, *Nonnæ*) as early as for males.

In the West, M. was at first regarded with contempt as a piece of Oriental fanaticism, and when it was introduced, partly owing to this feeling and partly owing to the difference in climate, it was in a far less ascetic form. Monasteries were established in Italy (at Milan and Rome, and on the small islands on the coast) and in Gaul in the end of the 4th c. In Africa, notwithstanding the praise bestowed on the system by Augustine, the hatred of M. was kept up longer than almost anywhere else; its converts were for long found only among the lower classes.

As M. was considered the perfection of Christianity, it soon came to be regarded as the nursery for the clergy, and especially for bishops. The next idea was to transfer it altogether to the clergy, on whom Celibacy (q. v.) and a strict monastic life were imposed by zealous advocates of the system. A new form was given to M. by Benedict (q. v.), whose system (529) was distinguished especially by exacting a promise from all who entered a monastery never to leave it again. This system soon spread in Italy, Gaul, and Spain, and thus was established the first monastic order—the Benedictines (q. v.)—under a particular 'rule.' In these primitive times monasteries were a beneficial influence wherever they were planted, for the monks 'reclaimed waste lands, educated the young, removed, both by precept and example, the contempt for labour which slavery had produced, gave the first impulse to art by the ornamentation of churches, handed down to posterity the history of their time in chronicles, and by their copyists preserved to it the writings of antiquity.' But in the rude times of the middle ages, when monasteries were bestowed as fiefs on persons not monks, and abbots strove for political power, 'all discipline was neglected, and disorders and excesses of all kinds prevailed among monks and nuns.' An attempt at reformation was made in the 10th and 11th centuries. The rule of St. Bene-

dict was restored in the convent of Clugny by the abbot Berno (910), and additional rules were added by the abbot Odo (927-941), so as to form an essentially new order—Cluniacensis. Similar reforms were carried out in Italy and Germany a little later (about 1020-70). About the same time a new development of M. appeared in the *donati* or *oblati*, who yielded up themselves and all their property to the service of the monastery; the *fratres conversi*, lay brothers who managed the household department, and the *fratres conscripti* or *confratres*, who had a share in the spiritual blessings of the brotherhood.

The reformation above referred to was unfortunately followed by fresh decadence; and this phenomenon has uniformly repeated itself every time there has been a reform, and even with every new order of monks that has been formed. Reputation for sanctity brought increase of wealth, and increase of wealth was accompanied or followed by desire of independence, ambition, and love of pleasure. Every new order, however fair it might promise at first, invariably developed in a short time all or some of the evils exhibited by the others. So invariably did this occur, and so great was the confusion produced in the Church by the innumerable orders, that in 1215 Pope Innocent III. forbade the formation of any new ones. But scarcely had the law been passed when the Pope was constrained to grant exemption from it in favour of the Mendicant Orders (q. v.), till further multiplication of these again was forbidden by Pope Gregory X., 1274.

Yet another form of M. was developed in the 12th c. in connection with chivalry. The idea that fighting with the infidel was one of the highest deeds of piety, and of the greatest value in working out one's salvation was a highly popular one in such a warlike age, and went far to compensate for the self-denial of M. Thus several orders of monks formed themselves into orders of monkish knights, e.g., the Knights Hospitallers (q. v.), or new orders were formed on this principle, e.g. the Knights Templars (q. v.), in the course of the 12th and 13th centuries.

Amid the great efforts to reform the Church, which were made in the 15th c., the monastic orders, with their general corruption, could not be overlooked. But notwithstanding all the efforts to reform them that were put forth by the Popes and Church Councils, complaints of the corruption of M. never ceased during this period, and the evil was not cured till the Reformation of the 16th c., when the system was entirely discarded by the Protestants; and in so far as it has been kept up in the Roman Catholic Church, the strictest discipline has as a rule been maintained. See Gieseler's *Lehrbuch d. Kirchengeschichte* (Eng. trans. 1855.)

MONACO (the *Monaci Pontus* of antiquity), capital of the tiny principality of M., on the coast of the department Alpes Maritimes, 5 miles N.E. of Nice by rail. It is picturesquely situated on a bold rock, round which wind beautiful promenades. Many visitors are attracted by the mildness of the climate in winter and by the sea-bathing in summer, but perhaps a greater inducement is the 'tapis vert' at the Casino, for M. is a legalised gambling place. There is some export trade in oil, oranges, citrons, perfumery, 'artistiques,' liqueurs, pottery, &c. With the surrounding territory M. has an area of 6 sq. miles. Pop. of the principality (1873), 5741; of the town, 2667. M. has belonged to the Grimaldi, a Genoese family, since 968. For a time (from 1848) it was dependent on Sardinia, and in 1861 the adjoining communes of Mentone and Roccabruna were sold by Carlo III. to France.

MONAD, the name given to some of the lowest forms of living beings. They exist as exceedingly minute specks of protoplasmic matter, and occur in stagnant water, in infusions of animal and vegetable matter, and in like situations. Some of the monads, at least, are believed by competent authorities to be of vegetable nature, and there appears little doubt, from recent researches, that many so-called monads represent stages in the development of the *Protozoa* (q. v.). Many monads are provided with vibratile *cilia* or filaments, used in locomotion.

MONAD (Gr. *monas*, 'unity') in Leibniz's system of philosophy, is the primary element of matter. Monads are simple substances, are neither extended, figured, nor divisible, and form by aggregation all compound substances. Created and yet simple, they are necessarily indestructible, and are in reality the true atoms of nature. Leibniz divides them into two classes—those which though they have perception lack consciousness, and those which to perception add a certain consciousness called *apperception*.

The members of the latter class differ according to the degree of their consciousness—there being a gradation from lower to higher types. The Deity is the *Prime M.*, or *M. of Monads*. The term *M.* is used vaguely in the various systems of Zeno, Leucippus, Democritus, &c.; but Leibniz was the first to systematise the conception.

Monadnock, a solitary and conspicuous mountain in the S.W. of New Hampshire, U.S., which rises from the swell of land E. of the Connecticut River to a height of 3180 feet.

Monaghan (Irish Gael. *Muineachán*, 'a place abounding in little hills'), an inland county of Ireland, province of Ulster, is bounded N. by Tyrone, W. by Fermanagh, S. by East Meath and Cavan, and E. by Armagh and Louth. Area, 496 sq. miles; pop. (1871) 114,969. The surface is hilly, especially in the E. and N.W., where the Slieve Beagh Mountains reach 1254 feet. There are many bogs and small lakes. The chief rivers of *M.* are the Blackwater (for 12 miles the N.E. boundary), and (in the S.W.) the Finn, an affluent of the Shannon. The Silurian formation, which occupies the greater part of the country, is capped in the N.W. by the carboniferous limestone. There are valuable quarries of lime, marble, and sandstone. The soil of *M.* is in general loam resting on clay, and is still ill drained in the W. and N.W. In 1876 there were 139,739 acres under crops (chiefly flax, oats, wheat, and potatoes); 143,698 in grass; 5044 in plantation; and 29,679 bog, waste, and water. *M.* has (1876) 10,838 horses, 85,555 cattle, 15,999 sheep, and 32,066 pigs. The county is traversed by the Ulster Canal, and by one branch and two main lines of railway. The towns are *M.* (q. v.), Clones, and Carrickmacross. *M.* returns two members to Parliament. The chief antiquities are the 'Worm Ditch' at Scotchouse, and the round towers at Clones and Inniskeen.

Monaghan, the county town of *M.*, Ireland, on the Ulster Canal, and 16 miles S.S.W. of Armagh by rail. It has three principal streets, diverging from a square called the 'Diamond.' There are in *M.* an Episcopal church, a Roman Catholic cathedral (built 1862-68) and college, and several Dissenting chapels. Linen is manufactured, and there is considerable trade in agricultural produce. Pop. (1871) 3760.

Monastery (from Eccl. Gr., *monastḗs*, 'a monk,' and that from Class. Gr. *monos*, 'solitary') meant originally the dwelling of a single monk, as distinguished from *cenobium* (Gr. *κοινός*, 'common,' and *bios*, 'life'), the habitation of a number of associated monks; but afterwards the name was used in the West with the same meaning as *cenobium* in the East. The head of the *M.* was called the *Abbas* (Aram. 'father'), *hegumenos* (Gr. 'president'), *archimandrite* (Gr. from *archōn*, 'ruler,' and *mandra*, 'a fold'). Under him were other officers: e.g., the *cenobiaris* and *decanus* ('dean'), who presided over a hundred and ten respectively. In later times, under the generic name of *M.*, there were the specific names of Abbey, which was governed by an Abbot, and Priory, governed by a Prior, an inferior kind of abbot or abbot-vicar, to which Commandery and Preceptory corresponded in the military orders. In the mendicant orders the proper name was Friary or Convent. The houses of females are Convents or Nunneries.

Monasticism. See MONACHISM.

Monastir, *Toli*, or *Bitolia* (anc. *Octolophum*, or *Heraclea*), a town of European Turkey, vilayet of Selanik, in a wide plain at the E. base of the Peristerie Mountains, and on the Dragor, 95 miles W.N.W. of Saloniki. The seat of a governor-general, and a garrison town, it has 11 mosques, extensive bazaar, and an important transit trade with Constantinople, Trieste, Vienna, &c. The town is named from the neighbouring monastery (*Monastir*) of Bukova. Pop. 45,000.

Monbodd'o, **James Burnet**, Lord, a Scotch philosopher, was born at Monbodd'o, Kincardineshire, 1714. He was educated at Laurencekirk and Marischal College, Aberdeen, studied law at Groningen in Holland, was called to the Scotch bar in 1738, and rose to the bench in 1767. His book on the *Origin and Progress of Language* was published in 1771-76; and another work on *Ancient Metaphysics* appeared immediately before his death, which took place at Edinburgh, May 26, 1799. *M.* was an able judge, but in all other matters an eccentric enthusiast. He endeavoured to conform his manner of living to that of the Greeks and Romans. He is chiefly known as the author of a fantastic monkey-development theory, the reasonableness of which

may be judged by his explanation of how men came to have no tails—they wore them off by sitting! Yet his writings abound with shrewd sense and wit.

Monca'da, **Francisco de**, **Conde de Osona**, born of an illustrious Spanish family at Valencia, December 29, 1586, rose to be Privy-Councillor and Minister of War, Ambassador to the court of Vienna, and Generalissimo of the Spanish forces in the Netherlands. He fell at the siege of Goch, a fortress of Kleve, in 1635. His fame as a Spanish classic rests on his *Expedicion de los Catalanes y Aragoneses contra los Griegos y Turcos* (Barcel. 1623), the materials for which he borrowed from the Catalan chronicler Muntaner; but he also wrote a *Vida de Boecio* (Frankf. 1642), and other works. See Ticknor's *History of Spanish Literature* (vol. iii. p. 146).

Moncalieri, a town of Italy, province of Turin, 5 miles S. of Turin by rail, on the right bank of the Po, which is here crossed by a bridge of seven arches. Among its fine buildings is a chateau where Victor Emmanuel I. died in 1823. *M.* has a large October cattle fair, and commands a splendid view of the Alps and plains of Piedmont. Pop. (1874) 9994.

Moncreiff, an old Scottish family, which received a baronetcy in 1625. The most distinguished members of the family are:—**Sir Henry Wellwood M., D.D.**, eighth baronet, an eminent clergyman of the Church of Scotland, born at Blackford Manse in February 1750. From 1775 till his death in 1827 he was minister of St. Cuthbert's, Edinburgh, and was highly esteemed both as a pastor and a preacher. He took an active part in the administration of the affairs of the Church, and was the leader of the evangelical party. He was elected Moderator of the General Assembly in 1785. His chief works are the *Evidences of the Jewish and Christian Revelations, Account of the Life and Writings of John Erskine, D.D.*, and a collection of *Sermons*, in 3 vols.—2. His second son, **James Wellwood M.**, born 13th September 1776, succeeded as ninth baronet, and took rank among the foremost members of the Scottish bar, at that time adorned by some of the most illustrious lawyers Scotland has produced. He was raised to the bench as Lord *M.* in 1829, and his judicial career materially enhanced his reputation. He died 30th April 1851.—3. He was succeeded by his eldest son, **Sir Henry Wellwood M.**, born in 1809, ordained minister of East Kilbride in 1836, and after the disruption translated to Free St. Cuthbert's, Edinburgh. He is the seventh baronet in lineal succession who has been a minister of the Church of Scotland. *M.* is senior principal clerk of the General Assembly of the Free Church, was elected its Moderator in 1869, and obtained from the University of Edinburgh in 1860 the degree of D.D. His chief works, in addition to various pamphlets, are, *Credits and Churches in Scotland* (1869), *The Claim of Right* (1877), and *Free Church Practice* (1877).—4. **James Wellwood M.**, second son of (2), was born at Edinburgh, 29th November 1811, educated at the High School and University of his native city, and passed advocate in 1833. After holding the office of Solicitor-General for Scotland for 14 months, he became Lord Advocate in 1851, when Lord John Russell was Premier, and this appointment was renewed under the governments of Lord Aberdeen, Lord Palmerston, Lord Russell, and Mr. Gladstone. He was M.P. for the Leith Burghs from 1851 till 1859, for the city of Edinburgh from 1859 till 1868, and for the universities of Glasgow and Aberdeen from December 1868 till October 1869, when he was appointed Lord Justice-Clerk. During his long Parliamentary career, *M.* rendered important service to his party in the debates of the House of Commons, and his name is most honourably identified with the efforts made by Liberal governments, of which he was a member, to establish a system of national education in Scotland. Of the educational measures introduced by him, that of 1861, for increasing the salaries, fixing the examinations of teachers, and for the abolition of tests, alone passed into law; but his prolonged and devoted labours undoubtedly prepared the way for the adoption of the Act of 1872. He was elected Dean of the Faculty of Advocates in 1858, and Rector of the University of Edinburgh in 1868. He is a contributor to the *Edinburgh Review*, and author of a work of fiction entitled *A Visit to my Discontented Cousin*, which originally appeared in *Frazer's Magazine*. He was created a baronet in 1871, and in 1874 was raised to the Peerage of the United Kingdom, under the style of Baron *M.* of Tulliebole.

Mondo'vi, a town and fortress in N. Italy, province of Cuneo, on an affluent of the Tanaro, 9 miles E. of Cuneo by rail, lies among vineyards and chestnut woods, 1824 ft. above the sea. M. is a bishop's see, has a fine cathedral of the 15th c., manufactures silks, woollens, cottons, and paper, and has considerable trade. Pop. (1874) 16,543. Here the French under Masséna and Augereau defeated the Austro-Sardinian forces under Beaulieu, 21st April 1796.

Mone'sia Bark is derived from a Brazilian species of *Chrysophyllum*, and a preparation of it is used as a stomachic and alterative in leucorrhœa, chronic diarrhœa, &c. The bark is full of a milky juice, but after drying becomes heavy, brown, and hard, with a taste at first sweet, afterwards astringent and bitter. *Monesin* is the active principle.

Mon'ey (Fr. *monnaie*, from Lat. *moneta*) is the measure and standard of value and the medium of exchange. It is also a convenient store of value. All these functions are separable; e.g., in Elizabeth's time silver was the measure of value, gold was used for large payments in quantities depending on its current value in silver, and corn was the standard of value in the leases of college lands. The early use of cattle as M. is traceable in the words *pecunia*, fee; *kalema*, skat, and capital. The wampum beads and cowry shells of N. America are still more primitive. Corn (which is still deposited in Norwegian banks), oil, cacao nuts, tobacco, eggs, and dried codfish, and other kinds of raw produce have also been used. The cotton pieces of Guinea, and libongos, or straw mats of Angola, cubes of tea in Tartary, and the Scotch nails mentioned by Adam Smith are among the manufactured articles which have served as M. The qualities of good M. seem to be: (1) that it shall have substantial intrinsic value generally appreciated; (2) it must be portable—gold can be taken from London to Paris at a cost of 4 (including insurance)—£5 in Spartan currency (iron) would weigh a ton; (3) it must be practically indestructible; (4) it must be homogeneous, so that the equal weights will have the same values; (5) it must be divisible without great loss (gold loses in melting about 1s. 4d. per ounce); (6) it must not be too variable, as it is used as a standard of value in long contracts; (7) it must be easily known as intrinsically genuine, and must be able to receive and retain a mint mark. In the earliest times the various metals used as M. were not coined, but passed by tale, or number of pieces of the same weight and shape. The sycee silver, now used in China, seems to be a small shoe-shaped ingot, with an assay-stamp of doubtful value. Coins proper are ingots, of which the weight and fineness are certified by the integrity of designs impressed on the surfaces of the metal. The objects in selecting a form of coin are to prevent counterfeits and the fraudulent removal of metal from the coins, to minimise the depreciation by tear and wear, to produce an artistic and historical monument of the nation. The last object has not been attained in Great Britain. The standard unit of value is an entirely arbitrary weight of the standard metal. Hence, it seems not to matter much whether or not we have, as M. Chevalier suggests, a universal standard unit of value corresponding with the metric system of weights. As in the case of the Old Eng. *mancus*, *meare*, *ora*, *thrimsa*, and shilling, the *monies of account* may be entirely different from the unit of value (1 lb. silver), and the current M. (silver pence and halfpence). We must also distinguish from standard M. such token M. as our bronze coinage, of which the legal value often varies 75 per cent. from the metallic value. M. which is legal tender, or which has what the French call *cours forcé*, is what under the Coinage Act (33 Vict. c. 10) a creditor must accept from his debtor, subject to liability for costs in an action for his debt. The popularity of M. depends very much on custom: thus, the Austrian mint has since 1870 issued Maria Theresa dollars for use in the Levant and N. Africa. There is a constant tendency in new M. to disappear from circulation. This is on account of the 'picking and calling' by bullion dealers, &c., who melt, export, or hoard the full weight M. 'Bad M. drives out good,' so that sovereigns are constantly circulating which are 6d. or 8d. below the standard. The chief systems of metallic money are: (1) currency by weight, which, as Aristotle says, was the oldest, and which still exists in the Chinese *tael* and elsewhere; (2) unrestricted currency by tale, in which the State would merely certify the weight of the various portions of metal: by the system of *parallel standards* the coins would circulate by tale at ratios varying according to the market values

of the metals; (3) single legal tender system, which has always been found insufficient, as when in England the want of a legitimate copper coinage was supplied by tradesmen's tokens; (4) the multiple legal tender system; (5) the composite legal tender, where subordinate token coins of a metal different from the standard of value and principal legal tender are recognised as tender for small amounts. International M. would no doubt facilitate commercial accounting and statistical inquiries, and would prevent a good deal of melting and recoinage which at present goes on. Its possibility is shown by the fact that several coins are received as tender beyond the nation by whom they were issued. The competing schemes for a decimal system in British money are known as the *Pound and Mil* system, which would alter the farthing 4 per cent to make it $\frac{1}{1000}$ of £1; and the *Penny and Ten Franc* system, which would reduce the penny 4 per cent. to make it $\frac{1}{100}$ of ten francs. For the higher forms of M. see PROMISSORY NOTE, BILL OF EXCHANGE, CHEQUE, BANK, &c.

Monferra'to, a former marquise of Italy, bounded N. by the seigniory of Vercelli, E. by Milan and Genoa, S. by the Apennines, and W. by Piedmont. It had an area of 1300 sq. miles, and was divided by the Tanaro, an affluent of the Po, into Upper and Lower M. Casale (q. v.) was the capital. Aleran, the founder of the House of M., was created a marquis by Otho II. in 995. His successors played a prominent part in the Crusades (q. v.), one of them, Konrad, being chosen King of Jerusalem (1192), and another, Guglielmo VII., marrying his daughter Yolande to the Byzantine emperor Andronicus Palæologus (1284). Theodoro, the second son of this marriage, succeeded to the marquise, which remained vested in his descendants, until, on the death of the last of the line (1533), it passed to the House of Gonzaga (q. v.). Since 1703 it has been incorporated with Savoy, and now forms part of the province of Turin.

Mongo, Gaspard, a celebrated French mathematician, was born at Beaune (Côte-d'Or), May 10, 1746. While studying at the military school at Mézières he invented his famous *Géométrie Descriptive*, and succeeded Bossut as tutor and professor there in 1772. In 1780 he was admitted to the Academy of Sciences. During the Revolution he took charge of the manufactories for supplying war-material to the army, and was the prime mover in the subsequent founding and organising of the École Polytechnique. In Italy, where he had been sent to take charge of the transport of artistic spoils to France, he met Bonaparte, whom he accompanied to Egypt. There he used well his opportunities as a scientific man. On his return to Paris in 1799 he resumed his work as a teacher, and was placed at the head of the École Polytechnique, but was deprived of his position under the reign of Louis XVIII. He died at Paris, July 28, 1818. As a mathematician M. has gained celebrity by his discoveries in pure geometry, while in the published papers of the Academy of Sciences his numerous memoirs upon the geometry of curves and surfaces, upon differential equations, and problems of attraction, attest his wide knowledge of the science. His chief works are *Traité Élémentaire de Statique* (1788; 7th ed. 1834); *Géométrie Descriptive* (1799; 6th ed. 1837); *Application de l'Algèbre à la Géométrie* (1805); and *Théorie des Ombres et de la Perspective*, published by Biissin (1819). See Dupin, *Essai historique sur les Services et les Travaux Scientifiques de M.* (Par. 1819).

Monghyr (*Mungir*), the chief town of the district of the same name, in Bengal, British India, on the right bank of the Ganges, 256 miles by rail N.N.W. of Calcutta. Pop. (1872) 59,698. It is favourably situated on a rock overhanging the river, both for commerce and defence. Its history goes back to an early period, and in 1763 it was chosen as the capital of Bengal by the last independent Nawab, Meer Cossim. M. contains a large fort, no longer kept up, and many temples, tombs, and other buildings. The trade, both by river and railway, is very considerable. There are manufactures of all sorts of iron-ware, including cheap guns, inlaying swords with gold and silver, cabinet work, boots, and dyeing.—The district of M., which lies on both banks of the Ganges, has an area of 3913 sq. miles; pop. (1872) 1,812,986. In the extreme S. it is hilly. The crops are rice, wheat, pulses, oil-seeds, indigo, and opium. The cultivating classes are not well off. The chief towns, besides M. town itself, are Shaikpura, Jummampur, Khaguriah, and Barheya. In 1876-77 the exports were valued at £430,000, chiefly oil-seeds, wheat, and other food grains, indigo, hides, and *ghee*; the imports at £314,000, chiefly piece-goods, salt, and sugar.

Mongolia, the land of the Mongols, and part of the Chinese empire, is a vast plateau 2000 feet above the sea, extending between Siberia on the N. and China Proper and Thibet on the S., and between Turkestan on the W. and Manchuria on the E. Area estimated at 1,304,000 sq. miles; pop. 600,000. M. is in great part occupied by the Desert of Gobi (q. v.), is girt by high mountain ranges (the Altai, Khin-ghan, &c.), and contains the head waters of the Amoor, Yenisei, and Angara. The climate is one of great extremes. Apart from the desert region the soil is mainly baked clay, affording root only to stunted bushes and tufts of saline grass. Yet in the more favoured spots the Mongol manages to rear herds of camels, horses, and sheep, which he exchanges for Chinese tea, corn, and manufactured goods. The chief centres of population are Urga and Karakorum, and in the N.W. are the trading stations Uliassutai and Kobdo. See *M., the Tangut Country, and the Solitudes of Northern Thibet*, by Lieut.-Col. N. Prejevalsky (Eng. trans. with notes by Col. Yule, Lond. 1876).

Mon'gols, The, a branch of the great Turanian family (see TURANIAN), appear in the 9th c. A.D. inhabiting the neighbourhood of Lake Baikal and the eastern portion of Siberia. They were divided into the M. proper, the Buriäts, and the Kalmuks (q. v.). These Genghiz Khan (q. v.), the founder of the Mongolian empire, welded in the 13th c. into a nation, which included also the Tungus (q. v.) and Turkic tribes. His descendants founded the Yuan dynasty in China, and in the W., after crushing the califs of Bagdad and the Seljuks (q. v.) of Iconium, conquered Moscow, and invaded Poland and Silesia (1241), but were forced by the united armies of Germany, Poland, and Silesia to retire into Moravia and Hungary. In 1243 they withdrew to Karakorum, between the rivers Onon and Tamir, there to elect a new Khan. Their empire at this period stretched from China to Poland, from India to Siberia; but, vast and unwieldy, it was doomed to a speedy decay. Expelled from China (1360), the M. rallied once more in Central Asia under Timur (q. v.), but in 1468 his empire too fell by its own weight; and in Jagatai alone, extending from the Sea of Aral to the Hindu Kush, was a Mongolian dynasty able to maintain itself. Hence came Baber (q. v.), who conquered India, and founded the Mogul (q. v.) line. At present the M. are mostly subject to those nations whom they once subdued—the Czar of Russia, the Sultan of Turkey, and the Tungusic sovereign of China. See D'Ohsson's *Histoire des M.* (4 vols. Amst. 1834–35); Max Müller's *Science of Language* (2 vols. Lond. 1862); and Henry H. Howorth's *History of the M. from the 9th to the 19th c.* (1 vol. Lond. 1876).

Moniteur, Le, formerly the official French journal, dates under the title of *Gazette Nationale*, or *Le Moniteur Universel*, from May 5, 1789. Since 1811 it has been known simply as *Le Moniteur Universel*. It was founded by Joseph Panckoucke, and after his death passed into the hands of his daughter, Madame Agasse. Always a docile instrument in the hands of the party in power, it has been republican, imperialist, and royalist in turns. Its editors often held high official rank, and its contributors on art, science, and literature numbered for many years the most brilliant writers of the nation. Under Napoleon III. it ceased to be a private property. On January 1, 1869, it was superseded by the *Journal Officiel* as the Government organ, and it has been conducted independently since, although during the siege of Paris it was selected by the Government of Defence for their official publications. At present (1877) it unofficially supports the Government of Marshal MacMahon. A reprint of its earlier numbers, published by Leonard Gallois in 32 vols. (1840, &c.), forms a most complete and interesting record of the great events of the first Revolution.

Mon'itor (Lat. 'a warner'), a name given to a genus of Lizards (q. v.), representing the family *Varanide*, in which the tongue is slender, bifid or cleft, and protrusible, and the body covered with scales. The head is long, and the tail keeled or ridged on its upper surface. The feet are well developed, and have toes furnished with strong claws. The M. inhabits the Old World, with the exception of one species, found in Mexico. The *M. Niloticus* of N. Africa is a familiar example. It may attain a length of 6 feet, and is said to devour the eggs of crocodiles. The name is derived from the animal's emitting a whistling sound, supposed to warn the observer of the approach of the crocodile. It is found most frequently in the neighbourhood of rivers. Representations of the M. occur upon the monuments of the ancient Egyptians.

Monito'rial or Mu'tual Instruction System, consisted in the employment of selected pupils as the teachers of their schoolfellows, under the superintendence of a head-master. It was first applied to solve the problem of popular education in England by Bell and Lancaster (q. v.) early in this century; and from its cheapness and the readiness with which it could be set in operation was extensively adopted. Its inherent defects, however, led to its speedy disuse, and it has been entirely supplanted in the public schools of Great Britain by the pupil-teacher system, established by the Committee of Privy Council for Education. See Pillans' *Rationale of Discipline*; Wood's *Sessional School*; Bell's *Madras School*; *British School Manual*; Currie's *Common School Education*.

Monk. See MONACHISM.

Monk, George, Duke of Albemarle, the second son of Sir Thomas M. of Potheridge, was born at Merton, near Torrington, in Devonshire, December 6, 1608. He took part in the descent on Cadiz (1625), and in the expedition to the Isle of Rhé (1627), and next served for ten years in the Dutch army under Lords Oxford and Goring. Returning to England on the eve of the Civil War, he attended Charles I. to Scotland (1639) as lieutenant-colonel in Lord Newport's regiment, and in 1642 passed over to Ireland with Leicester and Ormond to quell the revolt in Ulster. Recalled and arrested on suspicion of favouring the Parliament (1643), but soon released, M. rejoined his troops at Nantwich, where, in January 1644, he was defeated by Fairfax, made prisoner, and sent to the Tower. Three years' captivity and the persuasions of his kinsman Lord Lisle induced him to enter the parliamentary service (1646), and he was once more despatched to Ireland, where a treaty concluded with O'Neill brought him under the temporary displeasure of Cromwell. He accompanied that general, however, on his Scotch campaign, fought with distinction at Dunbar (1650), and was left with 7000 men to accomplish the subjection of the Highlands. This he achieved by four months' hard fighting, and in 1653 was joined with Blake and Dean in the command at sea, where he won two signal victories over the Dutch. A peace was concluded (1654), and M. resumed the command of the forces in Scotland, living for five years quietly at Dalkeith, and busying himself with gardening, but always regarded with a jealous eye by Cromwell, who in one letter charges him openly with plotting for the re-establishment of monarchy. Only with the Protector's death was the moment for action come. Rejecting Richard Cromwell's offer of £20,000 a year, M. gathered a convention at Edinburgh, levied money and recruits, and marched on London, the cry of a 'Free Parliament' preceding him like wildfire. He entered unopposed, and even while organising the Convention Parliament, opened negotiations with the exiled court. Charles, on his landing at Dover (May 23, 1660), embraced M., called him 'father,' and shortly after created him Earl of Torrington, Duke of Albemarle, a Knight of the Garter, and a Privy Councillor. He presided at the Admiralty (1664), governed London during the great plague (1665), and with Prince Rupert defeated the Dutch fleet in a three days' fight (1666). He died January 3, 1670, and was buried in Westminster Abbey. A far-seeing politician and an able and popular general, M. had a happy knack of taking the tide of affairs at its flood. His action in the Restoration is explained by his abandonment of the royalist cause at a time when it seemed desperate; and though a man of no greatness, he possessed the shrewdness and power of striking on the hot iron that render a man capable of great results. See Skinner's and Guizot's *Lives of M.*; Evelyn's and Pepys' *Memoirs*; Hallam's *Constitutional History*; and Macaulay's *History of England*.

Monk-Bird (*Tropidorhynchus corniculatus*), a species of Insectores, belonging to the Tenuirostral section of the order. It receives its name from its bare head resembling the shaven crown of a monk. The M.-B. is a native of S. Australia, where it is also named the 'Friar Bird,' 'Leatherhead,' and 'Poor Soldier.' The bill is elevated at the base, and the fourth and fifth quills are longest. The tail is long and rounded. The feet and claws are very strong. The bird feeds on the nectar of flowers, and also on insects. Its voice is powerful, but somewhat harsh. The wings are short, and the flight proportionally weak. The general colour is a greyish-brown, the tip of the tail being white. Long white feathers decorate the breast, and the under parts are light brown.

Monkey, the general name applied to the members of the mammalian order *Quadrumana* ('four-handed'), this latter division being included in the larger order of the *Primates*, in which Man (q. v.) is also ranked. The term 'Ape' is now limited to denote the more man-like of the *Quadrumana*—such as the Gibbon, Orang, Gorilla, and Chimpanzee, while the Baboon is by some authorities also styled an 'Ape,' although it is of a decidedly lower type than the four genera first mentioned. The lowest *Quadrumana* are the Lemur, Aye-aye, &c., which exhibit so many peculiarities and evidences of lower structure when compared with other *Quadrumana*, that they are by many authors included in the division *Prosimia* or Lower *Quadrumana*. Thus the term 'M.' may most significantly and properly be applied to the great bulk of *Quadrumana*, which typically represent the order, and which are intermediate in position between the lemurs on the one hand and the anthropoid or man-like apes on the other. A readily appreciated definition of a M. would be that of a higher mammal having a discoid or deciduate placenta, the *hallux* or great toe being usually opposable to the other digits, and the *pollex* or thumb also generally opposable to the other toes—so as to convert both feet and hands into prehensile organs. The incisor teeth generally number four, and the molars six in each jaw. Perfect collar-bones or *clavicles* are developed, and the mammary glands are *pectoral*, i. e., placed on the breast. Monkeys are divided into 3 well-marked groups. Of these the (1) *Strepsirrhina* have curved or twisted nostrils, situated at the extremity of the snout. As a rule the incisor teeth number six in each jaw, those of the lower jaw being aslant. Tuberculate molars occur. The second toe has a claw-like nail; all the feet have five toes, and the thumbs are opposable. To this group belong the Aye-aye or *Cheiromys*, the Lemur, and Loris, the Strepsirrhine Monkeys being confined for the most part to Madagascar, and some few species inhabiting the E. Archipelago. The (2) *Platyrrhina* Monkeys inhabit the New World exclusively, and are represented by the Spider M. (*Ateles*), Howling M. (*Myocetes*), Marmoset, Squirrel M. (*Callicebus*), &c. In these the nostrils are broad and widely separated. The tail is prehensile, and the premolar teeth number six in each jaw. No cheek pouches or natal callosities exist; and the thumbs are either wanting, or if present are but feebly opposable. The (3) *Catarrhina*, or Old World Monkeys, have thirty-two teeth, arranged as in man. In one genus (*Colobus*) only are the thumbs wanting, the thumbs and great toes being opposable. The canine teeth are large and projecting, and cheek pouches and natal callosities are frequently found. The tail is long, and never prehensile. Cheek-pouches and callosities exist in such Catarrhine Monkeys as the *Semnopithecus* of India, the Guenons, Macaques, &c. In the baboon and mandrill the tail is short and the muzzle is long; while in the anthropoid ape or man-like monkey the tail and cheek-pouches are wanting, and natal callosities are generally absent.

Monkey-Pot, the popular name given to the fruit of *Lecythis Grandiflora*, a Brazilian species belonging to the natural order Myrtaceæ, tribe Lecythidaceæ (q. v.). The capsule, containing eatable almond-like fruits, resembles in general shape an S-shaped urn, 5 inches long by 3 broad, closed at its upper end by a lid which fits into a circular opening nearly 2 inches in diameter.

Monk's-Hood. See ACONITE.

Monk's-Rhubarb. See DOCK.

Monkwearmouth. See SUNDERLAND.

Monmouth, the county town of Monmouthshire, England, finely situated at the confluence of the Monnow and Wye, 18½ miles W.N.W. of London by the Great Western Railway. Its famous castle, of which only a fragment remains, was the favourite residence of John of Gaunt, and the birthplace of Henry V., hence called 'Harry of M.' The church of St. Mary, with its beautiful spire, in part dates from the 14th c. M. has iron and tinplate works, corn-mills, and tanneries, besides wood-turning and paper-making industries, and a trade on the Wye in bark, timber, and country produce. With Newport and Usk, it sends a member to Parliament. Pop. (1871) 5879.

Monmouth, James, Duke of, son of Charles II., by Lucy Walters, was born at Rotterdam, 20th April 1649, entrusted to the care of Lord Crofts, whose name he took, brought up as a nobleman by Henrietta Maria, and made his appearance at

Whitehall, 1662. Pepys writes in his *Diary* for September 7th, of that year, 'Here I also saw Madam Castlemaine, and which pleased me most, young Crofts, the king's bastard, a most pretty sparke of about fifteen years old.' In his sixteenth year he received the title of Duke of Monmouth, and married Anne, daughter of the Earl of Buccleuch, who brought him a fortune of ten thousand a year. He took her name, and became Duke of Buccleuch in Scotland, a Knight of the Garter, Master of the Horse, Commander of the first troop of Life Guards, Chief Justice of Eyre, S. of Trent, and Chancellor of the University of Cambridge. In 1673 M. led the English auxiliaries against the Dutch, and earned a high reputation for courage and military skill. On his return from the Low Countries he was received by the people of London with royal honours, and the story began to be bruited abroad that he was the legitimate son of the king. Though the king made a solemn asseveration before his Council to the contrary, the rumour was credited, and the Duke of York had to retire from England. By his clemency at the battle of Bothwell Bridge, M. won (1679) still more the affection of the Protestant party. Acting under the advice of the Earl of Shaftesbury, he made what were really a series of royal progresses throughout England, bore on his escutcheon the English lions and French lilies without the baton sinister, mixed in rustic sports, acted as godfather to the children of the peasantry, and touched for king's evil. The popular enthusiasm ran so high that Charles compelled M. to retire to Holland, while the Duke of York was recalled to the court. But in 1680 M. was again permitted to return, and again he courted the favour of the people by royal progresses. Being apprehended at Stafford, he made his escape to Antwerp (1684), where he became the centre of a host of intriguing exiles. After the king's death he planned an invasion—the Earl of Argyll to land in Scotland and promote his cause there, whilst he was to set up his own banner in the S. of England. M. disembarked in Dorsetshire (21st June 1685), published a violent manifesto against James II., gathered round him crowds of farmers and traders, but failed to attract the nobles and gentry. Advancing through Taunton and Frome, M., though he had meanwhile heard of the failure of the Scotch expedition, rashly attacked the king's troops at Sedgemoor (July 5th), and suffered a miserable defeat and capture. James had no mercy on him, though M. appealed in most humiliating terms for pardon. He was executed at London, 25th July 1685. M. was a confirmed libertine, but his accidental attachment to Protestantism secured him popular esteem. The attractive boldness of his character, and his charm of manner, were not, however, supplemented by the stronger virtues necessary for permanent distinction. See Robert's *Life, Progresses, and Rebellion of James, Duke of M.* (Lond. 2 vols. 1844); Macaulay's *History of England* (vols. i. and ii.); and Green's *Short History of the English People* (1875).

Monmouthshire, a county in the W. of England, is bounded W. and N.W. by the Welsh counties of Glamorgan and Brecknock, N. and N.E. by Hereford, E. by Gloucester, and S. by the Severn's estuary. Area, 368,399 statute acres; pop. (1871) 195,448. The northern part of M. is mountainous, and celebrated for its scenery. The highest points are the Cradle, 2645 feet, and the Sugar-Loaf, 1856 feet. The chief rivers are the Usk and the Wye, the latter of which partly confines the county on the W. Bordered by the Caldeco, and Wentloog Levels, the coast, 22 miles long, is low-lying, and protected by extensive sea-walls. M., in part formed of Old Red Sandstone, and of the S. Welsh carboniferous measures, is particularly rich in coal, ironstone, and limestone. In 1876 there were 37,473 acres under corn crops, 13,674 under green crops, 23,486 in clover, sanfoin, and grasses, and 152,236 in permanent pasture, exclusive of mountain and heath; and M. had 10,597 horses, 42,222 cattle, 194,455 sheep, and 14,714 pigs. The chief crops are wheat, barley, oats, turnips, and swedes. Grazing and farming are the general occupations, but in the W. part the dominant industries are the mining of coal and iron, and the iron manufacture. The towns are Monmouth, Newport, Chepstow, Rhymney, Pontypool, Tredegar, and Abergavenny. M. is a centre of antiquarian interest, and among its many ruined piles are Caldecot (pron. Calcot), Raglan and White Castles, and the abbeys of Tintern and Llanthony.

Monochlamydeæ, or **Apetalæ**, the fourth sub-class of the Dicotyledons (q. v.), embracing those plants whose flowers have a calyx only or no perianth. It is subdivided into (a)

Angiosperma, in which the ovules are in a pericarp, to which Polygonaceæ, Lauraceæ, Euphorbiaceæ, and Amentiferae belong; and (b) *Gymnosperma*, in which there is no pericarp, as in the Coniferae and Cycadaceæ.

Mon'ochord (Gr. *monos*, 'single,' and *chordē*, 'a string'), an instrument formed by a board with bridges at both ends, between which a string is distended, used for experiments on the vibrations of strings, and for ascertaining the relative proportions of musical sounds. It was known to the ancients, and is said to have been invented by Pythagoras. The name is also given to an old instrument of the Clavichord kind, which should be more correctly called monichord.

Monocotyledonous Plants form one of the primary classes in the natural system of botany, comprising those plants in which the embryo has only a single cotyledon, the vascular bundles of the stem are dispersed through the cellular tissue, and the prevalent number of the parts of the flower is three or six. The leaves are usually parallel-veined. This great class may be conveniently separated into three divisions:—1. Those with glumaceous flowers, including grasses and grass-like herbs, such as sedges; 2. Those with petaloid flowers and ovary inferior, as in the orchis, the iris, the agave, &c.; 3. The flower petaloid, ovary superior, as in the palms, the lilies, the arums, &c. The great systematist, Mr. Bentham, in a paper recently laid before the Linnæan Society, propounds an arrangement into four series, viz., *Epigynæ*, *Coronariæ*, *Nudifloræ*, *Glumales*. The term *Endogens*, as found in botanical books, is synonymous with M. P.

Monodel'phia (Gr. *monos*, 'single,' and *dolphus*, 'the womb'), De Blainville's name for the highest division of mammalia (including all the higher mammals and man), in which the two oviducts or *Fallopian tubes* coalesce to form a single *uterus* or womb, which may, however, exhibit at its *fundus* or base a partial separation into two halves. The so-called 'cornua' or 'horns' of the uterus in the horse, &c., exemplify this condition, and attest the formation of the uterus as a double organ, or from a union of the Fallopian tubes. In M. the uterus opens into a single *vagina* or outlet, which is completely separated from the bowel or *rectum*. All M. have a *placenta*, and hence this division of the mammalia corresponds with that of the placentalia.

Mon'odon. See NARWHAL.

Monœ'cious (Gr. *monos*, 'single,' and *oikion*, 'a dwelling') is a term used in botany to imply that male and female organs in different flowers are borne on one and the same individual plant. Familiar examples are the oak, birch, beech, and hazel, where the catkins are the male flowers, and the female are much less conspicuous. The cucumber being a M. plant, gardeners often effect artificial fecundation. See DIOECIOUS and HERMAPHRODITE.

Mon'ogram (Gr. *monos*, 'single,' and *gramma*, 'a letter') is a device or figure formed by interlacing two or more letters which are the chief components of a name or title of a person or place. The use of monograms is very ancient, dating from the time of Philip of Macedonia; while in the ancient records of India and China they are common. The study of monograms is specially interesting historically; since upon a knowledge of them depends the true understanding of many inscriptions and monuments. See Heller's *Monogrammen-Lexikon* (1831), Bruillot's *Dictionnaire des Monogrammes* (3 vols. 1832-34), and Nagler's *Die Monogrammisten* (4 vols. 1857-70).

Mon'ograph (Gr. *monos*, 'single,' and *graphē*, 'a writing'), is the name given to a paper or memoir which deals exclusively with one particular topic. It was originally restricted to a scientific memoir, but is now applied to any historic, literary, or theological paper which undertakes to deal exhaustively with a special subject.

Mon'olith (Gr. *monos*, 'single,' and *lithos*, 'a stone'), is a pillar or anything cut from a single block of stone. Remarkable examples are found in Egypt, and several European cities boast of Monolithic columns removed from that country. See OBELISK.

Monoma'nia (Gr. *monos*, 'single,' and *mania*, 'madness') is the term applied, by some physicians, to that form of insanity in which the mind of the patient is absorbed by one idea, or is irrational on one subject only. There is great dis-

parity of opinion among psychologists regarding the proper use of the term. With one author, M. means only a fixed morbid idea; with another, only partial exaltation; while a third restricts it to a single morbid impulse. Examples of M. may occur under the form of delusional insanity, or those states in which marked delusion is present, whether of a melancholic or exalted character, the former condition being termed melancholia with delusion, and the latter M. with delusion; or of a destructive character, homicidal and suicidal insanity, &c., with delusion; or under the form of emotional insanity, or morbid state of the emotions without delusions, the affective M. of Esquirol. This form of insanity may be marked by a perverted moral sense, or by impulses of a destructive character without delusion. The species or varieties of M. must correspond to the faculties of the mind, and to their combinations; so that we have intellectual, emotional, and volitional monomanias, as also mixed forms; and each variety may be marked by exaltation or depression. M. may be simple or complex, stationary or progressive; thus monomanias may be sound on all points except one, or the M. may be associated with more or less general incoherence. As a general rule, even in apparently simple cases, other faculties are implicated, so that persons suffering from M. cannot be regarded as responsible for their actions. In some cases, however, it is impossible to say where sanity terminates and insanity begins. There are many varieties of M., and in all cases they are to be regarded with suspicion as the first symptoms of general insanity. The more marked forms of M. are those characterised by a particular delusion, such as that the person is made of glass. According to Pritchard, M., or partial insanity, is characterised by some particular illusion or erroneous conviction impressed upon the understanding, and giving rise to a partial aberration of judgment. The individual affected is rendered incapable of thinking correctly on subjects connected with the particular illusion; while in other respects he betrays no palpable disorder of the mind. When there is no morbid perception, but only a false conception, French writers employ the expressions *conception fautive*, *conviction délirante*, *idée fixe*. The chief varieties of M. are M. of Suspicion, of Fear, of Superstition and unseen agencies, of Vanity or Euphoria, of Pride and Ambition, of Religion, as also Erotomania, Kleptomania, and Dipsomania. See *Psychological Medicine*, by Drs. Bucknill and Tuke (Lond. 1874).

Monongahela, a river of the United States, rises in the Alleghanies in the W. of Virginia, flows N. into Pennsylvania, and at Pittsburg joins the Alleghany to form the Ohio, after a sinuous course of 300 miles in a rich mineral and timber yielding country. It is navigable to keel boats for 200 miles.

Monoph'ysites (Gr. *monos*, 'single,' and *physis*, 'nature') are those who have maintained that the divine and human natures in Jesus Christ are so united as to form but one nature, which is partly divine and partly human. This heresy originated with Eutyches (q. v.), who taught that by the union of the divine and the human nature in Christ the latter was extinguished, so that the Glorified Saviour is wholly divine. The modification of this doctrine which was adopted by the M., was due to Dioscorus, Patriarch of Alexandria, who presided over the 'Synod of Robbers' at Ephesus (449). Dioscorus was deposed by the Synod of Chalcedon (451), which condemned Eutyches; but the patriarch elected in his stead was murdered, and the patriarchate of Alexandria remained in the hands of the M., with brief interruptions till the 8th c. So strong had the sect become by 476, that in that year the Emperor Basiliscus was persuaded to publish an edict renouncing the Synod of Chalcedon altogether, in which he was supported by the Patriarchs of Cæsarea, Jerusalem, and Antioch, and about 500 bishops. About the middle of the 6th c. it was much depressed, owing to the persecution by the orthodox party, and internal dissensions; but a revival took place in Syria, Mesopotamia, and Egypt, under Jacobus Baradaeus (541-578), and originated the Jacobites (q. v.). Besides the Jacobites, the M. at the present day include the Copts (q. v.), the Maronites (q. v.), and the Armenians (q. v.).

Monop'oli (Gr. 'the solitary city'), a seaport of Italy, province of Bari, on the Adriatic coast, 25 miles S.E. of the city of Bari by rail. It is the seat of an archbishop, and is situated in a rich olive district. Near it are some fine rock-hewn tombs, whose contents are preserved in the Bari museum. Pop. (1874) 13,800.

Monopoly (Gr. *monos*, 'sole' and *pólis*, 'sale'), as used in Aristotle's Politics (l. 11), means simply the operation, known in Scotch law as forestalling and regrating, and in English law as engrossing, of one man buying up the whole supply of a commodity to sell it at his own price. Such an offender was in Roman law called a *Dardanarius*, and punished under the *Lex Julia de Annona* (D. 48, 2, 2). M. of clothing, fish, and all other articles of food was prohibited by the Emperor Zeno (Code iv. 59), under pain of confiscation and exile. The matter is also mentioned in a previous constitution of Leo in the year 473; there seems to have been a corrupt practice among the Imperial Magistrates of obtaining authority for this illegal traffic. At Athens a law limited the amount of corn a man might buy. The definition of the old Scotch offence seems to have been borrowed in 1592 (c. 150) from an English statute, which did not apply to retail dealers, 6 Edw. VI. c. 14. Forestalling consists in the buying or contracting for any commodity on the way to market, or dissuading any one from carrying his commodity to market, or making motion to enhance the prices in the market. The regrator, again, was he who bought victual, flesh, fish, or other wares in fair and market, and sold them again either in the same or in any other fair or market within four miles, or who, by buying, contract or promise, gets into his hand the corn growing in the field. At the end of the 16th c. heavy fines were imposed in a few such cases where cattle and corn 'had been kept up to a dearth.' In one case a conviction followed on the charge against a *merchant* of buying corn in order to sell it again, it being said that this was unlawful except for maltsters and dealers in meal. So late as 1607 a Leith merchant was convicted of buying a ship-load of timber in the harbour before landing or entry in the town's books. These laws belong to a period when the privilege of buying and selling certain commodities was often given by the Crown or superior to a certain community to be exercised in a certain place, often at prices to be fixed. In English law every grant by the Crown of the sole right of buying, selling, making, using, &c., was bad if it raised the price, deteriorated the article, or impoverished artificers. But the Crown had the power, much abused by Elizabeth, of creating by letters-patent the exclusive privilege of buying and selling, where the grant was of general use, or where an individual had brought something new or useful into the country. This led to the great statute of monopolies, 21 Jas. I. c. 3, which restricted monopolies in favour of the true inventors to fourteen years, provided the M. was not mischievous to the state nor generally inconvenient (see PATENT). Patents and copyrights are thus not monopolies in a legal sense of the word; they are statutory rights of property. The old M. implied a right to tax the public to any extent which would not make them forego the use of the commodity. Limitation of competition, even where it merely excludes foreign production, is in every case bad. A patent merely postpones a part of the increased cheapness which the public owe to the inventor. The word M. is still applied to cases where, from the conditions of trade, certain persons possess exclusive natural advantages. Small capitalists cannot enter certain trades with hopes of success; the local situation of one great industry near another on which it depends is another example. Great hardship on the one hand, and great meanness on the other, have often accompanied combinations to buy up, especially in times of scarcity. But it is impossible to suggest any legal limit for the general market: it is only in a small department, like the Stock Exchange, that it may be possible to introduce some wholesome rule against the mere speculation in prices.

Monostoma, or **Monostomum** (Gr. *monos*, 'single,' and *stoma*, 'mouth'), a genus of *Trematode* worms or flukes, having a single sucker only, in which the mouth opens. In their perfect state they exist as parasites in water-fowl, their miniature or embryonic forms being found within freshwater mollusca, such as the *Planorbis* or pond snail. *M. lentis*, a familiar species, has been known to occur within the lens of the human eye in a case of cataract.

Monothelism (Gr. *monos*, 'one,' and *theos*, 'God'), means the belief that there is but one God, as opposed to Polytheism (q. v.), or Dualism (q. v.). This Supreme Being, however, is conceived in several ways: in *one form*, as the Jehovah of the Hebrews and the Allah of the Mohammedans; in *three forms*,

as the Trinity of Christians; or in *all forms*, as the Infinite of the Pantheists.

Monothelism (Gr. *monos*, 'one,' and *thelma*, 'will') was a heresy which arose in the Church in the 7th c. as a development of the teaching of Eutyches (q. v.), with which it was almost identical, its distinctive doctrine being that in consequence of the union of the divine and the human natures in Christ he had only one will, the divine, which governed all his actions, both divine and human. This theory is said to have originated with Theodore, Bishop of Pharan, in Arabia, and was adopted by the Patriarchs of Constantinople and Alexandria as a likely foundation for a compromise between the Monophysites (q. v.) and the Orthodox, and in this light it was laid by the latter before the Emperor Heraclius, who received it with enthusiasm. But the doctrine was condemned by a Lateran Council (649), and afterwards by the Council of Constantinople (680).

Monotremata (Gr. *monos*, 'single,' and *trēma*, an 'opening'), the lowest order of Mammalia, represented by the *Ornithorhynchus* (q. v.) or 'duck-billed water mole' of Australia, and by two species of *Echidna*—the porcupine ant-eaters of the same region. The name M. is derived from the urinary, generative, and digestive systems opening into a common cavity or *cloaca*, which in turn opens on the surface of the body by a single aperture. This disposition of parts is eminently bird-like, and even more so is the form and arrangement of the female reproductive organs. The two oviducts or 'Fallopian tubes' in M. remain separated throughout their entire extent, each dilating to form a uterine cavity which opens into the cloaca. So bird-like is this arrangement that the name *Ornithodelphia* was given by De Blainville to the division of Mammalia of which the M. is the only representative order. Further characters of M. are that (as in birds) the bones of the skull become firmly united together, so as to obliterate the *sutures* or lines of union; that the jaws want teeth, and in the *Ornithorhynchus* are covered with horny plates, so that the animal appears to be furnished with a bill, resembling that of a duck in shape; that the *coracoid bones* are developed separately from the *scapula* or shoulder-blade, as in birds; and that these bones extend to the breast-bone, while the clavicles also are united as in birds. Marsupial bones, similar to those found in Marsupialia (q. v.), exist in M., but these structures never support a pouch or *marsupium* in the present order. The testes of the male M. are retained throughout life within the abdomen. No outer ears are developed, and the mammae are unprovided with nipples. The brain-structure of M. is decidedly bird-like. The *corpus callosum* is small, and by Owen is believed to be absent altogether. The feet have five toes each, and the males have a *tarsal spur*. No *placenta* is developed, and the angle of the lower jaw is not inflected.

Monotropaceæ is now from structural affinities generally considered a sub-order of *Ericaceæ*. The plants, however, comprised in it are very exceptional in appearance, all having the aspect of parasites, and their leaves are reduced to scales. In Britain the group is represented by *Monotropa Hypopitys*, found growing among decaying organic material in connection with the roots of fir, beech, and willow.

Monreale, a town in Sicily, province of Palermo, on the Monte Caperto, near the river Oreto, 4½ miles W.S.W. of Palermo. It is the seat of an archbishop, and has a magnificent cathedral (dating from the 12th c., and restored since the fire of 1811), held to be the finest specimen of the Sicilian Norman style, and built in the form of a Latin cross, 333 feet long and 131 wide, with bronze doors (1186). Eighteen granite pillars support the pointed vaulting of the nave, which is in the Arabian style, and the walls (70,400 sq. feet) are covered with the richest mosaics. M. has also a rich Benedictine monastery (1174), with beautiful cloisters. On the road from Palermo to M. began (30th March 1282) the massacre known as the Sicilian Vespers. Pop. (1874) 16,211.

Monro, Alexander, *primus*, a celebrated Scotch anatomist, son of a physician, and grandson of Sir Alexander Monro of Bearcrofts, was born in London, September 8, 1697, and educated at London, Paris, and Leyden. He was appointed lecturer of anatomy to the Surgeon's Company at Edinburgh in 1719, and delivered a course of lectures on that subject in 1720.

The great Medical School of the University of Edinburgh dates from his appointment as Professor of Anatomy in 1721. He was a brilliant lecturer and successful demonstrator. His father was one of the founders of the Royal Infirmary, and on its opening M. became physician to the institution. He was secretary to the society afterwards known as the Philosophical Society, and was a large contributor to the six volumes of *Medical Essays* which it published in 1732. M. died July 10, 1767. His works include *Treatise on Osteology* (1726), *Observations Anatomical and Physiological* (1758), and an *Account of the Success of Inoculation of Small-pox in Scotland* (1765). Memoirs of M. were written by his son Donald, a physician and medical writer, born 1731, died 1802.—A. M., *secundus*, youngest son of the preceding, born March 24, 1733, at Edinburgh, educated there and at Berlin, succeeded his father as Professor of Anatomy in 1760, a position he held for forty-eight years, and also as Secretary to the Philosophical (afterwards the Royal) Society, to whose Transactions he contributed. He died October 2, 1817. Among M.'s works may be noticed his treatises *On the Structure and Functions of the Nervous System* (1783), *A Description of the Bursæ Mucosæ of the Human Body* (1788), *The Structure and Physiology of Fishes* (1785), and *Three Treatises on the Brain, the Eye, and the Ear* (1797).—A. M., *tertius*, son of the preceding, born in Edinburgh, November 5, 1773, succeeded his father in the Chair of Anatomy in 1808, having been joint-professor for ten years previously. He retired in 1847, and died at Craiglockhart, near Edinburgh, 10th March 1859. The three Monroes had thus been connected with the University of Edinburgh for more than 120 years. M. *tertius* contributed to the *Transactions of the Royal Society*, and was author of *Outlines of the Anatomy of the Human Body* (4 vols. 1813), and other works.

Monroe, capital of M. county, Michigan, U.S., near the entrance of the Raisin into Lake Erie, 35 miles S. of Detroit by rail. It has large flour and saw mills, and manufactures of tobacco and machinery. Near it are extensive vineyards. Pop. (1870) 5806.

Monroe, James, fifth President of the United States, was born, of an old Cavalier family, in Virginia, April 28, 1758. He fought with distinction in the revolutionary war, and at its close studied law, and became a member of the legislature of Virginia. Elected to Congress in 1783, he was one of the delegates appointed to frame the Constitution of the United States. Sent as United States Minister to Paris in 1794, he was recalled within a year on account of his democratic enthusiasm. In 1799 M. was elected Governor of Virginia, and under Jefferson's Presidency was successively envoy to France (1802) and minister at London (1803-8). In the former capital he negotiated the purchase of Louisiana for his Government for fifteen million dollars. He was Secretary of State from 1811 to 1817, when he was elected President, being re-elected in 1820. Under his Presidency the United States acquired Florida. He died at New York, 4th July 1831. Without shining talents, M. was a prudent, energetic, and successful administrator. His policy aimed at the peaceful development of the great resources of his country, but he was also propounder of the famous 'M. doctrine,' that no European power had a right to interfere in the affairs of America, and that the introduction of their system to any part thereof would be dangerous to the United States. See John Quincy Adams' *Lives of J. Madison and J. M.* (Rochester, U.S., 1850).

Monro'via. See LIBERIA.

Mons (Fr.; Flem. *Berghen*: both names mean 'hill town'), the capital of Hainault, Belgium, on the Trouille, 16 miles N. of the French frontier, and 40 S.W. of Brussels by rail. Its fortifications were demolished in 1866, but it can still be defended by flooding the vicinity with the waters of the Trouille. The chief buildings are the beautiful Gothic cathedral of St. Waudru, founded in 1450, and an interesting town-house built in 1443. The castle is now used as an asylum. Lying in the heart of a great mining centre, M. has an active trade in coal, and is an important railway junction. A canal (*le Canal de Conde*) connects the town with the Scheldt. It also trades in horses, cattle, flax, hemp, &c., and manufactures woollens, cottons, linens, lace, pottery, tobacco, and cutlery. Pop. (1875) 24,539. It suffered much during the wars of the 17th and 18th centuries.

Monse'lice (the *Mons Silicis*, 'Flint Mountain,' of the Lombards), a town of Italy, in the province of Padua, 27 miles N.N.E. of Ferrara by rail, with silk-mills, a ruined castle, and dismantled walls. Pop. (1874) 9765.

Monsoon (derived from the Arabic word *mausim*, 'a regular season'), the name applied to the periodical winds which prevail in the Indian Ocean, and directly determine the climate and rainfall throughout the peninsula of India. Like the Trade Winds Proper (q. v.), of which they are really only a modified continuation, their existence is due to the unequal distribution of earth and water on the surface of the globe in the neighbourhood of the equator, which, combined with the rotation of the globe, causes regular interchanges of currents of hot and cold air. The S.W. M., which, roughly speaking, blows from April to October, brings its annual rainfall to the Malabar or E. coast of India, and ultimately to Bengal and Hindustan Proper. A reverse current from the N. E. prevails during the remaining months of the year, on which depend the winter rains of Upper India, and the one rainy season of the Coromandel or W. coast. The changes of the season, or breaking of the M., are usually ushered in by variable gales and thunderstorms.

Mon'ster, Monstros'ity, terms applied in physiology and anatomy to describe any organism which departs in an extreme and marked degree from the type of structure of its kind. The science of *Teratology* is that which undertakes the description of such organisms, and which endeavours to trace the lines of their deviations. Tales of beings half-brute and half-human are common enough among the early legends of our own and other countries; and even as late as the 16th c. we find Rueff and Schotus discussing the probability of monsters being produced through the sexual union of women with devils. The causes of monstrosity have been referred in our own day, and are still so referred by many persons, to the influence upon the unborn progeny of some impression made on the mind of the mother. A parturient woman, after seeing the stump of an arm which has undergone amputation, bears a child which wants an arm. Another is startled by a frog, and bears a child whose countenance is frog-like. Such instances might be multiplied without end. The *post hoc* in such cases, of course, is accounted for on the principle of *ergo propter hoc*, and the result being first found is naturally and easily referred to some cause. Admitting to the full the influence upon and connection of the mother with the foetus, cases of monstrosity are not to be explained on such grounds as those on which the popular belief is founded. It frequently occurs, indeed, that a woman who has borne a first malformed child, and who fears for a like result in her second pregnancy, bears the second child in a perfectly hale and normal condition. Yet in such a case, if mental influence is to count for anything in producing malformation, one should certainly expect the second child to exhibit even a greater departure from the normal type than the first. Monsters are produced by no chance rules, but by the infringement of some law or laws; the malformation itself following a law of its own in the course of its production. What are popularly named 'freaks of nature' have no existence in fact—so-called 'freaks' simply representing the action of a law of abnormal growth in counterbalancing the law of healthy development.

Monsters exhibit certain well-defined groups or classes which are defined according to the nature and extent of the abnormality. Thus one prominent group consists of monsters, in which parts which are normally present, exist in a small, or atrophied condition, or may be altogether wanting. *Accephali* or headless foetuses, and *anencephalous* or brainless monsters, are by no means uncommon, and illustrate this first group. Parts which are normally united may be unconnected—as when the walls of the chest or abdomen are imperfectly developed—and those instances in which such conditions occur exemplify a second class of cases of monstrosity. Union of normally free parts forms a third description of abnormalities, illustrated by the closure of the mouth, nostrils, or the union of internal organs. More typical, however, are the cases included under a fourth head—that of excessive development of parts and structures. This excess may proceed to the degree of producing portions or the whole of a second foetus attached to the body of the first and normal one. Such 'double monsters' are the best known of all. The duplicity may be *anterior*, where the bodies of the two individuals are united face to face; or *posterior*, where union occurs by the opposite surfaces.

In *lateral duplicity*, the union is for the most part anterior, but the bodies are to a great extent separable at the sides. Sometimes *inferior duplicity* also occurs, the bodies having separate heads, but being united to a greater or less extent by the trunks. Other groups of monstrosities present excessive developments of internal organs only—these resulting frequently from diseased action. *Triple* monsters are also known to occur both in man and in the lower animals, and it is also to be noted that monsters most frequently occur in those animals which have been domesticated by man. Malformations of the genital organs produce cases of *hermaphroditism*, real or supposed, but the laws which appear to regulate the production of the latter lesions are comparatively well ascertained. The 'Siamese Twins,' who died at a comparatively advanced age; the 'Double-Headed Nightingale,' two united negro-children; and the 'Hungarian Sisters,' are the most famous instances of human monstrosities.

Monstrosity in Botany.—Vegetable Pathology may be divided into Teratology or the study of malformation, and Nosology or the diseases of plants; it is, however, impossible to draw any sharp line of demarcation between the two, and often one cannot be conceived without the other. The causes of the phenomena are various. Atmospheric influence and the nature of the soil affect changes in the size, number, arrangement, and shape of the organs of a plant. Adhesion in growth produce much alteration in appearance, and in like manner the separation of organs normally united. Changes in form coming under the head of fasciation may be illustrated by the cauliflower and the cockscomb, and other changes arising from the metamorphosis of whole parts of plants, causing a variety of monstrous growths, come under Proliferation, Antholysis, and Gemmation. The attacks of parasites, and animal injuries, are also fruitful of vegetable monstrosities. See METAMORPHOSIS OF ORGANS.

Mon'strance (Lat. *monstrare*, 'to show') is a utensil used in Roman Catholic churches for holding the Host (q. v.) when it is exhibited to the people, either on the altar or in procession, consisting of a sun-shaped holder, in which the host is placed, fixed on a foot or stand. Being for such a sacred use, it is of course generally of the most costly materials and workmanship, and, like all the utensils used in the Eucharistic service, is consecrated.

Monstrelet, Enguerrand de, a French chronicler, was born about 1390, is supposed upon his own authority to have belonged to a noble family, was connected in 1430 with the court of Jean de Luxembourg, under whom he held some office until 1440. At Compiègne he saw Jeanne Darc, and witnessed the interview of the Duke of Burgundy with her. In 1444 he took the oath as Provost of Cambrai, and died 20th July 1453. M.'s fame rests upon his *Chronique*, a work composed of three books, two only of which are his. The first extends from 1400 to 1422, and the second carries on the narrative to 1444. The work, compared with the vivacious pages of Froissart, is inexpressibly dull, but its value as an accurate record of facts is quite as great. The best edition is that of M. D'Ouët D'Arcq (2 vols. Par. 1857-58).

Montagna'na, a town in N. Italy, province of Padua, 45 miles W.S.W. of Venice. It has an old citadel and walls, some woollen and linen weaving, and a trade in hemp and spun silk. Pop. (1874) 9178.

Montagnards were the members of the party called La Montagne (the Mountain), which played such a bloody part in the great French Revolution. They were so designated because they sat on the topmost benches in the National Convention. The power of the party was shattered by the fall of Robespierre in July 1794. The name has since been occasionally given to extreme Revolutionists, and was applied to a short-lived corps of urban militia organised in Paris after the Revolution of 1848.

Mon'tagu, Lady Mary Wortley, eldest daughter of Evelyn, Earl and afterwards Duke of Kingston, a pleasure-loving nobleman, was born in London in 1689. As a child she was famous for beauty and intelligence, and the pet of the Kit-Kat Club. Bishop Burnet assisted her in her Latin, and she was an insatiable reader. When in her teens she fell in love with Mr. E. Wortley M., a Whig M.P., but difficulties regarding the match intervened which were only solved by an elopement in 1712. On the accession of George I. Mr. M. was appointed

a Commissioner of the Treasury, and his lovely and accomplished wife shone as a resplendent meteor in circles of wit and fashion. In 1717 he was nominated Ambassador at Constantinople, whither Lady Mary accompanied him, and to this visit we owe those charming letters on Oriental life, which, though not published till after her death, have been the delight of posterity ever since. On her return to England in 1718 she advocated the introduction of inoculation, and at length her ardour and courage won the day against the faculty and public prejudice. About this time she published *Town Eclogues*, and her violent literary feud with Pope occurred. Satirised by her former admirer in the *Dunciad* and *Imitations of Horace*, she retorted vigorously in a retaliatory poem. In 1737 she left England, where her husband remained, and she resided principally at Lovero, Italy, till his death in 1761. She died in London, August 21, 1762. An edition of her letters in 3 vols. was published by the notorious Captain Cleland in 1763, and an additional volume (suspected to be a forgery) in 1767. A collection of her works was published in 1803 (2d ed. 1817). In 1837 Lord Wharnclyffe published her *Letters and Works* (3d ed., with memoir by W. Moy Thomas, 1861). Her letters depict with a certain lightsome grace and simplicity the manners and fashions of her time, and are full of lively feminine gossip. Those on Turkey are decidedly the best. See *Queens of Society* (Lond. 1860).—**Edward Wortley M.**, the erratic and profligate son of the preceding, was born in 1715. He sat in the House of Commons during two parliaments, and published *Reflections on the Rise and Fall of Ancient Republics* in 1739. He spent many years in the East, ultimately became a Mahometan, and died at Venice, 2d May 1776, while making preparations for a pilgrimage to Mecca. In Nichol's *Literary Anecdotes of the 18th Century* there is an interesting sketch of his career.

Montaigne', Michel Eyquem de, was born of a noble family at the Château de Montaigne, in Périgord, 28th February 1533, taught from the cradle to speak Latin, finished his studies at the Collège of Guyenne, entered upon a course of law at Bordeaux or Paris, and (1554) became Councillor in the Parliament of Bordeaux. Until 1568, when his father died, M. faithfully discharged his legal duties, but in 1570 resigned his office, and was appointed by Charles IX. chevalier of the Order of St. Michel. Though court life was distasteful to him, he accepted (1576) the post of Gentleman-Ordinary to the king, and later that of Gentleman of the Chambers to the King of Navarre. Meanwhile he had translated the *Natural Theology* of Raymundus Sebondus, and in 1580, after some years of retirement he gave to the world his *Essais* in two books. During the same year he set out upon a travelling tour through Italy, Switzerland, and Germany. An interesting journal of his travels, written partly in the most careless French and partly in ungrammatical Italian, still survives. He was recalled at the King's order to accept the mayoralty of Bordeaux, which had been conferred on him (1581). Having sustained the interests of the town so well before Henri III., he was re-elected for another term. In 1585 he prepared a new edition of his *Essais*, and three years later returned to his château, where he died 13th September 1592. M. is among the greatest of the French moralists. Anything like a systematic body of ethics is not to be found in his *Essais*. Their charm consists in a delightful frankness, garrulity, and egotism. His experiences were wide and various, his adoration of antiquity immense, his meditative insight as keen as it was profound. The result is that his *Essays* are full of life and movement, penetrated with appropriate learning, and coloured by the hues of a philosophy which drew none of its inspiration from the current religion. M. was a thorough man of the world, but he was temperate because he stood aside from party, wise because his thoughts were unhampered by tradition, and genial through natural bias. The *Essays* have another merit of a different kind. French critics note that they form an epoch in the history of the French language. A certain supple grace of expression—the result of M.'s classic studies—was infused by him into the national diction, and has ever since remained one of its chief distinctions. Among modern editions may be noticed those of Victor Leclerc (5 vols. 1826), Buchon (1837; new ed. with *Notice* by Prevost-Paradol, 4 vols. 1865), Louandre (4 vols. 1870), Dezeimeris and Barckhausen (2 vols. 1870-75), Motheau and Jouaust (2 vols. 1873-74), and Courbet and Roger, with Glossary (1 and 2 vols. 1874). See J. F. Payen, *Notice Bibliographique sur M. (1837)*;

Documents inédits ou peu connus sur M. (1847-56); Grün, *La Vie Publique de Michel M.* (1855); Malvesin, *Michel M., son Origine, sa Famille* (Bord. 1875).

Montalembert, Charles Forbes, Comte de, was born at London, 29th May 1810, began to study at the Scotch College, Paris, and finished at the Sainte-Barbe Institute. Along with Lamennais he took part in founding *L'Avenir* (1830), in which the principles of democracy and Catholicism were defended side by side, 'God and Liberty, the Pope and the People' being the motto under which the advocacy was maintained. He carried on with great earnestness and brilliancy a journalistic crusade in behalf of free Catholic education outside the influence of the university, and (May 1831) he opened a free school to embody his ideas. It was closed by order of the authorities, and M., who succeeded his father in the peerage that year, defended himself before the Chamber in an incisive and well-turned speech. But the increasing violence with which M. and his colleagues in *L'Avenir* were lashing the abuses of society, gave umbrage to the Church. The paper ceased to appear (1832), after an interview M. had with the Pope, the latter laying down the law that human guidance must be directed from the Church alone, and publishing an encyclical denouncing the alliance of democracy with Catholicism. M. retired to Germany for two years, where he wrote *L'Histoire de Sainte Elisabeth de Hongrie* (1836; 12th ed. 1868), and on his return took his place in the Chamber of Peers. In 1836 he married a daughter of the Belgian minister, in 1839 he visited London, and from Madeira in 1843 he launched a powerful *brochure*, calling Catholics to watch their interests upon the occasion of a new law being proposed in connection with secondary education. During the same period his speeches on points of policy which touched either the doctrines of political freedom or Catholic privilege, were much admired for their elegance, conscientiousness, and correctness. He accepted the revolution of 1848, and being returned to the Legislative Assembly, supported Louis Bonaparte until the *coup-d'état* drove him to resign. He was appointed a member of the French Academy in 1852. Five years later he retired altogether from political life, and devoted himself to literature. His familiarity with English institutions, for which he had a sincere admiration, often served in his political contributions to furnish contemporary contrasts with the state of matters in France. His greatest work, in spite of its inaccuracies, is *Les Moines d'Occident* (4 vols. 1861-67). It embraces the period between Benedict and Bernard, and is written with such lustrous beauty of language, such ardour of spiritual insight, that one thrills in responsive sympathy as he reads. Among M.'s other writings are *Du Devoir des Catholiques dans la Question de la Liberté d'Enseignement*; *L'Avenir politique de l'Angleterre*; *Pie IX. et Lord Palmerston*. *L'Espagne et la Liberté*, published in 1875, is, as its editor, Père Hyacinthe, remarks, 'in some sort his political, literary, and religious testament.' M. died 13th March 1871. See Mrs. Oliphant's *Memoir of the Comte de M.* (1872).

Montana, a western territory of the U.S., is bounded N. by the Dominion of Canada, S. by Wyoming and Idaho, E. by Dakota, and W. by Idaho. Area, 143,776 sq. miles; pop. (1870) 39,895, of whom 19,457 were Indians, 18,306 whites, 1949 Chinese, and 183 coloured. As its name indicates, M. is a country of mountains, traversed from N. to S. by the main range of the Rocky Mountains and by many lateral ranges, including the Bitter Root, Judith, and Belt Mountains. Its scenery is singularly grand and impressive, the physical features being on a scale of unsurpassed magnificence. The chief rivers are the Missouri (formed by the 'Three Forks'—the Galatin, Jefferson, and Madison), the Milk, and Yellowstone, and the Clark and other affluents of the Columbia, flowing W. to the Pacific. Among the mountains are many beautiful lakes, while the slopes and valleys are clad with forests of pine, spruce, cottonwood, cedar, aspen, &c. The S. boundary of M. encloses part of the remarkable Yellowstone National Park. The climate in the plains and valleys is very mild, the mean temperature ranging from 44° to 48°. In 1870, 139,537 acres had been taken up as farms, and the value of farm produce was \$1,676,660, and of animals slaughtered \$169,092. The chief crops are wheat, oats, barley, and potatoes. M., an excellent grazing country with abundance of 'bunch grass,' had 5289 horses, 12,432 milch cows, 24,306 other cattle, 2024 sheep, and 2599 swine. By far the principal industry is gold mining, and it is estimated

that since the discovery in 1861 the mines have yielded gold to the value of \$100,000,000. Placer, hydraulic, and quartz mining are carried on extensively. Of late years there has been some falling off in the enterprise, though many of the mines are as productive as ever. Other mineral products are silver, copper, lignite, and petroleum. Virginia City is the capital, and Helena the largest town, with a pop. of 3106. M. was organised as a separate territory in 1864.

Montanists were a heretical sect in the early Church, which was founded by Montanus, a Phrygian, who about 150 began to profess that he received revelations from the Holy Ghost amounting to a new dispensation superior to that of Christ and his apostles, and which was to supplement the latter, and bring the Church to perfection. Two fanatical women, Maximilla and Priscilla, attached themselves to him as prophetesses, with a number of other adherents, and a sect was formed. The prophesyings of Montanus, Maximilla, and Priscilla, which were received by the M. as revelations, related chiefly to the discipline of the Church. New fasts were prescribed: two Lents (q. v.) besides that observed by the Church, and two weeks of Xerophagy (Gr. *xēros*, 'dry, fasting,' and *phagein*, 'to eat'), that is, total abstinence from meat and drink and from ablutions. Second marriages were forbidden as no other than fornication. Unbounded value was attached to complete celibacy, and profound contempt expressed for everything earthly. Sins were divided into two classes, according to John v. 16, 17, for one of which the sacrament of penance was appointed, but the other—incontinence, murder, idolatry—excluded the sinner for ever from the Church, although not from the grace of God. Men were forbidden to flee from or buy off persecution, which is sent by God. Millenarianism, which was held by the Church generally during the first two centuries (See MILLENNIUM), seems to have been prominently held by the M. An after development of the doctrine of the M. was that Montanus himself was the Paraclete, so that they altered the baptismal formula to 'Father, Son, and Montanus.' The sect flourished chiefly in Asia, where it continued down to the 6th c. In the Western Church, chiefly owing to the advocacy of Tertullian, it gained a certain hold about the end of the 2d c., but became extinct, in name at least, after the 4th c.

Montargis, a town of France, department of Loiret, at the junction of the Canal d'Orleans, Canal de Briare, and Canal de Loing, 69 miles S.S.E. of Paris by rail. M. has considerable trade in cereals, wine, saffron, wool, and cattle, and manufactures serge, cutlery, hosiery, leather, and paper. Pop. (1872) 8104.

Montauban (*Mons Albanus*), a town in France, capital of the department of Tarn-et-Garonne, at the confluence of the Tarn and Tescou, and 31½ miles N.N.W. of Toulouse by rail. Most of the houses are built of brick. There are several fine public buildings, the most important being the cathedral (1739), which occupies the site of an ancient monastery called *Mons Aureolus*. There are considerable manufactures of woollens, cottons, silks, porcelain, flour, chemicals, and beet-sugar, and the town is a great entrepôt for the trade of Southern France. M. was founded in 1144, and was made a bishop's see in 1317. It was one of the chief Huguenot strongholds, and has the sole Protestant theological college in France. Pop. (1872) 16,635.

Montbéliard (*Mons Peliardis*; Ger. *Mömpelgard*), a town in the department of Doubs, France, at the confluence of the Alle and Luzine, 36 miles N.E. of Besançon by rail. It makes watches to the yearly value of a million francs, and has a large cotton industry. Pop. (1872) 6509.

Mont Blanc, the monarch of European mountains, and the central point of the Alpine system, belongs to the Graian Alps, forms (since 1860) part of the boundary between France and Italy, and towers to a height of 15,781 feet. It is a gigantic mass of granite and protogine, rising in steep rocky pyramids (*aiguilles*), and covers an area of 98 sq. miles. The waters of its fifty-six great glaciers (Mer de Glace, Glacier du Tour, d'Argentière, &c.) are carried off mainly to the W. by the Arve, through the beautiful Vale of Chamouny (q. v.), and E. by the Dora Baltea, an affluent of the Po, through the romantic valleys of Ferret and Allée Blanche. After M. B. itself, the chief heights are the Aiguille de Géant (13,156 feet), Les Jorasses (13,761), Aiguille Verte (11,218), Aiguille d'Argentière (12,569), and Aiguille du

Midi (12,608). The snow-line descends to 8000 feet. M. B. was first ascended by Balmat, a guide, in 1786, and again in 1787 by De Saussure, the naturalist. Since then the feat has been frequently performed. The ascent, which takes two or three days, and costs 250 francs a-head, is made now about forty times annually, and is attended by no serious danger, or even difficulty, unless in bad weather. A party of eleven persons perished in a storm during the ascent in 1870. See Eugène Viollet-le-Duc's *M. B., its Geological and Geological Constitution*, &c. (Eng. trans. 1877).

Montbrison, a town of France, in the department of Loire, on the Vizezy, 22 miles N.W. of St. Étienne by rail. Its chief buildings are the church of Notre-Dame-d'Espérance, the Mairie and Palais-de-Justice (both ancient convents), and a public library of 15,080 volumes. M. has tanneries, breweries, and a spinning-mill, and in the neighbourhood are three mineral springs. Pop. (1872) 5386.

Montcalm de Saint Véran, Louis Joseph, Marquis de, a celebrated French general, born at the Château de Candiac, near Nîmes, February 28, 1712, entered the army at the age of nine, obtained his captaincy (1729), and commanded the Auxerrois regiment in the battles of Plaisance and Exiles. Created a field-marshal (1756), he was immediately despatched to Canada, which was then threatened by an English invasion, and opened the campaign by the capture of Forts Oswego and Georges. Though to 60,000 English he could only oppose 3000 regulars, as many militiamen, and 1800 undisciplined Indians, M. inflicted a severe defeat on Lord Abercromby, under the wall of Ticonderoga (July 18, 1758). But in the following year three simultaneous attacks were made on Canada. Wolfe (q.v.), advancing on Quebec (June 27), was at first repulsed, but scaling the Heights of Abraham (September 13), he appeared in M.'s rear. In the great English victory that followed, both generals fell, M. surviving his rival only by a day. A monument raised in Quebec by Lord Dalhousie (1827) bears the following inscription: *Mortem virtus communem, famam historia, monumentum posteritas dedit.*

Mont-de-Marsan, a town of France, capital of the department of Landes, 61 miles N.W. of Tarbes by rail, on the Midouze, a navigable affluent of the Adour, formed by the confluence here of the Midou and Douze. The buildings, wholly modern, include a lyceum, theatre, and public library of 12,000 volumes. M. has ironworks, distilleries, and crushing-mills for linseed and colza oils, and carries on a busy transit trade with Bayonne in Armagnac wines and brandies. Pop. (1872) 6964.

Montebell'o, a village of N. Italy, province of Pavia, 23 miles E.N.E. of Alessandria, was the scene of a double defeat of the Austrians, first by the French under Lannes (q.v.), 9th June 1800, and again by the Franco-Sardinian forces, 20th May 1859.

Montecuculi, Raimondo, Count, was born at Modena in 1608, educated among the Jesuits, entered the Imperialist army, and in 1637 distinguished himself in Silesia by leading a charge of 2000 men against 10,000 Swedes. Taken prisoner in 1639 he was kept at Stettin for two years, where he devoted himself to science and a study of the art of war. He commanded the army which in 1657 assisted the king of Poland against the princes of Sweden and Transylvania, and in 1658 he, as Field-Marshal, helped the king of Denmark to drive the Swedes from Jutland. For some years he operated against the Turks, and at last, from a strong position on the banks of the Raab, he was able to rout them in their attempted passage across the river (August 1664). When war broke out between France and Holland, the Emperor took part with the latter, and in the autumn of 1673 M. led an army from Bohemia to the assistance of William of Orange, and, though watched by Turenne, outmanœuvred him, joined the Stadtholder, and captured Bonn. He was killed by accident at Linz, 16th October 1681. His writings were published by Ugo Foscolo (2 vols. Mil. 1807), and again by Grassi (2 vols. Tur. 1821). His Memoirs were published at Vienna in Latin in 1718.

Montefiore, Sir Moses, a Jewish philanthropist, the descendant of a wealthy family of bankers, was born in London, October 24, 1784. He was knighted in 1837, when he held the office of Sheriff of London, and was created a baronet in 1846. Since 1840 he has undertaken various missions to the

East on behalf of his co-religionists, and his earnest, unwearied, and successful services in procuring kindlier laws and greater freedom for them in many states, notably in Poland, Morocco, and Turkey, has made his name revered throughout the world-wide Hebrew community. His philanthropy has also been exerted in favour of oppressed Christian subjects in Mohammedan countries. He endowed a Jewish college at Ramsgate in 1867 in memory of his wife Judith (author of *Notes of a Visit to Egypt and Palestine*, 1844). On more than one occasion he has received the thanks of the Corporation of London for his humane efforts, and in 1873 he was presented with the freedom of the City. In June 1875, when over 90 years of age, he undertook a mission of investigation into the condition of the Jews at Jerusalem, and a special thanksgiving service for his safe return was held in the following September at the Great Synagogue, London. See Picciotto's *Anglo-Jewish History* (London, 1876).

Monte'go Bay, a seaport of Jamaica, in the N.W. of the island, 100 miles W.N.W. of Kingston. It has a good harbour, and a declining trade in sugar, rum, molasses, &c. M. has long been the seat of a U.P. mission. Pop. about 5000.

Monteleone (the *Hippionum* of the Greeks, and *Vibo Valentia* of the Romans), a town of Southern Italy, in the province of Catanzaro, 48½ miles S.S.W. of Cosenza, and 3 miles distant from the Gulf of St. Eufemia. It has manufactures of silk, and a trade in fruits and wine; played an important part in the Neapolitan wars of the Middle Ages; and suffered greatly from the earthquake of 1783, in which its castle, erected by Friedrich II., was almost totally destroyed. Pop. (1874) 11,840.

Montélimar, a town in S. France, department of Drôme, at the junction of the Rubion and Jabron, near the left bank of the Rhone, 213 feet above the sea, and 49½ miles N. of Avignon by rail. M. has considerable trade in wine, truffles, and raw silk, and manufactures leather, bricks, and confectionery. M. dates from the Roman period, and in the middle ages was called *Montilium Leopardi*. Pop. (1872) 7737.

Montem, the triennial Whit-Tuesday festival of the Eton scholars, who, dressed in rich, fanciful habits, marched to 'Salt Hill,' a tumulus near the Bath Road, where 'salt'—money for the support of the captain of the school at King's College, Cambridge—having been collected among the spectators, they were sumptuously entertained at the Windmill Inn. According to an account in the *Courier* of 1799, the King and Royal Family graced the proceedings, the members of the procession numbered twenty-seven, and the 'salt' collected amounted to £800. Prior to 1759 the E. M. fell on December 6, the feast of St. Nicholas, whence it would seem to have been a relic of the installation of the Boy-Bishop (q.v.). Since 1847 a regatta has taken its place.

Montemayor, Jorge de, a famous Spanish poet, born about 1515 at Montemayor, near Coimbra in Portugal, served for some time in the army, but afterwards went to Castile, and became a singer in the royal chapel. He accompanied Philip II. on his visit to Germany, Italy, and the Low Countries. Later, the Queen of Portugal, Philip's aunt, invited him to her court. M. fell, it is supposed, in a duel in Italy about 1562. By his brilliant though unfinished *Diana Enamorada* (1st ed. 1545; mod. ed., Madrid, 1802), he became the founder of the Spanish pastoral romance, which exercised a wide influence in Western Europe. The *Diana* comprises seven books, partly in prose and partly in verse, and is distinguished by its inexhaustible fund of tender sentiments, and by the dignity and harmony of its versification. He also wrote a number of poems, first published at Antwerp in 1554, under the title of *Obras*, but in subsequent editions the collection was termed *Cancionero*. See Ticknor's *History of Spanish Literature*.

Montenegro (the 'Black Mountain,' so called from the dark forests with which it is covered; the Turkish name is *Kara-Dagh*, and the Montenegrin *Tiernagora* have the same meaning), a principality over which Turkey claimed, though it never exercised, suzerainty, lies near the Adriatic, and is bounded W. by Dalmatia, N. by Herzegovina, E. by Bosnia, and S. by Albania. It has an area of 1770 English sq. miles. The country is mountainous in the extreme (Kutch Kom, the highest peak, is 9300 feet above the sea-level), and is well watered,

the chief stream, the Moratsha, falling into Lake Scutari. The ground is rocky and sterile, and the climate is cold but healthy. The products are chiefly maize, potatoes, tobacco, fish, honey, and smoked mutton, and there is an abundance of cattle, sheep, and pigs. Wine, brandy, sugar, arms, sandals, &c., are imported. Fear of invasion has prevented the formation of any roads, and all goods are carried along the narrow footpaths by women on horses. The chief markets for the principality are Cattaro and Kassinio. The country is divided into 8 districts or nahijas. The villages (310 in number) are mere collections of hovels, and the capital, Cetinje, consists of a single street, with about 40 respectably-sized houses. The pop. was estimated in 1871 to be 195,585, and the number of men capable of bearing arms (ages 20 to 50), 21,850. The people as a rule are a tall, powerful, high-spirited race; but they are quite illiterate, and have necessarily the savage qualities engendered by four centuries of desperate fighting for independence. Their government is patriarchal. They are divided into 40 tribes, each ruled by elders and a chief called Knja, who acts as magistrate during peace, and commander in war. The assembled Knjas form the *Skupstchina*, or Montenegrin Parliament. A Prince-Bishop or Vladika of the House of Petrovitch, was both temporal and spiritual ruler from 1697 till 1852, when Danilo I. (who introduced important internal reforms) proclaimed himself Hospodar or secular prince. The Hospodar possessed the entire revenues of the country till 1868, when instead thereof a civil list was given him of 2000 ducats (£350), augmented by a grant from Russia of 8000 ducats (£1400), and from France of 50,000 francs (£2000). The religion is that of the Greek Church (incorporated with the Holy Synod of Russia since 1852), and there are some 200 priests, many of whom are unable to read, who follow ordinary secular occupations, and are liable for military service. The convents are those of Cetinje, Ostrog, and St. Stefano. The language is a pure dialect of the Illyrico-Servian branch of the Slavic.

History.—On the conquest of the ancient kingdom of Servia by Turkey (1389), M., then known as Zeta, continued to assert its independence, and maintained a chronic warfare with the Porte down to the close of the Russo-Turkish war of 1877–78. Among the most notable campaigns are those of 1623, 1712, and 1768, in which latter year 20,000 Turks were slain. In 1820, and again in 1830, Turkish invasions were successfully repelled. Omar Pasha entered the principality in 1852, but withdrew on intervention by the great powers. Fresh collisions took place in 1858. The Montenegrins favoured the Herzegovinian insurrection of 1861, but on Omar Pasha's appearance before the capital concluded peace, and for the first time acknowledged the suzerainty of Turkey. Complications arose in 1874 and 1875. On July 2, 1876, war was once more declared, and in the campaign of that year Prince Nikita defeated Mukhtar and Dervish Pashas, who suffered severe losses. After the armistice, October 1876–March 1877, Suleiman Pasha marched his army through the Duga Pass from Nicksics to Podgoritz at a fearful sacrifice of life, and would probably have crushed the principality, had not the appearance of the Russians in Bulgaria called his forces to the Balkans. Nicksics, the Turkish stronghold to the N. of the principality, left to itself, capitulated September 8, 1877, to the Montenegrins, whose independence, won by their own indomitable valour, and secured by the triumph of the Russian arms, was formally affirmed by the Treaty of Berlin, July 1878. See Lady Strangford's *Eastern Shores of the Adriatic* (Lond. 1864); J. G. Williamson's *Dalmatia and M.* (1848); *Le Servie et le M.*, by Reinach (Par. 1876); *Le M. Contemporain*, by Foilleay and Wlahovitch (Par. 1876); *Der Krieg: M.'s im Jahre 1876*, by Gopcevic (Vien. 1877); *M.*, by the Right Honourable W. E. Gladstone, in the *Nineteenth Century*, May 1877; *M., its People and their History*, by the Rev. W. Denton (1877); and Gossip, *Turkey and Russia, their Races, Histories, and Wars* (T. C. Jack, Edinb. 1878).

Montepulcia'no, a town of Italy, province of Siena, 29 miles S.E. of the city of Siena, and about twice as far S.S.E. of Florence. It is built on a spur of the extinct volcano Monte Amiata (5644 ft.), has an old castle, a fine cathedral, and several well-built churches. The whole hill is covered with beautiful vineyards, which yield a wine that ranks among the finest in Italy. Pop. of town (1874), 2813; but with the suburbs, 13,160.

Montereau-Faut-Yonne, a town of France, department Seine-et-Marne, at the confluence of the Yonne and Seine, 17 miles S.E. of Melun, and connected with Paris by a railway. Pop. (1872) 6714. It has manufactures of earthenware and leather, and has considerable commerce in cereals, wines, and cattle. The 'Bridge' of M. is historically memorable as the scene of the assassination (1419) of John 'the Fearless,' Duke of Burgundy, by Tanneguy Duchâtel, one of the chiefs of the Orleanist party.

Monterey, a town of Mexico, capital of the province Nuevo Leon, on a small tributary of the San Juan, which joins the Rio Grande 110 miles E.N.E. of the town, and the same distance W.N.W. of the Gulf of Mexico. It has considerable manufacturing industry, and has a flourishing trade with the United States. Pop. (1869) 13,500. In the war of 1846, it capitulated after four days' siege to the American forces under General Taylor.

Mon'te Ro'sa, an Alpine group of nine lofty peaks, on the boundary between Piedmont and the Swiss Canton Valais. They are situated between the Pennine and Lepontine Alps, and are chiefly composed of felsite. The highest peak, Dufourspitze, is 15,217 feet high; the others are Nordende (15,132), Zumsteinspitze (15,004), Signalkuppe (14,964), Parrotspitze (14,577), Ludwigshöhe (14,219), Schwarzhorn (14,098), Balmenhorn (14,187), Vincent-pyramide (13,816), and Jagerhorn (13,042). The system is very rich in glaciers, the Lys-glacier and Cornet-glacier being the finest. Minerals are very abundant, but have not yet been worked to advantage.

Mon'te San Giulia'no, a town of Sicily, province of Trapani, 6 miles E.N.E. of the town of Trapani, stands on an isolated mountain (anc. *Eryx*) 2464 feet high. It has an ivy-clad castle of Saracen origin, and a cathedral somewhat 'restored' in 1865. Pop. (1874) 3056, rapidly falling off on account of migrations to the plain. On the mountain are the remains of a temple of Venus.

Mon'te Sant' An'gelo, a town of Southern Italy, province of Foggia, a few miles from the N. shore of the Gulf of Manfredonia, and 28 miles N.E. of the city of Foggia. Pop. (1874) 13,948. It has a picturesque castle and a famous old sanctuary of St. Michele. The vegetation in the vicinity is very luxuriant.

Mon'te Sar'chio, a town of Southern Italy, province of Benevento, 7 miles S.W. of the town of Benevento. Pop. (1874) 4880. Its castle, once the residence of the D'Avalos family, has been recently used as a state prison.

Montespan, Françoise, Athenais, Marquise de, daughter of Rochecouart Duc de Mortmart, was born in 1641, and in her youth bore the name of Mlle. de Tounay-Charente. In 1661 she was married to the Marquis de M., who brought her to the Court of Louis XIV., where her beauty and vivacity soon attracted the notice of the monarch. She superseded the soft La Vallière in the royal regards, and after 1667 received his exclusive devotion. The Marquis de M. did not accept the situation with the grace of a courtier, and was, in consequence, successively imprisoned in the Bastille, banished to Cayenne, and finally divorced. But M. was doomed to be superseded in turn. She required a governess for the children whom she had borne to the king, and the lady whose services she obtained (Madame Maintenon), robbed her of his affections. In 1686 Louis finally broke off his relations with M., who in 1691 was ordered to leave Paris. She entered the order of the Daughters of St. James, and died 27th May 1707. By her intercourse with Louis she had three sons, the Duc de Maine, the Comte de Vexin, and the Comte de Toulouse, and three daughters, Mlle. de Nantes, married to the Duc de Bourbon; Mlle. de Tours (died 1681), and Mlle. de Blois, married to the Duc d'Orleans; besides other children who died young. M. was ambitious and haughty, and enjoyed the splendour of her shame. See *Mémoires de Madame la Marquise de M.* (2 vols. Par. 1829).

Montesquieu, Charles de Secondat, Baron de la Brède et de, a famous political philosopher, belonged to one of the best families of Guyenne, and was born 18th January 1689, at the Château de la Brède, near Bordeaux. From his

youth he was devoted to classical study, and in his twentieth year composed a treatise, never published, arguing in behalf of the salvation of pagans. On the 24th February 1714 he was appointed Councillor to the Parliament of Bordeaux, but his tastes lay more in the direction of the philosophy than in the details of jurisprudence. In 1721 he published the *Lettres Persanes*, a work in which he subjects to criticism, from the point of view of a foreigner, the complete circle of the national life. Its lively colouring and incisive observation gained him admission to the French Academy (1728), though there is a story current that, to turn aside the opposition of Cardinal Fleury, he published an edition with the objectionable passages cut out. M. resigned his post at Bordeaux in 1726, travelled in Austria, Hungary, Italy, Switzerland, and England, where he made the friendship of Lord Chesterfield and was elected a member of the Royal Society. On his return to France, he devoted himself for some years to the study of Roman history, and published in 1734 *Considérations sur les Causes de la Grandeur et de la Décadence des Romains*. In 1748 appeared his masterpiece, *L'Esprit des Loix*, in which politics were approached from a scientific aspect, and the character of the various forms of government analysed with precision and without partiality. The book was one of the forces which distinctly helped to produce the French Revolution. M. Demogot says: 'M. is in turn the Voltaire and the Rousseau of the Revolution, but a Voltaire timid, circumspect, veiling his opinions in allusions and subtle censures that could not be impugned; . . . a Rousseau turned jurisconsult and historian, without passion, without a dream of the ideal, noting the facts and realities of the Past, satisfied with finding the "reason" of everything, and preferring to "explain" existing institutions rather than to change them.' M. died at Paris, February 10, 1755. Innumerable editions of his principal works have appeared, and his *Œuvres Complètes* have been very frequently published with the notes and comments of Helvetius, Voltaire, Mably, Cravier, La Harpe, &c. We may cite in particular the editions of 1799 (8 vols.), of 1816 (6 vols.), of 1819 (8 vols.), of 1826 (8 vols.), and of 1862 (2 vols.). See Louis Vian's *Histoire de M., sa Vie et ses Œuvres* (Par. 1878), which is full of fresh and valuable matter, and must supersede all previous biographies.

Monteverde, Claudio, an Italian composer, born at Cremona in 1568, and died at Venice in 1649. He produced many pieces of sacred music, several operas, including *Orfeo* and *Ariana*, and five books of motets and madrigals.

Monte Vidéo, San Felipe de, the capital of the S. American Republic of Uruguay, lies on the N. shore of the mouth of the Rio de la Plata (here 65 miles wide), 132 miles E. by S. of Buenos Ayres. It is regularly built, the streets running down from a steep hill to the sea, which surrounds M. V. on three sides. The finest building is the cathedral, in the Italian style, in front of which is the Plaza de la Constitución. There are three other Catholic churches, San Francisco, La Caridad, and Los Ejercicios, a Protestant church (built 1846), and a Methodist chapel, an opera-house, several theatres, and a large hospital, the best in S. America. The harbour is fortified, and is commodious, but is neither deep nor well-protected from the W. and S.W. winds. There is a dry dock admitting vessels 275 feet long, and two others are in progress, one of which will take in ships of 420 feet. In 1875 there entered the port of M. V. 1658 vessels, of 953,605 tons (British 330, of 419,435 tons); cleared 1720, of 987,935 tons (British 346, of 430,474 tons). The chief exports are skins, wool, tallow, dried fish, oil, and extract of meat (36,000 cases in 1875); and imports wine, spirits, flour, cottons, woollens, and hardware. In 1875 the custom-house receipts amounted to \$4,359,398. M. V. is connected by railway with San José, Florida, and Duragno, and a line to the Brazilian frontier was begun in 1874. Pop. (1872) 105,295.

Montez, Lola, was born about 1820. Her birthplace is variously given as Seville, Limerick, and Montrose in Scotland. After an adventurous life in London, Paris, and Brussels, she came to Munich in 1846, won the favour of King Ludwig I. of Bavaria, who made her Countess of Landsfeld. She moulded in some degree the policy of the Bavarian Court, and was opposed to the Ultramontanes. In consequence of public dis-

turbances caused by her own rashness and pride, she was expelled from the country in February 1848, returned to England, thence went to North America in 1852, where she excited a great furor as an actress, and latterly became a lecturer on social and moral questions. She published an *Autobiography*, and died at New York, 30th June 1861.

Montezuma I., the greatest of Mexican monarchs, succeeded Itzcoatl in 1436, and immediately began the subjugation of hostile neighbours, annihilating the Chalchese, defeating and killing the King of Tlatelolco, adding to his dominions the province of Cuixicas—a tract of country 150 miles broad—next conquering another province called Tzompahuacan, subduing the powerful Mixtacas, and finally annexing the province of Cotasta in 1457. He died during a most disastrous famine.—**M. II.**, grandson of the preceding, reigned when Mexico was invaded by the Spaniards in 1519. At first, forbidding Cortes to move inland, he only excited the cupidity of his foes by the rich presents he sent them; and Cortes, making friends of several disaffected tribes, proceeded with their assistance to the capital. A plot formed by M. for their destruction at Cholula was discovered by the invaders, who, marching on the city, slew 6000 Cholulans, without the loss of a single Spaniard. Cortes on capturing Mexico kept M. a hostage, but released him on his acknowledging himself a vassal of Spain. He would never embrace the Christian religion however. Attempting afterwards to pacify some native insurgents, he was attacked by the infuriated mob as a traitor, and died from wounds caused by stones thrown at him, June 30th, 1520. See Robertson's *History of America*, and W. A. Prescott's *History of the Conquest of Mexico*.

Montfaucon, Bernard de, a French antiquary, born January 13, 1655, at the château of Soulague in Languedoc, served under Turenne, but in 1676 entered the Benedictine monastery of St. Maur, where he applied himself to the study of philosophy, theology, history, literature, and the dead and living languages. He received the post of keeper of the collection of medals at St. Germain des Prés (1694), made an antiquarian tour in Italy (1698-1701), was admitted member of the Academy of Inscriptions (1719), and died at Paris, in the abbey of St. Germain des Prés, December 21, 1741. In folio alone, M. published forty-four different works, among them *Diarium Italicum* (Par. 1702; Eng. trans. 1725), *L'Antiquité appliquée et représentée en Figures* (15 vols. Par. 1719-24), and editions of Athanasius (1693), the Greek Fathers (1706), Chrysostom (1718), *Bibliotheca Bibliothecarum Manuscriptorum Nova* (2 vols. 1739), &c.

Montferrat. See MONFERRATO.

Montfort, a French family who derived their origin from Baldwin, Comte de Flanders, and Judith, daughter of Karl the Bald. M. was a small town between Paris and Chartres, and **Amalric II.**, its seigneur, is the first name which emerges in the chronicles (11th c.). **Simon I.**, his son, was thrice married, had four sons, each of whom succeeded him in turn—**Amalric IV.**, the last of these, being long engaged with Henry I. of England in a quarrel concerning his heritage d'Evreux. **Simon III.**, his grandson, married Amicie, daughter of Robert de Beaumont, Earl of Leicester; and his second son, **Simon IV.**, distinguished himself as a persecutor of the Albigensian heretics, went on the 5th crusade (1202), held the titles Comte de M., Earl of Leicester, and Comte de Toulouse, in making good his claims to which he perished. His fourth son, **Simon de M.** was born in France about 1206; in 1226, two intermediate brothers being dead, he appeared at the Council of Bourges to claim the countship of Toulouse. Failing in that, M. crossed to England, where, after a few years, he got the consent of his brothers and Henry III. to enter upon the earldom of Leicester (1239). He had previously made a clandestine marriage with Eleanor, sister of the king. This marriage so irritated the nobles and Henry that M. had to leave England in order to get it legally recognised. In 1244 his name appears as one of a committee of barons appointed to treat with the king in respect of his exactions, and in 1249 he was sent to Gascony with the title of Seneschal, where he ruled with an iron hand. On his return, he became the leader of the English baronage in resisting royal encroachments, and in 1258 was one of the twelve chosen to put the Provisions of Oxford into execution; and to him were more especially due

the ordinances known as the Provisions of Westminster, by which the grievances of the barons were overtaken. For a year the provisional government thus established worked well enough, but in 1261 Henry repudiated the oaths he had taken, and, under M.'s supervision, preparations were made for war. In 1263, M. compelled him thrice to confirm the Provisions, and in the same year, when the whole question of dispute was referred to the arbitration of Louis IX. of France, M. was the only Earl who appeared against the King. Next year, the award being in favour of the Crown, M. took up arms, and though success was at first on the side of the King, he captured Warwick, besieged Rochester, and collected his forces at Lewes, where he offered to buy off the King if he would confirm the Provisions. A battle was fought, Henry and his son fell into Simon's hands, and he ruled the country for a year in their name. A new constitution was devised, under which the King was compelled to act under the advice of nine counsellors, three of whom were to be in constant attendance upon him. Of these, M. was one, and (December 1264) he called the Parliament known by his name, to which, for the first time, borough representatives were invited. But a feud arose between the family of M. and Gloucester, which developed into a war and culminated at Evesham, where he fell, August 4th, 1265. 'He stands out,' writes Professor Stubbs, 'best and most grandly in comparison with the meanness with which he was surrounded—the paltry faithless King, the selfish and unscrupulous baronage. He is relatively great; but he is not perfect. He is scarcely a patriot—a foreigner could hardly be expected to be so. He is somewhat more distinctly a hero, but he never quite rids himself of the character of the adventurer.' (See Stubbs' *Constitutional History of England* and *The Early Plantagenets* (Lond. 1873); Freeman's *History of the Norman Conquest* (1867-76); Crichton's *Life of Simon de M., Earl of Leicester* (Lond. 1876); Prothero's *Life of Simon de M., Earl of Leicester, with special Reference to the Parliamentary History of his Time* (Lond. 1877).

Montgolfier, Jacques Etienne, was born (7th January 1745) at Vidalon-lès-Annonais, near Lyon in France, where, with his brother, **Joseph Michel M.** (born 1740), he carried on a paper manufactory. They devoted much attention to physical science, and invented (1783) the air-balloon, called after them 'Mongolière,' for which they were both admitted to the Academy. Etienne died at Servières, 2d August 1799. His brother invented the *bélier hydraulique* and the calorimeter, was made a member of the Institute in 1807, and died 26th June 1810.

Montgom'erie, the name of the Eglinton family, is derived from Roger de M., kinsman of William of Normandy, the first body of whose army he commanded at Hastings. Roger obtained the earldom of Shrewsbury. His grandson Robert came to Scotland in the reign of David I., and obtained the manor of Eaglesham (Eglesham) in Renfrew, which was for two centuries the chief seat of the Scottish Montgomeries, and still remains in the possession of the family. He is a witness to the foundation-charter of the monastery of Paisley in 1160, and died about 1175. A lineal descendant of his, Sir John M., seventh Baron of Eaglesham, married Elizabeth, daughter of Sir Hugh Eglintoun of Eglintoun, daughter and heiress of the Justiciar of Lothians, and niece of Robert II., and obtained with her the baronies of Eglinton and Ardrossan. The ballad of *Chevy Chase* records the death of one of Sir John's sons, Sir Hugh; and his brother, Sir John, who succeeded to the estates, was one of the hostages sent to England to ransom James I.—**Alexander**, his son, became Lord M. in 1449; and his great-grandson Hugh was created Earl of Eglinton in 1508. The title passed to another branch of the family in Alexander Seton, sixth Earl (1612), surnamed Greysteel, who fought against his own son and heir in the Parliament army at Marston Moor. He subsequently espoused the cause of Charles II.—**Archibald**, eleventh Earl, having no male issue, the title passed to Hugh M., who became a peer as Baron Ardrossan in 1806.—His son, **Archibald William**, K.T., D.C.L., LL.D., born in 1812, succeeded to the title of Earl of Winton in Scotland, 1840, and was granted the same title in the United Kingdom, 1859. It was he who held the celebrated tournament at Eglinton Castle in 1839. He was Lord-Lieutenant of Ireland during the Derby Ministries of 1852 and 1853, and was personally the most popular representative the British Crown ever had in that troubled land. In his own land of Ayrshire his dignified yet winning and benignant manners secured him

an unbounded popularity. He greatly loved Burns, and learned from his verse the way to reach the hearts of his fellow-men. When the foundation-stone of the Burns Monument at Ayr was laid in 1844 with something like national honours, his was the noblest tribute of eloquence paid to the memory of the 'Ayrshire Bard.' He died 4th October 1861.—His son, **Archibald William**, fourteenth Earl of Eglinton, Lord M., Lord Seton and Tranent in the Scotch peerage, Earl of Winton and Baron Ardrossan in that of the United Kingdom, was born 3d December 1841, and married a daughter of the Earl of Yarborough, 6th December 1862, by whom he has several daughters. He has not yet taken any part in public affairs, but in 1876 he somewhat startled his countrymen by expressing his inability to admire the poet whom his father loved and honoured. See *Fraser's Memorials of the Montgomeries* (2 vols. 1859).

Montgomery, the capital of Montgomeryshire, in North Wales, on the Severn, 26 miles S.W. of Shrewsbury by rail. Its castle, of which the tower and parts of the wall still remain, was built in 1093 by Roger de M., whose name the town still preserves. M. has a trade in country produce, and is one of the M. district of boroughs, which returns one member to Parliament. Pop. (1870) 1285.

Montgomery, capital of Alabama, U.S., on the left bank of the Alabama River, 150 miles N.N.W. of Pensacola by rail. A great cotton-mart, and capital of the Confederate States till 1860, it has a fine State-house, standing on high ground overlooking M. city, also 12 churches, 4 daily newspapers, a large flour-mill, several machine-shops and foundries, &c. Within 60 miles of M. are extensive coal and iron deposits. Pop. (1870) 10,588.

Montgomery, a district in the Punjab, British India, lying between Lahore and Mooltan, in the *doab* of the Sutlej and the Creanaub. Area, 5573 sq. miles; pop. (1868) 359,437. No rain falls, but the country is irrigated by an indigenous system of canals and Persian wheels. The staple crop is wheat, and dates, oranges, and pomegranates abound. The towns are Kamaliah and Pakpattan. The name is derived from *Sir Henry M.*, a distinguished administrator of the Punjab under the Lawrences, and like them of Irish origin.

Montgomery, Alexander, a Scottish poet of James VI.'s time, born at Hazelhead Castle, Ayrshire, seems to have been an officer in the guard of the Regent Morton. What services he rendered the king cannot be ascertained; but from 1582 he enjoyed a pension of five hundred marks per annum. In 1586 he got royal licence to travel for five years on the Continent; and it is certain he was confined for a time in some foreign prison. The dates of his compositions are unknown. Three short poems are quoted in Bannatyne's MS. (1568). His most famous poem, *The Cherry and the Slae*, a long love allegory—virtue represented by the cherry, vice by the sloe—was first printed by Waldegrave in 1597. For the whole of his compositions see the edition prepared by Laing, with memoirs by Irving (ed. 1821). It is probable that M. survived at least till 1605, when his *Mindes Melodie* was printed by Charteris.

Montgomery, James, an English poet of Scottish origin, was born at Irvine, Ayrshire, November 4, 1771. His father, the Rev. John M., a Moravian missionary, went in 1783 to preach the gospel to the slaves in the W. Indies, and died at Barbadoes in 1791. Young M. was meanwhile being educated at the Moravian Seminary of Fulneck, near Leeds. He began the world as a grocer's shop-boy. After much wandering, he started a newspaper in Sheffield (1794), but as editor of the *Irish* was twice fined and imprisoned for what were regarded as offences against Government. Those were the dark days of a triumphant and cruel Toryism. While incarcerated in York Castle he wrote *Prison Amusements*, by *Paul Positive* (1797). It may be noticed that the persecution which encircled him with a gentle halo of martyrdom contributed to the popularity of his subsequent writings. They were received with a cordiality to which their intrinsic merits did not entitle them. Some of his hymns and shorter pieces, however, exhibit the qualities of true poetry, and are embued with a purity of Christian sentiment that has never been surpassed. M. died at Sheffield, 30th April 1854. His chief works are *The Wanderer of Switzerland* (1806; 9th ed. 1822), *The West Indies* (1809), *The World before the Flood* (1813), *Greenland* (1819),

The Christian Psalmist, or Hymns Selected and Original (1825), *Prose by a Poet* (1824), *The Pelican Island* (1827). His complete works appeared in 1855. See his *Memoirs* by Holland and Everett (6 vols. 1854-56), and *Life and Times*, by Ellis (1864).

Montgomeryshire, a county of Wales, England, is bounded N. by Denbigh, S. by Radnor, W. by Merioneth and Cardigan, and E. by Shropshire. Area, 485,351 acres; pop. (1870) 67,633. It is almost entirely mountainous, of Silurian formation, and belongs to the basin of the Severn, except a small part in the extreme W., which is drained by the Dovey. The chief heights are Cader Berwyn, on the N. boundary, 2563 feet high, and Rhydo Hywell, in the Kerry Hills in the S., 1895 feet. Plinlimmon is partly in M., but its summit, 2463 feet, is just within Cardiganshire. Affluents of the Severn that water M. are Vyrnwy, Tanat, and Rhin; the Wye rises in the S. of the county. The valleys are fertile and woody, but a great part of the surface consists of moorland sheepwalks. The sheep are celebrated, as are also the 'Merlins,' a pure breed of Welsh ponies. In 1876 there were 53,268 acres under corn crops, 12,314 under green crops, 30,456 in clover, sanfoin, and grasses in rotation, and 148,890 in permanent pasture, exclusive of mountains and heath. M. had (1876) 13,885 horses, 64,474 cattle, 353,604 sheep, and 22,164 pigs. The chief crops are wheat, oats, barley, potatoes, and turnips. Slate is the principal mineral product, but lead and silver are also mined. In 1873 the yield of lead ore was 7977 tons, and of silver 54,957 oz. Flannel is the staple manufacture. M. is the capital, and other towns are Welshpool, Newtown, and Llanidloes. The county sends one member to Parliament.

Month (from a Sansk. root, *ma*, 'to measure') is strictly the period of the moon's revolution round the earth. The ordinary lunar M., or lunation, or synodical M., is the time in which the moon goes through all her phases, as from new moon to new moon. Its mean value is 29.530589 days. It is longer than the sidereal M., or time the moon takes to pass through the twelve signs of the zodiac, since in virtue of the earth's circumsolar motion the moon has always to advance through several degrees before coming to its former position relatively to the earth and sun. The mean value of the sidereal M. is 27.321661 days, and is the true period of revolution. For *Calendar M.*, see CALENDAR.

Montholon, Charles Tristran, Marquis de, born at Paris in 1782, became a midshipman when ten, at eighteen entered the army, and, rising rapidly, played a distinguished part in the campaigns of Italy, Austria, Prussia, and Poland. After Wagram Napoleon made him Comte, and attached him to his person. During the first restoration M., when all his relatives and friends paid court to the Bourbons, remained faithful to his master, whom he again joined as aide-de-camp, acting in that capacity at Waterloo. He attended Napoleon to the end at St. Helena, performing the duties of private secretary, and preparing, along with General Gourgaud, *Mémoires pour servir à l'Histoire de France sous Napoléon, écrits à Sainte Hélène sous sa Dictée* (1823). Lending countenance to the schemes of Louis Napoleon in 1840, he was condemned to twenty years' imprisonment, but afterwards pardoned. In England he published *Récits de la Captivité de Napoléon à Sainte Hélène* (1847). He also wrote *De l'Armée Française* (1834), and *Fragments Religieux inédits de Napoléon, recueillis à Sainte Hélène* (1841). He died on 21st August 1853.

Monti, Vincen'zo, an Italian poet of the Classicist school, was born at Fusignano, near Ravenna, February 19, 1754, and studied at Faenza and Ferrara. Coming to Rome in 1778, he became secretary to Luigi Braschi, nephew of Pio VI., and in rivalry with Alfieri produced the tragedies of *Aristodemo* (1787) and *Manfredi* (1788). His next and greatest work, *Basvilliana* (1793), applauds the murder of Hugo de Basville, the agent of the French Republic, and denounces in Dantesque language the Reign of Terror. Yet on the French occupation of Italy M. became secretary of the Cisalpine Republic, and taking refuge in Paris from the invasion of Suwarrow, there composed his *Cantica* on the death of Mascheroni (1800), in which Louis XVI., the 'innocent lamb' of the preceding epic, figures as 'a pitiless tyrant.' He returned to Italy shortly after Marengo, and became Professor of Eloquence at Pavia, and in 1805 historiographer to the newly-founded kingdom of Italy. Napoleon's fall M. signalled by an ode in honour of the return of Astræa, of Justice, that is, in the person of Franz I. He died at Milan,

October 13, 1827. A complete edition of his works appeared under the title *Prosa e Poesie* (5 vols. Flor. 1847). See Bozzoli, *Ragionamento della Vita e delle Opere di M.* (Fer. 1837).

Montilla, a town of Spain, province of Cordova, 23 miles S.E. of the city of Cordova, on the line of railway connecting that city with Malaga. It has linen and earthenware manufactures, and the neighbouring country known as Campina yields grain, oil, and superior wine. Pop. 12,100.

Montjoie St. Denis (from La Montjoie de St. Denis, an eminence near Paris, where St. Denis suffered martyrdom), the war-cry of the French during the middle ages. Montjoie thence became the title of the King-of-arms in France, and was also the name of an order of chivalry instituted in the 12th c. by Pope Alexander III. to combat the Saracens.

Montluçon, a town of France, department of Allier, on the right bank of the Cher, 45 miles S.W. of Moulins by rail. It has a Romano-Byzantine church (St. Pierre), another (Notre Dame) dating from the 14th c., manufactures of iron-ware, fine mirrors, leather, chemicals, &c. The famous mineral baths of Nérès are 10 miles S.E. of M. Pop. (1872) 21,247.

Montmorency first appears in French history in 958 as the name of a château, whose proprietor, Burchard, founded the family. In 1100 we find the lord of M. disputing with Louis VI. for the plains of St. Denis, and afterwards taken prisoner at the battle of Brenneville. **Matthieu de M.** accompanied Philippe-Auguste on his crusade of 1190. In 1492 was born **Anne**, who became the first Duc de M., a marshal and a constable of France. He was the centre of the 'high Catholic party,' and acted as their 'secular arm.' Over François I. he had for a time great influence, and was taken prisoner with him at the battle of Pavia. He formed one of the 'black court' of Henri II., and during the Italian war took Metz by guile. Though he led an army against Karl V., the sluggishness with which he carried on war in Picardy, and his skillless conduct at the battle of St. Quentin, lost him his influence, which declined still more on the death of the king and the consequent rise of the Guises. His detestation of the Huguenots, and his financial interests drew him to the side of that family, and in 1561 he became a member of the Triumvirate. Against the Huguenots he operated with success in the wars of 1562-67, but died of a wound received at the battle of St. Denis, November 12, 1567. He has been described as 'a brutal devotee, the typical fanatic of ignorance and reaction.'—The traditions of the house were maintained by his sons **François** (born 1530, died 1579) and **Henri** (born 1534, died 1614), each of whom was in turn Duc de M.—**Henry II.**, son of the latter, and fourth Duc de M., born at Chantilly, 31st April 1575, became an admiral in his seventeenth year, routed the Huguenots in Languedoc, was appointed commander-in-chief of the French army in Piedmont, 1630, and rose to be a maréchal. His brilliant career was brought to a close at the block, 30th October 1632, on account of his treasonable alliance with Gaston, Duc d'Orléans. The last scion of the house who attained political eminence was **Matthieu, Duc de M.** (born 10th July 1776), who, escaping destruction at the Revolution, lived to become Foreign Minister under Louis XVIII. He died at Paris, 24th March 1826. See Sismondi's *Histoire des Français* (vols. iii., v., vi., xv.-xxii.); and Kitchin's *History of France* (vol. ii. 1877).

Montoro, a town of Spain, province of Cordova, 25 miles E. by N. of Cordova city, with which it is connected by rail. It lies on a steep ridge on the left bank of the Guadalquivir, which is here crossed by a lofty four-arched bridge. Olive oil is largely manufactured, and woollen and earthenware industries exist. Pop. 10,500.

Montpelier, the capital of Vermont, United States, on the Onion River, 205 miles N.N.W. of Boston by rail. It has several churches, a Methodist Seminary and Female College, two banks, and five weekly newspapers. The State Capitol at M. is one of the finest in the U.S. There is a considerable general trade. Pop. (1870) 3023.

Montpellier, a town in S. France, department of Hérault, on the river Lez, 9 miles from the Golfe du Lion by the Grave Canal, and 30½ miles S.W. of Nîmes by rail. It is a picturesque

town, built on a high hill standing in a plain covered with fruit-gardens and country-houses, and commanding a beautiful view towards the sea, Mont Ventoux, and the Pyrenees. M. has a large esplanade shaded with trees, a triumphal arch, called the *Porte de Peyrou* (1691-92), leading to the Corinthian colonnades of the *Place de Peyrou*, from which extends for 1½ miles an aqueduct, built 1753-66; a fine hospital, a bourse, palais de justice, and cathedral of St. Peter; a university (1196), with a famous school of medicine founded in the 12th c. by Arabian physicians, and a library of 50,000 vols. and 600 MSS.; a botanical garden (the oldest in France); an observatory, and a town library of 30,000 vols. There are also twenty-one churches (one Reformed), the Fabre picture gallery, and numerous educational and charitable institutions. M. has large and various industries. It manufactures corks, candles, soap (especially in the neighbouring Villodève, to £400,000 yearly), silks, woollens, liqueurs, chemicals, and has a trade in brandy, wine, liqueurs, silk-stuffs, and articles of luxury. Pop. (1872) 57,727.

Montreal, a city of the Dominion of Canada, in the province of Quebec, 200 miles N.E. of Lake Ontario, 180 S.W. of Quebec, and 335 N. of New York. It stands on an island of the same name, 30 miles long by 10 broad, formed by the confluence of the Ottawa with the St. Lawrence, which is here spanned by the tubular Victoria Bridge of the Grand Trunk Railway (1854-59), with 24 piers 60 feet high, and a total length of 9184 feet. Behind the city rises the wooded Mont Royal (750 feet), so named by Cartier, and whence comes the modern name of M. Of 64 churches the finest are the Catholic parish church of Notre Dame (1824-29), with six towers, two of them rising to 213 feet; and the Anglican Christ Church Cathedral, with its spire 224 feet high. Besides the McGill University (founded 1811) and University of Bishop's College (1853), the Catholic Montreal College (1773), and St. Mary's College (1852), the College of Physicians and École de Médecine, there are 32 educational institutions. M. has 8 daily, 9 weekly, and 13 other newspapers and periodicals. The harbour, 90 miles above the influence of the tide, and generally frozen over from December to April, extends for 3 miles, and can now admit ships of 1800 tons burden. It is lined for one mile with limestone wharfs. In 1873 there entered 422 vessels, of 307,453 tons; and cleared 527, of 354,911 tons. The value of imports in the same year was \$44,320,646; and of exports (grain, timber, furs, fish, &c.), \$19,679,118; while the customs revenue for 1870 amounted to \$4,128,052. By the Grand Trunk, Megantic, Intercolonial, and other railways, M. is connected with every part of Canada and the United States; and the Allan mail steamers ply weekly between Liverpool and M. in summer, and Liverpool and Portland during the winter months. M. is at once the commercial capital and the metropolitan seat of the Dominion, and till the reduction of the troops in 1871 was the military headquarters of British N. America. It returns three members to the Dominion House of Representatives, and three to the Quebec Legislature. Pop. (1871) 107,225, of whom 77,980 were Roman Catholics, chiefly French Canadians. Jacques Cartier discovered in September 1534 an Indian village, Hochelago, near the site of which thirty-five French settlers founded the town of Ville Marie or M., May 13, 1642. Captured by 17,000 English under General Amherst, September 8, 1760, M. witnessed the rising of the 'Sons of Liberty' (1837), was the seat of Government (1844-49), and in 1875 was the scene of a serious bread riot and disturbances arising from the refusal of the Catholic authorities to inter Joseph Guibord, a member of the proscribed L'Institut Canadien, in consecrated ground.

Montrose (Gael. *Monrass*, 'the marshy peninsula'), a seaport and royal burgh of Scotland, in Forfarshire, situated on a peninsula at the mouth of the S. Esk, which here expands into an almost land-locked basin, 35 miles N.W. of Dundee by rail. It is a thriving seat of the linen industry, and has one of the best harbours on the E. coast of Scotland, there being 18 feet of water on the bar at lowest tides. The chief buildings are the town-hall, the parish church (1791), and the Royal Lunatic Asylum (1868), erected at a cost of £30,000. There are statues of Sir Robert Peel and of Joseph Hume, who was born here in 1777. Between the town and the sea extensive links or downs extend to the N. M. Basin, which forms a sort of roadstead to the port, 7 miles in circumference, is shallow, and partly left dry at low tide. The channel by which the waters

find exit is impeded by the island of Rossie or Inchbrayock, and is crossed from M. by a handsome suspension-bridge, 432 feet long, constructed (1828-29) at a cost of £20,000. Communication with the mainland in the S. is completed by a small draw-bridge. In 1870 the Board of Trade erected the Scurdyness Lighthouse (cost £2700) at the mouth of the river, with a light visible for 20 miles. M. has (1877) four large flax-spinning mills, employing over 2000 hands. Shipbuilding has greatly decreased of late years, but there is a considerable industry in timber-sawing. In 1876, there entered and cleared the port 790 vessels of 114,562 tons. M., with Arbroath, Forfar, and Bervie, sends one member to Parliament. Pop. (1871) 15,720. Chartered by David I., M. is the port from which Sir James Douglas sailed for the Holy Land with the heart of Bruce in 1330. The famous Marquis of M. was born here in 1612. M. was the first place in Scotland where the Greek language was taught, and its educational reputation has been well sustained by its modern academy.

Montrose, James Grahame, First Marquis of, son of John, fourth Earl of Montrose and Lady Margaret Ruthven, was born, it is believed, in the town of Montrose in 1612, went to the University of St. Andrews in 1627, and married Magdalene Carnegie, daughter of Lord Carnegie of Kinnaird, about three years afterwards. After a residence at Kinnaird Castle he sought a larger experience of life, when he attained his majority, by travel. In France, his passion for arms induced him to enlist as captain in the domestic service of Louis XIII. He appeared at the English court in 1636, but for some reason now unknown Charles I. overlooked or even offended him. The result was that M., returning to Scotland in the following year, threw himself with enthusiasm into the Covenanting cause, and his name heads a project for a 'contribution' in February 1638. In the same year he was appointed chairman of a committee which proceeded to Aberdeen in order to force the people to sign the Covenant. But the adherents to the Covenant being few, M. put himself at the head of a small army carrying the ensign, *For Religion, the Covenant, and the Country*, and in May 1639, though no plundering was allowed, he levied an impost of 10,000 marks from the people of Aberdeen. Returning to Aberdeen later on in the year, he found the Cavalier leaders dispersed, and determined to destroy their strongholds, beginning with the Tower of Gight, but owing to false information and the approach of the Earl of Aboyne, he retreated to Edinburgh. On the 15th of June at the Raid of Stonehaven, and on the 19th at the Bridge of Dee, he again overcame the Cavaliers and established the Covenant. The same autumn M. met the king at Berwick, and though on the 20th August 1640 he led a contingent of the Covenanting army across the Tweed at Coldstream against the royal forces, some said 'that on this occasion the exhibition of ardour was but a mask to hide treachery.' And it is certain that he had already been in correspondence with the king. M. was therefore ordered to be committed to Edinburgh Castle (24th July 1641) on the charge of furthering the 'Cumbernauld Band,' a covenant which was supposed to thwart the cause of the original one. An inquiry into that and an allegation that M. plotted against the life of Argyll, ended in his imprisonment till 1642, after which he joined the cause of the king. The year 1644-45 represents the most brilliant period of M.'s career. It was his duty to raise the Highlands, so that the Scotch army in England should be recalled. Making his way in disguise to Blair Atholl, he unfurled his standard and sent round the 'fiery cross.' With 1200 Irishmen and the fighting men of the clans who had rallied round him, he advanced to Perth and routed the mob who came out to meet him at Tippermuir (September 1, 1644). He then marched N. to Aberdeen, met the Covenanting army W. of the city, and after two hours' fighting dispersed it. In winter, being reinforced by Macdonald of Kolkitto, M. made a swift and successful raid upon Argyll and drove him from Inverary, defeated him at Inverlochry (February 2, 1645), pillaged Elgin and Banffshire, and (April 3) entered Dundee in triumph, winning victories during the next two months at Auldearn and Alford, and on August 6th at Kilsyth. M. was now appointed Viceroy of Scotland, but in travelling to recruit his army from the Borders, he was surprised at Philiphaugh by a powerful body of cavalry under David Leslie, and utterly crushed. M. escaped from the field with a few followers. A new effort to arouse the clans failed, and Charles in the same year withdrew

M.'s commission as lieutenant-general, and (3d September 1646) he sailed for Norway. Being urged in Holland by the Prince of Wales (Charles II.) to fight for the royal cause, he planned an invasion of Scotland, reached the Orkneys with 1700 men (March 1650), passed to the mainland, but evoked no enthusiasm, and at Invercarron, on the northern border of Ross-shire, was defeated by Colonel Strachan. Shortly after, he was captured by Macleod of Assynt, sent to Edinburgh and executed, 25th May 1650. M. was a man of taste and learning as well as a warrior by natural genius. His victories were often softened by clemency, and his own death was glorified by an exhibition of unflinching manliness. See Burton's *History of Scotland* (vols. vi. and vii.); and Mark Napier's *Memoirs of the Marquis of M.* (2 vols. Edinb. 1856).

Monts-de-Piété (Ital. *Monti di Pietà*, i.e., 'charity-banks'), institutions for lending small sums of money to the poor at low interest on movable property deposited as security. The first of these was founded at Perugia in 1440 by the exertions of a Franciscan friar named Barnaba di Terni, with the object of protecting the poor from the avidity of the Jewish money-lenders. The good resulting from its gratuitous loans gained the praises of the clergy, and led to the establishment of Monts-de-Piété in Orvieto (1445), Viterbo (1471), Bologna (1475), Parma (1488), Padua (1491), Florence (1492), Milan (1496), Turin (1519), and Rome (1539). They gradually extended to other countries. The first in Germany was founded at Nürnberg in 1498, in Holland at Amsterdam in 1578, in Belgium at Brussels in 1618, and in France at Avignon in 1577. The M.-de-P. of France, suppressed during the first Revolution, were re-established in 1805, and re-organised in 1852. They are 44 in number, annually receive pledges representing a value of two million pounds, and can dispose of a capital equal to one and a half millions. Four of them lend gratuitously, the others at from 4 to 12 per cent. Of these 24 devote their profits to increasing their capital, and 13 to the funds of hospitals.

Montserrat (Lat. *Mons serratus*), a mountain in N.E. Spain, province of Catalonia, 25 miles N.W. of Barcelona. It consists of breccia-like rocks of Tertiary age, resting on cretaceous formations, and rises from rich, green country, an isolated ridge 4060 feet high, stretching from E. to W. Its sides are everywhere cleft by deep ravines covered with evergreen shrubs and trees. On the W. side it falls perpendicularly to the river Lobregat, in walls 985 to 2130 feet high, topped with fantastic peaks. The view from the highest summit takes in all Catalonia. Seen from Barcelona, M. seems a tabular colossus whose crest is split into numberless peaks like the edge of a saw (*serra*). Legend tells that it was so riven at the Crucifixion. Twelve of the highest summits bear traces of hermits' dwellings; and on the E. side, at a height of 1350 feet, is a partly-ruined Benedictine monastery, which was the centre of the Carlist insurrection in 1827.

Montserrat, an island in the W. Indies, one of the Lesser Antilles, belonging to Britain, 3½ miles N.W. of Guadaloupe, and 28 S.W. of Antigua. Area 47 sq. miles; pop. (1871) 8693. Only one-third of the surface is under cultivation. The exports are sugar, rum, molasses, cotton, arrow-root, and tamarinds. In 1874 the revenue of M. was £5106; expenditure, £5497; the total tonnage of vessels entered and cleared was 13,289 tons (British, 12,171 tons); the value of total imports £23,958 (from the United Kingdom, £7095), and exports £33,079 (to the United Kingdom, £30,926, of which sugar was £23,508). The chief town is Plymouth, on the S. coast.

Monza, a town of Italy, in the province of Milan, on the Lambro, 8 miles N.E. of Milan by rail. The *Modica* of Theodor, who built a *palatium* here, M. has a cathedral, erected in the 14th c. by Campione on the site of the basilica of Theodolinda (595), which contains the tomb of that Lombard queen, and the Iron Crown (q. v.), restored by the Austrians in 1866. Other buildings are the Church of the Madonna di Tirano, containing frescoes by Luini and Ferrari, the Lyceum, the Broletto or Town-Hall, once the residence of Friedrich Barbarossa, and the Palazzo Imperiale, with a park 9 miles in circumference, and the finest gardens in Italy. There are manufactures of cloth, hats, and leather. Pop. (1874) 25,288.

Mood'y, Dwight Lyman, born at Northfield, Massachusetts, February 5, 1837, worked as a farm labourer till he was

seventeen, and in 1856 came to Chicago. Here he opened a Sunday School for 1000 children, and became pastor of a Congregational church, and here, in 1871, he was joined by **Ira David Sankey**, who, born at Edinburg, Pennsylvania, August 28, 1840, had been in business at New Castle since 1855. Coming to Great Britain in 1873, the two held a series of gigantic revival meetings at Edinburgh, Glasgow, Dublin, London, and other cities, M. preaching, and S. singing the well-known hymns that go by his name. Their first audience at the Agricultural Hall, Islington, was estimated at upwards of 21,000, and the total expenses of the mission amounted to £28,396, of which a deficit of £138 was left by public contributions. Since their return to America (1875) they have continued their evangelistic work at Chicago, New York, and other places.

Mooltan (*Mullān*), the chief town of the division and district of the same name, in the Punjab, British India, 3 miles from the left bank of the Chenab, and 164 miles S.W. of Lahore. Pop. (1868) with suburbs, 56,826. It is an ancient city, which has suffered much in war. The neighbourhood is covered with ruins, and to the N. is the magnificent shrine of the Mohammedan martyr, Sham Tabrezi. In 1818 M. was captured from the Afghans by Runjeet Singh, who is said to have acquired a booty of four millions sterling. In the second Sikh War (1848-49) M. was bombarded and captured (Jan. 1849) by General Whish, and the fort subsequently destroyed. An obelisk preserves the memory of those who fell in the Sutlej campaigns. M. is a great centre of trade. It is at present the terminus of the Scinde, Punjab, and Delhi Railway, and the point of departure for the Indus flotilla, under the management of the same railway company. The local trade in 1873-74 was estimated at £314,436 for imports, and £193,871 for exports. In 1874 the flotilla steamers carried to and from M. upwards of 16,000 tons, valued at more than one million sterling. In 1876-77 European piece-goods to the value of £45,000 were imported by rail from Calcutta. There are special manufactures of carpets, silks, and silver vases.—The district of M. lies between the Chenab and Sutlej rivers, and borders on the native state of Bhawalpor. Area 5927 sq. miles; pop. (1868) 471,563. There are thirty-nine canals, with an aggregate length of 632 miles, of which only 11 miles have been added since the commencement of English rule. They irrigate 250,000 acres, and are repaired by statute labour. By their means the crops were saved during the drought of 1877. The staple crop is wheat; fruits and vegetables are also abundant. See Sir H. Edwardes' *Year on the Punjab Frontier*.

Moon, The, is the nearest heavenly body to our earth, round which it revolves at a mean distance of 238,800 miles, in an elliptic orbit of mean eccentricity .0549. It shines solely by reflected light, derived chiefly from the sun. Consequently the amount of surface which is visible to us depends upon the relative positions of the sun, earth, and M. At full M., when the M. and sun are in opposition, i.e., on opposite sides of the earth, the whole illuminated hemisphere is seen. At new M. again, when sun and M. are in conjunction, the illuminated hemisphere is wholly turned from us, and therefore there is nothing seen. In certain circumstances, however, the dark body of the M. is seen projected on the bright disk of the sun, occasioning a solar eclipse (see ECLIPSES). Such a phenomenon would occur at every new M. if the M. revolved in the plane of the ecliptic. In virtue, however, of the inclination of the plane of its orbit to the ecliptic (the mean value is 5° 8' 47" 9), our satellite is usually out of the line of the earth's radius vector, and eclipses only occur when it happens to be at or near its nodes or points at which its orbit intersects the ecliptic. The two nodes diametrically opposite each other are constantly changing their position, completing a single revolution in 6793.391 days; and they must be within a certain definite distance from the positions of new or full M. before a solar or lunar eclipse can take place. Shortly after new M., our satellite is seen as a thin crescent setting in the W. very soon after the sun. Frequently, however, the dark body of the M. is faintly illuminated by light reflected from the earth, giving rise to the familiar phenomenon popularly known as the 'old M. in the new M.'s arms.' On each successive night the visible crescent increases, and the time of setting gets later, until after a week's time it has reached the *half-M.* phase—the end of its first quarter. In another week's time it attains *full M.*—the end of the second quarter—after which it diminishes through its decreasing phases, rising before the sun at intervals which

gradually grow shorter and shorter till the time of new M. comes round again. It takes a mean period of 29'530589 days to complete this cycle, which is the *synodical month or lunation* (see MONTH). The time of the M.'s rotation on its axis is the same as its mean sidereal revolution round the earth—27'321661 days. Consequently the same face is always presented towards the earth; and we never see the other hemisphere, except when certain irregularities of motion permit us to catch a glimpse of the thin strips that lie just round the visible edge (see LIBRATION). Other lunar inequalities are discussed under LUNAR THEORY. The M. is 2165 miles in diameter, has a mean density of 3'37 (that of water being 1), and has a mass $\frac{1}{81}$ th part of the earth's. Under the telescope the surface of the M. presents a very diversified appearance. Plains, mountain chains, ridges, craters, valleys, clefts, and faults are plainly recognisable. There is no positive evidence of the existence of water or an atmosphere, nor sign of life of any kind. Recently, however, speculation has been rife as to the possibility of the M. being the habitat of living creatures. Though the eminent astronomers Beer and Mädler regarded the surface of the M. as not liable to any physical changes, recent observations by Schröter, Webb, Birt, and others, indicate changes of aspect too marked to be explained solely as due to differences of illumination. Neison in his recent work (*The Moon and the Condition and Configuration of its Surface*, 1876), follows out Mattieu Williams' suggestion of the universal atmosphere, condensed by gravitation on the surfaces of the various members of the solar system. The condensation will of course depend upon the mass of the body; and calculation gives to the M. an atmosphere whose pressure does not exceed $\frac{1}{81}$ th part of that of our earth's. This extreme rarity may account for the absence of any positive evidence, such as the refraction of stellar light during occultation of a star; and it suggests a reason why water is not visible. The pressure is not sufficient to permit of the existence of water in the fluid state. It may, however, be present in the solid or gaseous state. Some observers, indeed, have described peculiar blue-tinted appearances on the line of separation between light and darkness, which bear resemblances to glaciers. As the sun's heat gets stronger with advance of the lunar day, these glaciers may be volatilised into vapour, to re-condense when the long night comes round again. Life may in such circumstances be possible—the animals hibernating through fourteen days of darkness, enclosed in a shell of ice. There seems no doubt, however, that at one time the M. was the seat of extensive volcanic action. The average height of the mountains is 5 miles; the craters and circular ranges, a marked feature of the M., vary in diameter from a few hundred feet to fifty or sixty miles; while the clefts, the most perplexing of all lunar features, attain a length of 300 miles. The explanation of the physical origin of these is still far from complete, since in our earth we have no truly analogous appearances to guide us. The coincidence in time between the periods of axial rotation and orbital revolution has been explained as due to the retarding effect of tidal friction at a time when the surface of the moon was molten. From observations of one of Jupiter's satellites, this same peculiarity is supposed to extend to all satellites, and to have been produced by the same cause. Under TIDES, an important part of the mutual action of the earth and M. is considered. Of late years, much interest has been revived in the M., and photography has rendered invaluable service to the delineation of its surface. Excepting Neison's book above mentioned, which is a valuable compendium of recent observations, the latest work on the subject is *The Moon considered as a Planet, a World, and a Satellite*, by Nasmyth and Carpenter (1874).

Moon, Mountains of the (Arab. *Jebel-el-Komr*), from the days of Ptolemy supposed to be a lofty range crossing the continent of Africa from E. to W. in the region of the equator, has been identified by Beke with the southern continuation of the Abyssinian system, which traverses the country of the Gallas and Sudheli, passing the equator half-way between the coast and the great central caves. To the S. of the equator it rises in the great peaks of Kenia and Kilimandjaro, with heights, estimated at 12,000 and 20,000 feet respectively.

Moon-Blindness, or **Nocturnal Amaurosis**, is a disease which, though rare in this country, is by no means uncommon in warm climates, and more especially among seamen. The first attack generally excites great alarm, being unaccompanied

with any premonitory or constitutional symptoms. M.-B. probably depends on some peculiar state of the retina, rendering the eye insensible except to light of a certain degree of intensity. The disease is generally curable.

Moon'shee (*Mūnshī*) a word of Arabic derivation, meaning a 'writer or secretary.' It is universally applied by Europeans in India to teachers and interpreters of Persian or Hindustani.

Moonsiff (*Mūnsif*), a word of Arabic derivation, meaning 'equitable or just.' It is used throughout India for the native judge in the lowest civil courts of first instance, whose limit of jurisdiction varies in the different Provinces.

Moon'stone. See FELSPAR.

Moore, John, M.D., the son of an Episcopalian clergyman, was born at Stirling, 1730, studied medicine at Glasgow University, and in 1747 obtained an appointment in one of the military hospitals in Flanders. After the Peace of Aix-la-Chapelle he went to Paris as surgeon in the household of the English Ambassador, Lord Albemarle. Two years later he returned to Scotland, and commenced practice in Glasgow. He afterwards accompanied the Duke of Hamilton on a continental tour, and on his return settled in London, where he published *A View of Society and Manners in France, Switzerland, and Germany* (1779), followed by *A View of Society and Manners in Italy* (1781). In 1789 appeared his once popular novel *Zeluco*, and in 1795 *A View of the Causes and Progress of the French Revolution*. This was followed by the novels *Edward and Mordaunt* (1800), which now lie buried in oblivion. His last work was an edition of Smollett, with a memoir. M. died at London, 20th Feb. 1802. Anderson edited his works in 7 vols. with memoir (Edinb. 1820.)

Sir John M., a celebrated and popular general, the son of the preceding, was born in Glasgow, November 13, 1761. In 1776 he joined the 1st Regiment of Foot, of which he became lieutenant-colonel in 1790. He distinguished himself at Corsica in 1794, acted as brigadier-general in the W. Indies in 1795, and was subsequently appointed governor of St. Lucie. M. assisted in suppressing the Irish Rebellion in 1797, took part in the ill-fated expedition to Holland in 1799, and served in Egypt in 1800. He was second in command in Sicily in 1802; after which he was charged with an abortive expedition to Sweden. In 1808 M. received the command in chief of the army sent to Portugal to aid the Spanish resistance to the French. He pushed forward from Salamanca on 12th December with 25,000 men to attack Soult's army, and had defeated the enemy's cavalry at Salagun, when he learned that Madrid had fallen, and that Napoleon was advancing against him with greatly superior forces, while Soult menaced him from another point. Thereupon, across the snows of a mountainous region, M. made a masterly retreat of 200 miles to Coruña, which he reached January 13, 1809. There he embarked his sick and artillery, and without cannon defeated Soult's army, January 16th. He died on the field from a cannon-shot. Monuments are erected to his memory in St. Paul's Cathedral and at Glasgow. Ever foremost in the post of danger, M. was severely wounded on many a well-fought field. His dauntless intrepidity inspired his soldiers with affectionate enthusiasm. Called on to lead one forlorn hope after another, his patience never wearied and his courage never failed. See J. C. Moore's *Life of Sir J. M.* (2 vols. 1834), and Napier's *History of the War in the Peninsula* (1832).

Moore, Thomas, was born of Roman Catholic parents in humble circumstances, at Dublin, 28th May 1779. His first teacher was Samuel Whyte, who also taught Sheridan. Early noted as a good actor and mimic, M. contributed verses to the *Dublin Magazine* when fourteen, and in 1798 took the degree of B.A. at Trinity, having acquired more than a fair reputation as a classical scholar. At this period of his life, he was an ardent democrat and Irish 'patriot'—in verse. Having gone to London to study law in the Middle Temple, he published by subscription a translation of Anacreon's odes, and soon forgot the woes of his country in a whirl of dissipation. In 1801 he put forth the *Poetical Works of the late Thomas Little, Esq.*, which were well received, though reviewers fell foul of their occasional indelicacy. Lord Moira appointed M. registrar to the Admiralty in Bermuda, whither he repaired in 1804; but finding a good climate could not be enjoyed on a poor salary he returned in three months, travelling through America, and on his arrival in London, published his *Odes and Epistles*. He next engaged in a con-

genial and patriotic task, furnishing appropriate songs to the most beautiful of his country's national airs. The *Irish Melodies* appeared at intervals between 1807 and 1834. M. was now one of the idols of society, so little and rosy in appearance that he could only be likened to Cupid, so witty a versifier that his newspaper squibs were city talk, and a morning's work earned a small income, so good a story-teller and musician that he made the lords he loved so dearly laugh and cry by turns of an evening. In 1812 appeared *Intercepted Letters, or The Twopenny Post Bag*, by Thomas Brown, jun., in which his light and laughing satire attains its most delicate piquancy. Five years later he published *Lalla Rookh*, a gorgeous Eastern romance which dazzled the public for a season, but is now fast becoming unreadable, in spite of its various lore and glittering fancies. It lacks passion, pathos, and the shaping spirit of imagination. *The Fudge Family in Paris* (1818) was once amusing. In 1819 he visited Lord Byron at Venice, and formed the friendship which led to his editing *The Letters and Journals of Lord Byron, with Notices of his Life* (1830), a work full of interest, but too copious, and too lenient in its criticism. Of his later works the most elaborate are *The Loves of the Angels* (1823), *The Life of Sheridan* (1825), *The Epicurean* (1827), *Life and Death of Lord Edward Fitzgerald* (1831), *Travels of an Irish Gentleman in Search of a Religion* (1833), and *History of Ireland* (1835). Literature proved lucrative to M., but he remained a spendthrift to the end of life. In 1835 a pension of £300 a year was conferred on him, and in 1850 his wife received another £100. M. died at Sloperton Cottage, near Devizes, February 26, 1852. Most of his work is passing away, and will soon be forgotten; but his *Irish Melodies* are imperishable. They are not all good; many are even trivial and poor, but the finer ones have a radiant grace and vivacity of sentiment, a starry sparkle of wit, and a faultless finish of diction that must yield a perpetual pleasure. See his *Memoirs, Journals, and Correspondence*, edited by Lord John Russell, in 8 vols. (Lond. 1852-56); and *M.'s Hitherto Uncollected Writings*, edited by R. H. Shepherd (Lond. 1877).

Moorfowl, a name given to the Red Grouse or Red Ptarmigan (*Lagopus Scoticus*), a bird belonging to the order *Rassores*, and to the family *Tetraonidae*. The M. appears to be confined in its distribution to Britain. It is of a chestnut-brown colour, variegated with black, the under parts being light-red. The legs and toes are feathered. The eye is surmounted by a crescentic patch of scarlet-coloured skin. The average length of this bird is 16 inches. Its nest is placed on the ground, the eggs numbering from ten to fifteen.

Moorhen. See GALLINULE.

Moorings (Dutch, *marren*, 'to fasten'; Fr. *amarrer*; cf. Eng. *marline*, and Lat. *mora*, 'delay'), the apparatus to which a ship is fastened when stationed in a harbour. This either consists of two anchors fixed in nearly opposite directions, by one or both of which the vessel may *ride*, or of weights (called *mooring-blocks*) connected by chains sunk in the harbour.

Moorish Architecture. See SARACENIC ARCHITECTURE.

Moors (the *Maurusioi* of Greek, and *Mauri* of Latin writers), an African race, akin to the Numidians, who inhabited Mauritania (q. v.), and have their modern descendants in the Amazirghi (cf. *Masues* in Herod. iv. 191) branch of the Berbers. They figure first in history in the Punic and Jugurthine Wars, and sided with Genseric, the Vandal invader of Northern Africa (429 A.D.). Having shared in the reduction of the Vandal kingdom by Belisarius (533), the M. were next conquered and converted to Islam by the Arabs (698). Many of them followed their conquerors into Spain (709), and others were invited over to co-operate against the Christians (1091). In 1225 was founded the Moorish kingdom of Granada (q. v.), the capital of which, according to a 14th c. chronicler, had a pop. of 200,000. On the capture of that city in 1492, such of the M. as refused to accept baptism were expelled from Spain, while the remnant that complied—known as *Christianos Moriscos*, or simply *Moriscos*—were driven by cruel persecutions to revolt (1568-70), and were finally banished by Philip III. in 1609.

The terms *Moor* and *Moorish* have also been used as synonymous with *Arab*, *Saracen*, or even *Mohammedan*. Hence 'morris dance' and 'nine men's morris' in English; the frequent occurrence in France of such words as *Forêt des Maures*, *Mont*

Maure, &c.; and Colebrooke's application of the term '*M.* language' to Hindustani.

Moorshed'abad (*Mūrshīdābād*, 'the city of the priest,' originally called *Makrūdābād*), the principal town in the district of the same name, Bengal, British India, mostly situated on the left bank of the Bhagirutti, the first offshoot of the Ganges, 124 miles N. of Calcutta. Pop. (1872) 46,182. The last Mohammedan capital of Bengal, from 1704 to 1772, and still the residence of the Nawab, whose palace, erected in 1840, at a cost of £160,000, in the Italian style, and most handsomely furnished, is conspicuous from the river. It is now a decaying city, but was described by Lord Clive in 1759 as being as extensive, populous, and rich as London. The buildings are mean, except the palace, the Imambara, and the Nizamut College. The manufactures are ivory carving, gold and silver embroidery, silk-weaving, musical instruments, and pipes. The city is called after the Nawab Moorshed Cooly Khan, its second founder, and it was for some years the British capital of Bengal, before the offices of government were fixed at Calcutta. The Nawab Moorshed, sometimes known as Jaffier Khan, was the most skilful of all the administrators of Bengal under the Moguls. By birth a Brahmin, he was brought up as a slave in Persia, and exhibited the characteristics of a renegade. He ruled from 1704 to 1725. The present Nawab of M., whose family enjoy a pension of £150,000 a year, resides in England near Brighton. —The district of M., which lies between the river Ganges and the hills of Beerbhum, and is bisected by the Bhagirutti, has an area of 2578 sq. miles; pop. (1872) 1,353,626. The crops are rice, pulses, and wheat; silk and indigo are declining manufactures. The towns are Berhampore, the civil and military headquarters; Cossimbazar, now a ruinous swamp, but the former site of many European factories; and the marts of Jungipur, Jagunge, and Dhulian. The trade by river and rail is considerable, and is in the hands of Jain merchants. In the year 1876-77 the exports were valued at more than a million sterling, chiefly silk, rice, pulses, wheat, indigo, and oil-seeds; the imports at £740,000, chiefly piece-goods, salt, sugar, and tobacco.

Mooruk' (*Casuarina Bennettii*), a species of Cassowary (q. v.), discovered by Devlin about 1857, and described by Dr. Bennett. It occurs in New Britain. Its height is 3 feet or more, and its colour is reddish, mixed with black. The naked skin of the neck has iridescent hues. The head has a hard, black, and shining horn-plate. Each foot has three toes, the claw of the inner toe being three times the length of the others. The voice is described as a whistling sound. The wing has four spinous processes, while the nearly-related cassowary has five. The M. becomes very tame in captivity, and appears to possess a high degree of intelligence.

Moplahs, a tribe of Mohammedans on the Malabar or W. coast of S. India, numbering about 600,000. They are an Arab race, recruited by converts from Hinduism during the persecution of Hyder Ali and Tippu. Hardworking cultivators and enterprising traders, they are liable to serious outbreaks of religious fanaticism. In 1855 the Collector of Madura was murdered, and again in 1873 nine fanatics rushed upon the bayonets of a detachment of European troops, who are always stationed in the district.

Mo'ra (*M. excelsa*) is a gigantic timber-tree of British Guiana and Trinidad, belonging to the *Casalpinieæ* sub-order of *Leguminosæ*. The tough and close-grained wood is imported for ship-building purposes, for which it is admirably adapted. The bark is astringent and suitable for tanning, and the large seeds are used by the Indians for food in times of scarcity.

Mora'cese, a natural order of dicotyledonous trees, shrubs, and herbs, sometimes climbers, having a milky juice, and closely related to the Nettle family. The greater number of species are those of the genus *Ficus*—the fig, india-rubber, banyan, &c., and another important member of the order is *Maculura tinctoria*, the Fustic.

Morad'abad (*Mīrādābād*), the chief town of the district of the same name in the N.W. Provinces, British India, on the right bank of the Ramgunga river, and a newly opened station on the Oude and Rohilkund railway, 100 miles N.E. of Delhi, and 838 N.W. of Calcutta. Pop. (1872) 62,417. The cantonments lie W. of the town. During the Mutiny of 1857, dis-

cipline and order were preserved for some time by the personal exertions of the Judge; and finally, after the outbreak at Bareilly, the Europeans safely escaped either to Meerut or Nyni Tal. The district of M., which is bounded N. by the hills of Kumaon, has an area of 2272 sq. miles; pop. (1872) 1,122,437. It is irrigated by small canals; the crops are wheat, millets, rice, Indian corn, sugar-cane, and cotton. Oil-seeds, sugar, and raw cotton are exported by rail, and piece-goods imported.

Moraine. See GLACIERS.

Moralities. See MYSTERIES, MIRACLE PLAYS and MORALITIES.

Morals. See ETHICS.

Morano, the anc. *Muranum*, a town of S. Italy, province of Cosenza, on the W. side of Monte Pollino, 35 miles N. of Cosenza, near a ruined town and castle; has silk and cotton industries. Pop. (1874) 8910.

Morat (Ger. *Morten*), a Swiss town in Freiburg, on the Lake of M., which is 6 miles long and 3 wide, and is connected by the River Broye with the Lake of Neuchâtel, 7 miles distant to the W. It is a wealthy town, and its narrow arcaded streets are overshadowed by an old castle which, with a garrison of 15,000 Bernese, resisted for ten days the artillery of Charles of Burgundy. The famous battle of M., the bloodiest of the three contests, in which the Duke lost his 'Gut, Muth, and Blut,' was fought 22d June 1476. The Bernese, with allies from the Rhine cities, numbered 34,000, or 6000 less than the enemy; yet the Burgundians were defeated with a loss of 15,000 men, and of all their ammunition and baggage. A marble obelisk, 65 feet high, was raised on the battlefield in 1822.

Moratin, Leandro Fernandez de, a Spanish poet and dramatist, the son of Nicolas Fernandez de M., also a dramatist (1737-1780), was born at Madrid, March 10, 1760. His amusing comedy, *El Viejo y la niña*, was first acted in 1790. From 1792 to 1794 he travelled throughout Europe for the purposes of dramatic study. After his return to Spain he produced *El Baron* (1803), *La Mogigata* (1804), *El si de las Niñas* (1806, one of his best plays), several other comedies, translations from Shakespeare and Molière, and *Lecton Poetica*, satirical pieces. The fear of the Inquisition induced him to abandon writing for the stage, and he thereupon began his great historical work, *Origenes del Teatro Español*. M. became chief of the Royal Library under Joseph Bonaparte. On the return of Ferdinand in 1814, he fled to Paris, where he died, 21st June 1828. M. is called the 'Spanish Molière,' but the flattering phrase excites a smile. His *Obras Completas* were published at Madrid (6 vols. 1830-31); a good edition by Revadeneyra in 1848. A French translation appeared in 1855. See *Modern Poets and Poetry of Spain*, by James Kennedy (Lond. 1852).

Morava (Slav. 'border river,' Ger. *March*, the Roman *Marus*), the chief river of Moravia, to which country it gives name. It rises in the Schneeberg, on the S. frontier of Silesia, flows in a southerly direction, receives the Thes, Oskava, Taya, &c., and joins the Danube 25 miles below Vienna after a course of 212 miles, of which only 50 are navigable. The boundary between Lower Austria and Hungary in its lower course, its valley has been the scene of many battles, including Aspern, Wagram, and Essling.—Another M. (*Marchus*), nearly 200 miles long, rises in Bulgaria, flows N. through Servia, and joins the Danube 45 miles below Belgrad.

Moravia (Ger. *Mähren*), a crown-land of Austria, is bounded N. by Silesia and Bohemia, W. by Bohemia, S. by Lower Austria, and E. by Galicia and Hungary. Area, 8583 sq. miles; pop. (1869), 2,017,274. M. lies in the angle formed by the separation of the Carpathians and the Sudetic range, and is enclosed on the W. by a lofty plateau. It descends from the N.E. in three mountainous terraces, respectively 2000, 1500, and 1100 feet high, till it reaches the open plains in the S.W., watered by the Morava and its affluents. M. is singularly fertile and well cultivated, the rich valleys and plains yielding abundance of grain, beet-root (11,545,973 cwts. in 1871), hops, hemp, flax, fruit, and wine (3,273,147 gallons). Of the surface one-half is arable, one-fourth under forest, one-tenth in pasture, and one-twelfth occupied by gardens. There is a considerable mining industry in the mountain districts, and the

principal minerals are iron, coal, graphite, and meerschauum. A large proportion of the inhabitants are engaged in the rearing of horses (in 1872, 118,469), cattle (537,305), sheep (323,503), goats (541,536), swine (161,419), bees (68,865 hives), geese and ducks (14,000,000), and hens (7,000,000), and there are manufactures of beet-sugar, linens, cottons, woollens, tobacco, glass, and machinery. The inhabitants are Czechs and Poles, to the number of 1,500,000; the Germans amount to 519,400. In the S. there is a colony of some 1580 Croats. All the people are Roman Catholics, with the exception of 53,000 Protestants and 42,000 Jews. Olmütz was formerly the seat of a university, and Brünn has a technical institute. Brünn is the capital, and other towns are Olmütz, Iglau, Zwittau, and Prossnitz. M. has an important transit trade, which is carried on over excellent roads and extensive railways.

History.—An independent Slavic kingdom in the 9th c. and named from the river Morava (Slav. 'border river'), M. originally included the N. part of Hungary. It rose to its greatest power under Zwentibold, who, however, was defeated and deprived of part of his territory by the Magyars under Arpad in 894. The land was Christianised by Cyril, made tributary to Bohemia 1029, and raised into a markgrafsdom by Friedrich I. in 1182. By succession it passed with Bohemia to Austria after the death of Ludwig II. at the battle of Mohacz, 1526. It has been a separate crown-land since 1849. See the works of Wolny (6 vols. Brünn, 1835-40), Koristka (Vien. 1861), and Dudík (5 vols. Brünn, 1860-71).

Moravians, properly **Moravian Brethren**. The name of 'Brethren of the Law of Christ' was assumed by certain followers of John Huss (q. v.), belonging especially to the Taborites (q. v.), who were found in Moravia and Bohemia in the 15th c. In 1467 they formed themselves into a sect under the name of the 'United Brethren,' being known by the name of the Moravian and Bohemian 'Brethren' respectively. In the beginning of the 16th c. they numbered 200,000, but in 1627 they were driven from both countries and took refuge in Poland, Saxony, and Prussia. The modern sect of M. B. was founded by Count Zinzendorf, a Saxon nobleman, who had been educated chiefly among the Pietists of Halle, and had the desire to realise the idea of his godfather Shener and found a church within the Church. With this object he founded a colony on his estate of Berthelsdorf in Upper Lusatia, June 1722, and appointed a zealous young Pietist, J. A. Rothe, as pastor of the parish. The nucleus of the settlement was Christian David, one of the old Hussite Moravians, and two brothers, Augustin and Jakob Neisser, with their families, who built the first houses of a village which received the name of Herrnhut ('Watch of the Lord'), and increased so fast that in ten years after it contained 600 inhabitants. At first the settlement was simply a community of Lutheran Pietists, but about 1727 disputes arose among them as to Election and the Lord's Supper, while some of them began to forsake the parish church and hold separate services in a hall in the village. A reconciliation having taken place, the name of the old M. B.—'United Brethren'—was adopted, as well as their plan of forming an organised ministry, namely of choosing 'elders' by lot. A few years after (1734) David Nitschmann was chosen by lot and consecrated a bishop by D. E. Jablonsky, Chaplain to the King of Prussia, and Senior Bishop of the dispersed Brethren.

In 1736 Zinzendorf was banished from Saxony for 'teaching false doctrine and disseminating dangerous principles,' and he spent the rest of his life in establishing throughout Europe settlements similar to the original one, and organising the mission work of his sect. At the end of 1873, the whole number of M. in Germany was 69,139; in Great Britain 5548; in the rest of Europe, 7771; in N. America, 11,375; and their total number, including all missions, was 95,924. Their chief settlements in England are Fulneck near Leeds, Fairfield near Manchester, and Ockbrook near Derby. Their theological position is that of the Evangelical Lutherans, or very nearly that of the Evangelicals in the Church of England. See Hagenbach's *German Rationalism* (Clark, Edinb. 1865), and the *Moravian Manual*, published at Bethlehem, U.S.

Moray (Celtic, 'the land on the sea-coast'), the former name of a county in the N. of Scotland, now called Elginshire (q. v.) from its capital.

Moray Firth, an inlet of the North Sea, in the N.E. of Scotland, extending for about 60 miles between the counties Ross and Cromarty, on the N.W., and Inverness and Elgin on the S.E. Its extreme width from Tarbetness to Burghhead is 15 miles, and its depth 20 fathoms. It is continued S. by Inverness Firth, and W. from Inverness by Loch Beauly, which receives the River Beauly. Its N. shore is indented by the narrow Cromarty Firth, 20 miles long. Inverness Firth is the N. terminus of the Caledonian Canal. The name M. F. is sometimes applied to the greater inlet stretching from Wick to Fraserburgh, and including M. F. proper and Dornoch Firth. M. F. has good herring and haddock fisheries.

Morbid Appetite may consist of an excessive and irresistible desire for food which is natural and healthy, for unusual articles of diet, or for such articles as are positively injurious or revolting. Excessive appetite is occasionally characteristic of certain forms of disease, and it may be developed after recovery from acute and exhausting diseases. Chloretic and hysterical women have frequently an inordinate desire for such articles as chalk and lime, and abnormal appetite is common to women in the earlier stages of pregnancy. Unnatural appetite, or the desire to devour articles which are not food, and which are utterly revolting, is sometimes to be met with in pregnancy, and is common among the insane.

Morbihan (Celt. 'little sea'), a maritime department of France, is bounded N. by Côtes-du-Nord, E. by Ille-et-Vilaine, S.E. by Loire-Inférieure, S.W. by the Bay of Biscay, and W. by Finistère. Area, 2623 sq. miles; pop. (1872) 490,352. The coast-line, broken by five bays and by the promontory of Quiberon, is fringed by numerous islands, of which Belleisle (q. v.) is the largest. Heath-clad offshoots of the Montagnes-Noires, rising in the N. to 590 feet, and sloping gradually southwards into vast fertile plains, give rise to the Oust, Blavet, and other streams. The climate is moist and temperate, and the soil, though badly cultivated, yields abundance of corn, flax, hemp, and fruits, 905 sq. miles being under crops, and 1058 heath and pasture, while 9,700,000 gallons of cider are made annually. Cattle-rearing, pilchard fisheries, the manufacture of cloth and linen, and iron-mining, are the chief industries. Two branch lines of railway and one canal traverse the department, the principal towns of which are Vannes and L'Orient.

Mordants. See DYEING.

Mordaunt, Charles, Earl of Peterborough, son of Lord Mordaunt, was born in 1658, served in the navy under Admirals Torrington and Narborough, and forsook it for the army, in which, at the siege of Tangiers, he gained some credit. After the Revolution of 1688, in which he was an ardent supporter of the Prince of Orange, M. gained a place in the Treasury, and was made Earl of Monmouth. In 1697 he succeeded to the earldom of Peterborough. It was not till 1705 that he found his true sphere of action, when he was nominated Commander-in-Chief of the English and Dutch soldiers sent to assist the Arch-Duke Karl of Austria, who was struggling for the Spanish crown. He occupied Valencia without striking a blow, and would have marched to Madrid had he been allowed. After besieging Barcelona for three weeks, he captured the fortress of Monjuich, and, with a small band of men, forced the town to capitulate. He set the Catalans against the Castilians, and chased Count Las Torres into the mountains, returning in triumph to Valencia (February 1706). With 3000 men he harassed a Spanish army which had gone to the rescue of Barcelona, and compelled a French fleet which had appeared before the town to withdraw. Once more M. wished to make a rapid march on Madrid. His counsels being for a second time rejected he retired to Genoa, but the good-fortune of the Austrians then forsook them. In January 1707 he again joined them as a simple volunteer, but was recalled to England, received a Parliamentary recognition of his services (January 1711), performed diplomatic services in Italy, Austria, and Sicily, became governor of Minorca, and, under George I., was appointed Commander-in-Chief of the naval forces. He died at Lisbon, 25th October 1735. M. was on intimate terms with Swift, Pope, and Berkeley, and wrote some indifferent trifles in prose and verse. He was a rash, showy, courageous man, surprisingly fertile in ingenious expedients that perplexed his slower-witted adversaries, and altogether one of the most unique and interesting charac-

ters of his age. See Lord Mahon's *War of Succession in Spain*; Macaulay's *History of England*, and Eliot Warburton's *Memoir of C. M., Earl of Peterborough and Monmouth, with Selections from his Correspondence* (Lond. 2 vols. 1853).

More, Hannah, an English authoress, was born at Stapleton, 2d February 1745, and kept a school at Bristol for some time. Her first work was a pastoral drama entitled *The Search after Happiness* (1773). Her literary life was long and successful. She died at Clifton, 7th September 1833. Of her many works these are the best:—*Sacred Dramas* (1782), *An Estimate of the Religion of the Fashionable World* (1791), *Strictures on the Modern System of Female Education* (1799), *Celebs in Search of a Wife* (1809), *Practical Piety* (1811). H. M. was an excellent, pious, and sensible lady; but she always wrote books with a moral, and occasionally the moral is the best of them. Her poetry is still less read now than her prose. A complete edition of her works in 11 vols. appeared in 1853. See Roberts' *Memoirs of the Life and Correspondence of Mrs. H. M.* (Lond. 4 vols. 1834). Her *Letters to Zachary Macaulay* were published in 1860.

More, Henry, born at Grantham, Lincolnshire, October 12, 1614, was educated at Eton, afterwards studying at Christ's College, Cambridge, where he obtained a fellowship. Early abandoning the Calvinism in which he had been reared, he gave himself up to mysticism, studying in particular the writings of the Neoplatonists. In 1642 he published *Psychodia Platonica, or a Platonical Song of the Soul*, containing much subtle thought clothed in poetry never better than Bunyan's. He likewise published *The Threefold Cabbala*, an explanation of the first chapters of Genesis, *The Mystery of Godliness*, *The Mystery of Iniquity*, *A Discourse on the Immortality of the Soul*, *Medela Mundi, or Cure of the World*, and other books of less importance. He was the last of those in England who embraced the Renaissance Platonism of Italy. His philosophy attempted to make matter contingent, metaphysics being with him the science of incorporeal existence. His ethics, like those of all Platonists, were high toned; practically, he was benevolent to a fault, and although displaying an amusing amount of naïve egotism, his writings imbue the reader with sincere admiration and respect for their author. He translated his works into Latin in 1679. Refusing tempting offers of church and university preferment, he lived the life of a recluse, and died 1st September 1687. See his *Life*, by Ward, (Lond. 4th ed. 1712), and Vaughan's *Hours with the Mystics* (Lond. 1856).

More, Sir Thomas, only son of Sir John M., a judge of King's Bench, was born in Milk Street, London, 1478. He was sent to St. Anthony's School, in Threadneedle Street, and thence passed as a page into the household of Cardinal Morton, a generous patron, who discovered his rare gifts, predicted his future fame, and sent him to Oxford in 1497. He entered Canterbury, now included in Christ's College, learned Greek of Grocyn and Linacre, made lifelong friends of Erasmus, Latimer, and others, and proceeded to London with the reputation of great scholarship and refinement. At Lincoln's Inn he studied law; and during this period of his youth he seems to have become somewhat fanatical in his religious observances, wearing hair shirts, scourging himself on Fridays, and subjecting himself to other penances of the utmost severity. He recovered, however, at sight of a Miss Colt, in Essex, whom he married, soon after entering Parliament and being called to the bar. M. was rapidly attaining distinction as a lawyer and a politician when his effective opposition to the marriage-grant of the Princess Margaret lost him the favour of Henry VII., and almost brought about his expulsion from the country. But the son's smile succeeded the father's frown; Henry VIII. pressed him with favours. In 1514-15 he was employed in two embassies to the Netherlands; in 1516 he became a Privy Councillor; in 1521 Knight and Treasurer of Exchequer; in 1523 Speaker of the House of Commons; in 1526 Chancellor of the duchy of Lancaster; and in 1529 successor to the disgraced Wolsey as Lord Chancellor. By this time he had written the *History of the Life and Death of King Edward V., and of the Usurpation of Richard III.*, probably founded on Morton's data (1509, printed in 1557), and *Utopia*, published in Latin, first at Louvain (1516), next at Basel (1518), and in the English translation of Robinson in 1551. In this *Utopia* (the name is Greek for 'nowhere'; in his letters he sometimes Latinises it, as *Nusquam*), M. discourses of an ideal state with ideal

laws. The book is a loosely-built romance, after the pattern of Plato's *Republic*, wherein much is plainly fantastic and chimerical, and much plausible and sensible: under all its extravagances there runs a current of earnestly suggestive, philosophic, catholic thought, strangely contrasting with the politics of the day, and even with M.'s own conduct in one particular. The last chapter, 'on the religion of the Utopians,' is the first word in behalf of the great doctrine of Toleration to be found in the English or any other tongue; but his bitter hostility to the Reformers—Tyndale especially—productive of *The Dialogue* (1529), *The Supplication of Souls* (1529), &c., is not in keeping with the wise and gentle liberality of his immortal book, and is the only shadow on his lofty character. It may be noticed by way of extenuation, that the *Utopia* was published before the Reformation had begun, and when good men still thought of purifying the Church without the violent remedy of secession. To M. the policy of Luther and his coadjutors seemed revolutionary and anarchic. Even in the passage where the religion of the Utopians is discussed, he uses language which shows his aversion to violent and unbridled speech; and there was much in the demeanour and speech of the early Protestants to lead M. to suppose that he was suppressing treason rather than strangling liberty. It is marvellous to note how many things M. says are practised only in Utopia, which have since been extended to Great Britain and other civilised countries. Admirers of the Ballot Act, e.g., may find it in Bk. ii. chap. 3. Altogether one is struck with the prescient or prophetic character of M.'s politics. In 1532 the reason of M.'s appointment as chancellor became apparent. Henry desired him to give his approval of Catherine's divorce. M. delayed answer, but foreseeing only trouble in his office, resigned the seals, returning to the secure joys of home and family with the childlike simplicity and unaffected lowliness which made his nature so lovable. His first wife had died, and for the benefit of his three daughters and his son he had married a shrewish widow—*nec bella nec puella*, he writes himself. Nevertheless Erasmus and others speak with admiration of the happiness, virtue, and piety which the example of the master caused to reign in the household. In 1534 an Act was passed securing the crown to the issue of Anne Boleyn. M.'s assent to this was asked; he refused it, and was lodged in the Tower, where he lay for a year. He was tried in 1535, and on the 6th of July was beheaded, his wanted just being ready even for the executioner, 'You will never get credit by beheading me, my neck is so short.' Amid an age of notables M. stands forth as the man of staunchest principle, purest morals, sincerest piety—a perfect English statesman and scholar. His last male descendant was a Thomas M., who died in 1795, while his family finally became extinct in 1815 by the death of Lady Ellenborough. M.'s collected works, Latin and English, were published at Louvain in 1556–57. The best translation of *Utopia* is Bishop Burnet's; there is an exact reprint of Robinson's by Arber. See *The Life of Sir Thomas M.*, by his son-in-law, William Roper, first printed in 1716, and that by Sir J. Mackintosh (Lond. 1830).

Morea, the modern name of the ancient Peloponnesus (q. v.), the physical features of which have been already described under GREECE. Area 8288 sq. miles; pop. (1870) 645,389. The etymology of the name M. has been much disputed, those who, like Fallmerayer, hold the Slavonic origin of the Modern Greeks deriving it from the Slav. *more*, 'sea'; Salverte referring it to a transposition of the letters of *Romea*; and the popular notion explaining it by the resemblance of the outline of the peninsula to the leaf of the mulberry (Gr. *moron*).

Moreau, Jean Victor, a famous French general, was born at Morlaix, in Brittany, 11th August 1763, educated for the law at Rennes, forsook his studies to join the army; returned to jurisprudence once more, but on 10th September 1791, owing to his democratic leanings, was appointed chief of the 1st battalion of Ille-et-Vilaine, with which he joined the army of the N. under Dumouriez. By the 25th Germinal 1794, M. had been appointed general of division, through the influence of Pichegru, who gave him a corps with which he operated successfully in Flanders. It was during his triumphs in this campaign that his father was brought to the scaffold at Paris, owing to a suspicion of his plotting with the detested *émigrés*. In 1795 M. succeeded Pichegru as the head of the army of the N., and in 1796 superseded him in the

command of the army on the Rhine and Moselle. During the same year he defeated the Austrians under General Wurmser, checked the Archduke Karl, and being menaced by a force vastly more numerous than his own, retired fighting towards the Rhine, and effected one of the most masterly retreats on record. After a temporary retirement, produced by a misunderstanding with the Directory, and having achieved some fine victories in Italy, M. once more commanded the army of the Rhine (1800), routed the Austrians over and over again, gained the battle of Höchstadt, and signed the armistice of Presdorf. On the 3d of December 1800, he won the victory of Hohenlinden over the Archduke Johann, and was marching towards Vienna when the armistice of Steyer stayed him. His military glory became at this point too great for the forbearance of Napoleon, who had little difficulty, by means of spies, in finding him guilty of treasonable speeches. And it is certain that M., off the field, was easily influenced from the outside to criticise severely the government of the First Consul. Not only so, but it has been proved that he participated to a certain extent in the royalist plots of Cadoudal and Pichegru. The result was that he was arrested, and condemned to imprisonment (10th June 1804), which was commuted to a period of exile. For years he lived in America, returned to join the allies in 1813, and was shot with a cannon-ball (August 27th) at Raecknitz, his death-bed being surrounded by the emperors of Austria and Russia, and the king of Prussia. He died, 2d September, at Laun in Bohemia, and though he conscientiously arrayed himself against Napoleon, his country remembers him with pride as the second greatest of the revolutionary generals. See Thiers' *Histoire de la Révolution* and *Histoire du Consulat et de l'Empire*; and Beauchamps' *Vie politique, militaire, et privée du Général M.* (Par. 1814).

Morecambe Bay (Celtic, 'the bend of the sea'), on the N.W. coast of England, separates the main part of Lancashire from the outlying portion of Furness. It receives the Kent, Keer, and Lune, and is very shallow, a vast expanse of sand being exposed at low tide. It is 12 miles broad from Piel to Fleetwood, and extends inland for 15 miles.

Moreen, a stout, worsted cloth watered like Moire (q. v.), whence its name. It is much used for curtains.

Morel is the popular name of *Morchella*, a genus of *Fungi* belonging to the family *Ascomycetes*, division *Discomycetes*, of De Barry's arrangement, and to the order *Elvellacei* of English authors. The common M. (*M. esculenta*) is a well-known edible fungus sold in the shops. It may be cooked in a variety of ways when fresh, forming a very palatable dish, or may be dried and kept in reserve for flavouring purposes. In growth it attains a height of 3 or 4 inches, half consisting of a smooth white cylindrical hollow stem, surmounted by a pileus or cap of variable conical to cylindrical shape, attached by its base to the stem, and having its surface covered with deep pits. In parts of Europe and Asia it is plentiful, forming a profitable article of collection for the German peasantry; in Britain it is rather uncommon. The place of growth is usually woods, showing a marked preference for ground where fires have been made, as in charcoal burning. The half-free M. (*M. semilibera*) is also an esculent species, found under hedges in different parts of Britain. In it the conical pileus is not fully attached to the stem as in the common M.

Morelia, capital of the State of Michoacan, Mexico, delightfully situated among the mountains, 6350 feet above the sea, and 130 miles N.W. of Mexico, was founded by the Spaniards in 1541, and called Valladolid till 1828, when it was renamed from the revolutionary chief Morelos, who as well as Iturbide was born here. It is the seat of an archbishop (since 1863), and has a beautiful cathedral (built 1745), a college, a splendid arched aqueduct for the supply of water, and a large cotton factory (since 1868), with 2500 spindles and 78 looms. Pop. 30,000.

Moreton Bay, an indentation on the coast of Queensland, 65 miles long and 20 broad. It is shut in by Moreton and Stradbroke Islands, and affords safe anchorage to vessels of any size and number. Five rivers—the Arrowsmith, Logan, Brisbane, Pine, and Caboolture—fall into M. B., and are navigable by vessels of moderate size. M. B. is the gate of a vast district of great fertility.

Moreton Bay Chestnut, in Botany, the tree *Castanospermum Australe*, belonging to the natural order *Leguminosæ*. It is a native of Queensland, and is a handsome tree of rapid growth, attaining an average height of 85 feet, and producing beautiful red and yellow flowers. The pods contain edible seeds resembling the chestnut, whence its popular name. The wood is of small value.

Moreton Bay Pine, in Botany, the tree *Araucaria Cunninghamii* (natural order *Conifera*). It is indigenous to Queensland, where it is very abundant, and is much valued on account of its beautiful and serviceable timber. It attains a height of from 150 to 200 feet, and grows in the form of a pyramid. A clear white resin exudes from the trunk and hangs down in crystals resembling icicles, the masses thus formed being sometimes 3 feet long, and from 6 to 12 inches broad.

Morgan, Lady (*née* Sidney Owenson), the daughter of an actor, was born at Dublin about 1786, published a volume of poems when fourteen, and put forth three novels, *St. Clair* (1804), *The Novice of St. Dominick* (1805), *The Wild Irish Girl* (1806). She married Sir Thomas Charles Morgan in 1812. Besides a small host of dashing, humorous, interesting, withal silly novels, she wrote *France* (1817-18), *Italy* (1821), *Life and Times of Salvator Rosa* (1823), *Woman and Her Master* (1840), &c. Lady M. died in London, 13th April 1859. Her works were collected in 1855. See her *Autobiography, Diary, and Correspondence* (1862; 2d ed. 1863); and W. J. Fitzpatrick's *Lady M.*, &c. (1860).

Morganatic Marriages (*Matrimonium ad morganaticum*, or *ad legem salicam*, German, *Morganatische Ehe*). Members of the royal families of Germany can only intermarry with those of 'Ebenbürtigkeit,' or equal birth-rank. A prince may, however, contract a left-handed or morganatic marriage with a woman of inferior status, which does not raise her to his own rank, while it gives legitimacy, though not right of succession, to his children. Such marriages are common enough not only among the princely but the noble houses of Germany. One of the most celebrated was that of King Friedrich Wilhelm III. of Prussia with the Countess Augusta von Harrach, whom he created Princess of Liegnitz. Princes of the blood royal of Great Britain, if under twenty-five years of age, must obtain the approval of the sovereign to their marriages, or if over twenty-five, the consent of Parliament, otherwise the connection is of a morganatic nature. The term seems to be derived from the old Gothic word *morgjan*, 'limited,' not as some imagine from *morgengabe*, 'morning-gift' or 'dowry,' the only privilege obtained by the wife.

Morgarten, a mountain pass in the Swiss canton of Zug, between the M. Hills and Lake Egerie. Eight years after the expulsion of the Austrian governors, Leopold returned at the head of a splendid army to subdue the forest cantons, and was here defeated (15th November 1315) by the Swiss, who had hardly one-twelfth of his numbers.

Mor'ghen, Raffaello Sanzio, was born at Florence, June 19, 1758. He came out as an artist in the Roman school of Volpato, and in 1793 was engaged by the Grand Duke of Tuscany to teach engraving at Florence. Among his earliest prints were the 'Madonna della Seggiola,' and Raffaele's 'Transfiguration,' a copy of which now fetches more than £20. Perhaps his most famous work was the engraving of Da Vinci's 'Last Supper,' an undertaking in which he succeeded especially because in that picture the rendering of aerial effect—in which he always failed—was not severely taxed. He died April 8, 1833. In all he engraved 73 portraits, 47 religious and 44 historical and mythological pieces, 24 views and landscapes, and 13 vignettes, &c. His pupil Palmerini published a catalogue of his works with a biographical memoir in 1824.

Morgue, La, a public building in Paris, on the *Quai de Marché Neuf*, where the bodies of persons found dead are exposed for identification. The bodies lie thus for three days, and the number placed in the M. is about 300 annually. The word *M.* originally meant merely the outer court or vestibule of a prison. The name is now commonly applied to dead-houses in other cities.

Morion (Fr.; from Ital. *morione*, Span. *morro*, 'round'), a headpiece of iron or steel, of Spanish origin, and commonly worn by German, French, and Italian foot-soldiers in the 16th c. It was surmounted by a high crest, and the rim, being turned up and pointed at the front and back, had a crescent form at the side, as shown in the cut.

Morion.

Morison, Robert, a Scotch botanist, was born in Aberdeen in 1620, and studied at the university of his native town. During the civil war he fought in the Royal army, and was wounded at the Bridge of Dee. He afterwards went to France, and took the degree of M.D. at Angers, and was appointed botanist to the Duc d'Orleans at Blois. He became botanist to Charles II. in 1660, with the charge of the Botanic Garden at Oxford. He died in London, November 10, 1683. He taught a new classification of plants in his chief work, *Plantarum Historia Universalis Oxoniensis* (2 vols. published 1676-99).

Moriso'nians. See EVANGELICAL UNION.

Morland, George, an English painter, born in London 26th June 1763, sold his drawings at the age of six, and at sixteen was a finished artist and a sad blackguard—thanks to the education of a greedy father. He painted with great freedom and inimitable humour. His subjects were usually animals, occasionally rural landscapes and interiors. The two he especially affected were a litter of pigs and a pothouse parlour. He died a palsied drunkard in a sponging-house in Eyre Street, 29th October 1804.

Moritz, Duke, and afterwards **Elector of Saxony**, eldest son of Duke Heinrich the Pious of Saxony, born 21st March 1521 at Freiberg, joined the Protestant party in 1539, married (1541) Agnes, daughter of Philipp, Landgraf of Hessen, and the same year succeeded his father in the government of the ducal part of Saxony. He at first supported the Schmalkaldic League against Duke Heinrich of Brunswick, but when it came (1546) to an open rupture with the Emperor he sided with the latter, who in a secret treaty promised him the lands and title of his cousin, the Elector Johann Friedrich. These he obtained after the overthrow and capture of the Elector at Mühlberg in 1547. But as Karl V. persisted in keeping his father-in-law a prisoner, and appeared to be striving to make the imperial power a political and ecclesiastical absolutism in Germany, M. besieged Magdeburg as a pretext to collect an army, and forming a secret league (1551) with Henri II. of France, suddenly fell upon Karl, and extorted from him the Peace of Passau (31st July 1552). The next year M. attacked the Markgraf Albrecht of Brandenburg, who would not recognise the Passau treaty, and gained a decisive victory at Sievershausen (9th July 1553), but died two days after of a wound. M. was an able ruler, but of an ambition that left little choice to his conscience of the means to increase his power. He was a reformer in home affairs, employing the confiscated estates of monasteries to found the three 'Fürstenschulen,' and to better endow the University of Leipsic. He left only a daughter, Anna, who (1561) married Prince William I. of Orange. See Langenn, *M. Herzog und Kurfürst von Sachsen* (2 vols. Leips. 1841).

Moritz, Graf von Sachsen, better known as Marshal Saxe, born at Goslar, 28th October 1696, was the illegitimate son of King August II., Elector of Saxony, and Marie Aurora, Gräfin von Königsmark. He began his career (1709) in Flanders under Eugene and Marlborough, entered the French service in 1720, and in 1726 was made Duke of Courland. In the war of the Polish Succession, M. decided the victory in the battle of Ettlingen (1734), took Philippsburg, Prag, and Eger (1741), and seized the lines at Lauterburg. Being appointed Marechal of France in 1744, he conducted the campaign in Flanders, gained the victory of Fontenoy (11th May 1745), was again victorious at Raucoux, and took Bergen-op-Zoom (1747), and Maas-tricht (1748). After the Peace of Aachen (1748) he lived at his castle of Chambord till his death, 30th November 1750. In 1776 Louis XV. erected over his grave, in the Protestant church

of St. Thomas at Strassburg, a magnificent monument by Pigalle. From an illegitimate son of M. was descended the Marquise Dudevant ('George Sand'). His *Reveries Militaires* (best ed. 1757) contain many original views on the art of war. See M.'s *Lettres et Mémoires* (1794), and the biographies by Taillandier (1865), Weltzien (1867), and Weber (2d ed. 1870).

Moritz, Prince of Orange, and Graf von Nassau, son of Prince William I. of Orange, was born 14th November 1567 at Dillenburg, and, after his father's murder in 1584, was chosen Commander-in-Chief and Stadtholder of the Provinces of the Netherlands. He resembled his father in prudence, persistency, and military skill, wrested from the Spaniards forty towns and gained three victories before the truce of 1609 stopped hostilities. M. strove to make himself an absolute ruler by taking advantage of the disputes between the Arminians and the Gomarists, the latter of whom he zealously supported; but was at length forced to abandon his ambitious plans. He died at the Hague, unmarried, 23d April 1625.

Morlaix (Celt. 'the place on the sea-shore'), or **Mont-roules** (Med. Lat. *Mons Relaxus*), a river-port of France, in the department of Finistère, stands at the confluence of the Jarlot and Kefflent, 5½ miles from the sea, and 35 miles E.N.E. of Brest by rail. The two hills on which the town is built are linked by a splendid railway viaduct 210 feet high; and the chief buildings are the churches of St. Mathieu, St. Melaine, and St. Martin-des-Champs. The Château du Taureau, commanding the harbour, which intersects the town, is bordered by fine quays and promenades. M. is mainly frequented by coasters, and has manufactures of cloth, oil, and tobacco, and a trade in lead, linen, corn, &c. Pop. (1872) 11,536.

Morley, Henry, born in London, 1822, educated at Newniew and King's College, London, and practised as surgeon at Madeley in Shropshire (1844-48); was a schoolmaster for two years at Liscard, Liverpool, and in 1851 settled in London as a journalist, writing for *Household Words* and the *Examiner*. Of the latter he became editor. In 1865 he was appointed Professor of English Language and Literature at University College, and in 1870 was appointed Examiner in English Language, Literature, and History to the University of London. M. has a richly cultivated mind, fine sympathies, a clear perception of literary beauty, and a vigorous critical faculty. Among his numerous writings may be noted *How to Make Home Unhealthy* (1850); *A Defence of Ignorance* (1851); *Life of Palissy the Potter* (1852); *Life of Jerome Cardan* (1854); *Life of Cornelius Agrippa* (1856); *Memoirs of Bartholomew Fair* (1859; new ed. 1874); *Fairy Tales* (1859-60; new ed. 1877); *Journal of a London Playgoer* (1866); *Tables of English Literature* (1870); *Clement Marot and other Essays* (2 vols. 1871); his useful *First Sketch of English Literature*, in its 3d edition; the skeleton of a larger work in progress entitled, *English Writers*, the first three parts of which have been already published, embracing *The Celts and the Anglo-Saxons*; *From the Conquest to Chaucer*; and *From Chaucer to Dunbar*. His latest work is *Illustrations of English Religion* (1877).

Morley, John, born at Blackburn, Lancashire, in 1838, was educated at Cheltenham, and entered Lincoln College, Oxford, where he took the degree of B.A. in 1859. He succeeded Lewes as editor of the *Fortnightly Review* in 1867. He has written *Edmund Burke, a Historical Study* (1867); *Critical Miscellanies* (1871); *Voltaire* (1871); *Rousseau* (1873); *On Compromise* (1874); *Critical Miscellanies* (2d series, 1877). For some time past M. has been making a strong impression on that section of society which thinks. He has a brilliant, lucid, and powerful intellect; he grasps the characteristics of an age or an individual with vivid insight, and describes them with a keenness, precision, and pungency that have the charm of rhetoric without its taint. Rationalistic, yet sympathetic, he resembles his departed master, John Stuart Mill, in the vigour of his logic, the catholicity of his culture, and his almost poetic enthusiasm for the progress of the race. Mark Pattison (*Academy*, October 13, 1877) says that in the course of the last few years M. has 'risen out of the class of brilliant periodical essayists into the higher class of the very few who influence opinion.'

Mormons is the name given to a sect calling themselves 'The Church of Jesus Christ of Latter-Day Saints,' which was

founded in 1830 by Joseph Smith, and whose head-quarters is at Utah, United States. Joseph Smith (born 23d December 1805, at Sharon, Vermont, U. S.), at fourteen began to have 'visions' of God the Father, and the Son, who told him that the religious sects then existing were all in error. In 1823 he had another vision, in which a glorious personage told him that the time had now come for the Gospel to be fully preached, and gave him directions where he should find, buried in the earth, some gold plates inscribed with the writings of the ancient prophets. He found the plates in the place indicated, although they were not fully entrusted to his keeping till three years after (1827). According to his description they were of fine gold, 8 inches by 7, and bound together by three rings, 'passing through the whole at one edge, into a volume 6 inches thick. Along with the plates, besides a breastplate and a sword, he found a pair of spectacles, with two three-cornered diamonds fixed in the glasses. This was the Urim and Thummim, by means of which the small characters inscribed on the plates could be interpreted. These, according to the authority of the book itself, were in the 'Reformed Egyptian' language. Only eleven persons besides Smith were ever privileged to see the plates, which, with all the other articles, were returned to the angel, and never seen more. In 1827 Smith told his story to a farmer in Palmyra, New York, named Harris, who agreed to support him while translating his plates. The translation was dictated to Harris, and afterwards to a schoolmaster, Oliver Cowdery, by Smith, who sat behind a curtain, and was finished in 1829. While engaged in this work, Smith and Cowdery had a vision. John the Baptist appeared to them, and in the name of Jesus Christ consecrated them priests of the order of Aaron, and commanded them to baptize each other. When they had done this 'the Holy Ghost fell on them, and the spirit of prophecy was granted them.'

In 1830 the Church of Christ was started at La Fayette, New York, with six members, who, when they had ordained each other, received the gift of prophecy from the Holy Ghost. Several spectators were converted and baptized, and at the first Conference (June 1830) thirty members were present. Missionaries were now sent through the States, and gained many converts, of whom the most notable were Brigham Young, two brothers Pratt, and Rigdon. This success, however, excited hostility on the part of unbelievers. Judicial proceedings were taken against Smith for fraud and imposition, and when he was acquitted, he and his friends were threatened with violence. To avoid this they removed in 1831 to Kirtland, Ohio, and not long after a party of about 1200 settled in Jackson County, Missouri, calling the place 'Zion, the New Jerusalem, where Christ would shortly reign in person.' But trouble was again brewing for the Saints in both settlements. It began to be rumoured that they practised communism in their goods and wives. Their newspapers published abolitionist views, and declared that all unbelievers would soon be rooted out of the State. In this way popular indignation was greatly excited against them. In March 1832 Smith and Rigdon had been tarred and feathered by a mob. Those in Missouri were so harassed that they abandoned their homes in the middle of winter (1833-34) and removed to Liberty, Clay County. It was at this time that the presidency of three (Smith being first, and Rigdon second), and the high court of twelve apostles were established as the ruling authorities of the Church, and the formal title of 'the Church of Jesus Christ of Latter-Day Saints' was adopted (May 1834). From this time the M. remained unmolested for nearly four years. In the autumn of 1837, however, the business which Smith carried on in Kirtland failed, and the bank which formed part of it stopped payment. Smith and Rigdon were indicted for swindling, and to avoid being arrested fled to Missouri. Here, owing to internal dissensions, Harris, Cowdery, Rigdon, and some others of the first M. were expelled from the Church, although Rigdon was soon readmitted. And now prosecution from without began anew. But by this time the M. were strong enough to retaliate, and regular warfare ensued. The State militia was called out to keep the peace, and the M. were driven, with much suffering and some loss of life, across the Mississippi into Illinois (1838), whither they were followed by the President and other leading men who had been arrested and sentenced to be shot, and then allowed to escape. Here a new settlement was formed called Nauvoo [Heb. (*sic*) 'beautiful'], at which they soon numbered 15,000. In 1840 a charter of incorporation was obtained. The corporation assumed an independent jurisdiction, and a militia

consisting of all able-bodied men was organised. In 1844 Smith, who was now absolute ruler, both in temporal and spiritual matters, over 20,000 persons, offered himself as a candidate for the presidency of the United States; but this only roused more hostility against him. For some time, too, he had been cautiously teaching polygamy under the guise of a theory regarding 'spiritual wives'; indeed he had had a revelation on the subject in 1843, although it was not published till afterwards. But now the unbelievers started a newspaper in Nauvoo itself, the first number of which contained the affidavits of sixteen women that Smith or other prominent M. had attempted to seduce them. The M. destroyed the office of the paper, and resisted the warrants procured against them therefor; and the whole neighbourhood rose in arms against them. To avoid a general massacre, Smith and some others surrendered themselves to the governor of the State, who had promised them safety and a fair trial, and were lodged in prison at Carthage. But a rumour having got abroad that the governor wished their escape, 200 men disguised as Indians broke into the prison (June 27, 1844), and shot Smith and his brother dead, wounding the rest.

On the death of Smith, Brigham Young was elected President by the twelve apostles. But persecution by the unbelievers still continued, and an exploring party, headed by the President, set out (Feb. 1846) to seek a new home in the far West. In September the city of Nauvoo was burned by an armed mob after several days' siege, and the remnant of the M. driven across the Mississippi into Iowa, where the exploring party had halted. They now left Iowa for the valley of the Great Salt Lake, enduring incredible hardships on the march and during the succeeding winter (1848-49). The new city which quickly sprang up received the name of Deseret (Ref. Egyptian! 'honey-bee'). In 1850 the district was admitted into the United States as a territory, under the name of Utah, and Brigham Young was named the first governor. Differences soon arose with the officers appointed by the President of the States, and in 1854 and 1856 they had all to flee to Washington. In 1857 troops were sent to enforce obedience, with whom the M. had several skirmishes. In 1860 the troops were withdrawn, but in 1862 a permanent camp was formed near the city to overawe the M. In 1871 some of the leading M. were indicted for bigamy. In the first case tried the defendant was convicted; but on an appeal the proceedings were quashed, which the M. ascribed to a special interposition of Providence. Brigham Young has just died (1877), and the twelve apostles have had a revelation (Sept. 4th) instructing them to preside over the Church without a new President.

The exact numbers of the M. it is impossible to estimate. The population of Utah in 1872, when the fourth unsuccessful attempt was made to obtain admission as a State of the Union, was 105,000, although, of course, a certain proportion of these were Gentiles. But there are few countries in the world where the M. have not tried to gain converts. A large proportion of those they have gained, however, have come from Britain and Denmark, because in every other country the missionaries have been prevented preaching, or have been expelled. 'Of late years,' it has been asserted by a good authority, 'the immigration into Utah from the European missions has varied from 1000 to 4000 annually.'

The principal sacred books of the M., besides the Bible, are three: First, the *Book of Mormon*, translated by Smith from the gold plates, published in 1830, and styled *An Account written by the hand of Mormon upon Plates taken from the Plates of Nephi. Translated by Joseph Smith*. It contains what professes to be a history of the American Continent, from its first colonisation after the dispersion from Babel, down to the year A.D. 420, when Moroni, the last of the Nephite prophets, buried his plates in the hill of Cumorah. The account given of the book by unbelievers is that it was written about 1809 by a preacher of an obscure sect named Spalding, who had been led by the discovery of some remains of an extinct race to write a romance connecting the race both with the Israelites and the American Indians, and that Smith obtained by some means a copy of Spalding's M.S., which had never been published, and made such alterations on it as suited him. Another sacred book, which is the chief authority on doctrine, is *The Book of Doctrine and Covenants of the Church of Jesus Christ of Latter-Day Saints, selected from the Revelations of God, by Joseph Smith* (published 1833). The third is *The Pearl of Great Price* (Liverpool, 1851), which is a selection from the revelations, translations, and narrations of Joseph

Smith. Mormon theology is a medley of doctrines and superstitions borrowed from many sources, there being indeed points of resemblance between it and almost every form of religion that ever prevailed in the world—Panthéism, Dualism, Judaism, Christianity—both orthodox and heretical—Mohammedanism, &c. The chief items of the popular creed, as generally preached, are faith in Smith and his successors, repentance, baptism for the remission of sins, reverence for the Bible and the other sacred (Mormon) books, the payment of tithes, absolute obedience to the president and the priesthood. The great peculiarity of the sect is the practice of polygamy, which, however, is a recent innovation condemned by the *Book of Mormon*. It was in 1843 that Smith had a revelation on the subject, but it was not till 1852 that the Sacred Law of Marriage was published or put in practice. M. are popularly known simply as men with a number of wives, and it is on the practice of polygamy that the existence of the sect will greatly depend. At any rate it seems probable that they will soon have to choose between giving it up or leaving Utah. There is a party among the M., including the near relatives of Joseph Smith, who are anti-polygamists, and who affirm that Brigham Young, and not the founder himself, introduced the doctrine and practice of polygamy. But they have not yet ventured to 'split the Church' on the point. Besides the books already mentioned, see a *Compendium of the Faith and Doctrines of the Church of Jesus Christ*, &c. (Liverpool, 1857); *Edinburgh Review*, No. 202; G. A. Smith's *Rise, Progress, and Travels of the Church of Jesus Christ*, &c.; H. Dixon's *New America* (1867).

Mormyridae, a family of Teleostean fishes related to the pikes (*Esoide*). The body is long, the tail slender, and the mouth small. The gill-opening is a mere slit. Its best-known member is the *Mormyrus oxyrinchus*, or sharp-nosed mormyrus of the Nile.

Morny, Charles Auguste Louis Joseph, Comte de, understood to have been the son of Queen Hortense by the Comte de Flahault, was born in Paris, 23d October 1811, educated at the Collège Bourbon, entered the army and served with some distinction in Africa. In 1837 Queen Hortense left him an annuity of 40,000 francs, in 1838 he joined the army, devoted himself to the production of sugar from beet-root, and published a well-informed treatise, *Question des Sucres*. M. was returned to the Assembly (1842), and spoke with capacity on questions of industry. He was one of the chief actors in the *coup d'état* of 1851, and, as Minister of the Interior, counter-signed all the first proclamations and decrees. He was appointed President of the *Corps Législatif* in 1854, and in 1856-57 represented France at St. Petersburg, where he married a rich princess (Trubetskoi). M. was one of the heaviest speculators in stocks and shares. He died at Paris, March 10, 1865. In his *Histoire d'un Crime* (October 1877), Victor Hugo writes of M. as a deadly free-liver, 'possessing all the frivolity consistent with assassination, without conscience, irreproachably elegant, infamous, and amiable; at most a perfect duke. Such was this malefactor.'

Morocco (Fr. *Maroc*, Arab. *Maghrib-el-Aksa*, 'the extreme west'), a sultanate in the N.W. corner of Africa, forming part of the seaboard of the Mediterranean and Atlantic, and extending from the province of Oran, Algeria, in the N.E. to the river Sakiet-el-Hamra in the S.W., a distance of 840 miles in a straight line, and inland from the seaport of Mogadore, on the Atlantic, to the eastern limits of the plateau of Tedmaït, a distance of 860 miles. Area estimated at 268,920 sq. miles; pop. (according to Kohlfs) at 6,000,000, but by others at only 2,750,000. M. is traversed in a direction nearly W.S.W. by the parallel ranges of the higher Atlas Mountains, which culminate some 30 miles S.E. of M. city in Jebel Miltzin, 11,500 feet high, and terminate in Cape Ghir, 60 miles S. of Mogadore, sending off to the S. several lower ranges. An irregular and widespread mountain range is continued from Algeria along the coast to the Strait of Gibraltar, and this wild region, known as the Rif, is occupied by predatory tribes, who owe a merely nominal allegiance to the sultan. In the Rif are the two Spanish ports of Ceuta and Melilla. The sultanate includes the three former kingdoms of Fez, Maghrib, and Taflet, the districts of Sus and Diaa in the extreme S., and an outlying desert portion, comprising Gurara, Tuat, Tidikelt, and the plateau of Tedmaït. The oasis of Tuat is of great importance as a resting-place for

the caravans trading to Murzuk and Timbuktu. From the Atlas Mountains a wide, fertile plain, intersected by various low mountain ranges, stretches towards the Atlantic coast, and here are the chief centres of population. The rivers are invaluable for irrigation, but none of them are navigable. The great plain is watered by the Sebu, Bu-Regreg, Ummer-Rebia, and Tensift. Other rivers of M. are the Muluja, which flows from the Atlas Mountains through the N.E. district of Angad to the Mediterranean, the Draa forming part of the S. boundary, and the Saura and its affluents watering the country to the S.E. of the Atlas Mountains and the district of Tuat, and eventually losing itself in the Sahara. A great part of the interior of M. is entirely unknown to Europeans. The mountains nowhere reach the level of perpetual snow, but the higher peaks of the Atlas are white as late as April, while the lower slopes are clad with luxuriant forests of oak, pine, cedar, and other kinds of valuable timber-trees. In the great western plain the climate is remarkably temperate and equal, the temperature ranging from about 40° to 90° F. The districts along the margin of the Sahara suffer from droughts, and are swept by scorching winds. Agriculture is carried on in a very primitive way; the use of manure, for instance, being almost unknown. Among the products are wheat, maize, rice, sugar, cotton, tobacco, peas and beans, saffron, grapes, oranges, almonds, figs, and dates. The live stock consists mainly of large herds of cattle, horses of a small but spirited breed, and the goats whose skins furnish the famous M. leather. Lions and panthers infest the forests, and other wild animals are the hyena, jackal, and wild boar, and on the skirts of the Sahara, the ostrich and gazelle. Serpents, scorpions, and lizards are common, and the country is frequently visited by the scourge of locusts. Of the inhabitants it is estimated that some three-fourths are Moors, who generally reside in towns, and are frequently men of somewhat superior education. The agriculturists are mostly Berbers, and cattle-rearing is chiefly in the hands of nomad Arabs. The Jews are estimated at 340,000, while the number of Christians is said not to exceed 500. The Berbers and the kindred race of the Shellouls live in the valleys and uplands of the Atlas Mountains, the former towards the E. in the region of Fez, the latter towards the Atlantic. Negroes are held as slaves, and the Bohari, a black tribe, have furnished the *élite* of the Sultan's body-guard for generations. Besides the turbulent inhabitants of the Rif, there are two lawless coast tribes—namely, the Zimous, who live in the forest of Maimora, between Melideyeh and Salee, and the Zvars, who occupy the S. and S.W. of Rabat. The Zvars carry pillage to the very gates of Rabat, and caravans from that place to Dar-el-Baida are constantly driven to the shelter of the many *Kasbs* or strongholds built by Government along the route. Over all M. green tea is esteemed a greater luxury than even coffee, and a prevalent habit is the smoking of kief, the pernicious Indian hemp. The manufactures include M. leather, carpets, shawls (*haiks*), flint-lock guns beautifully inlaid with gold and silver, leather-dyes, coloured tiles, and elegant water-jars. Since the conclusion of a treaty of commerce with Great Britain in 1856 the foreign trade has increased considerably. In 1875 the total exports amounted in value to £1,561,312, and the imports to £1,011,588; the exports to Great Britain to £711,291, and imports from Great Britain to £342,420. The chief port is Tangier, and others are Mogadore, Mazagan, Rabat, Lariche, Dar-el-Baida, and Saffi. There are two capitals, M. and Fez, the principal towns of the interior. M. is divided into twenty-eight provinces, each under a *kaid*, who is military commander as well as absolute governor. The Sultan, a purely despotic ruler, is head of the religion, which is a form of Mohammedanism differing from that of Turkey and Persia by the adoption as a text-book or code of Sidi Beccari's commentary on the Koran. Extortion is universal, and there is not a printing press in the country. Part of the region conquered by the Arabs in the 7th c., M. was included in Barbary till the 15th c. The kingdom of Fez was founded in 787, and that of M. not till 1058. The two states were united in the beginning of the 17th c., and the present dynasty was founded in 1648. The slavery of Christians was prohibited in 1814, and piracy was abolished in 1817. See Augustin's *Morokko* (Pesth, 1845), Renou's *Empire de Maroc* (Par. 1846), Kohl's *Land und Volk in Afrika* (Brem. 1870), and *Main erster Aufenthalt in Marokko* (Brem. 1873), Leared's *M. and the Moors* (Lond. 1876), and C. F. Tyrwhitt Drake's *Literary Remains* (Lond. 1877).

Morocco (Arab. *Marrakesh*), one of the capitals of the sultanate of M., lies in a plain near the N. base of the Atlas Mountains, at a height of 1500 feet above the sea, near the river Tensift, and 130 E. of its port of Mogadore. It is girt by a wall 23 feet high, and 7½ miles in circuit, is supplied with water by aqueducts of ancient construction, and contains some 20 mosques and several large bazaars. The palace of the sultan, outside the walls, is a magnificent building. Great part of the town is in ruins, but there is still considerable industry, especially in the manufacture of red and yellow M. leather. Pop. 50,000, of whom 6000 are Jews. M. was founded in 1072, and became famous as a seat of learning in the 13th c. The Moors of Spain frequently sent their children here to be educated, and during the height of its prosperity the town is said to have had 700,000 inhabitants.

Moron, a town of Spain, province of Seville, 36 miles S.E. of the city of Seville, with which it is connected with rail. It contains the remains of a strong Moorish castle, and is noted for its lime, which is used for many ornamental purposes. Pop. 10,500.

Morpeth, a market-town of Northumberland, England, on the Wansbeck, 17 mile. N.N.W. of Newcastle by the Great Northern Railway. It has a town-hall (1714) designed by Vanbrugh, a parish church of the 14th c., a free grammar-school founded in 1552, and transferred to a new building in 1859, a large gaol, erected at a cost of £80,000, and the Northumberland Pauper Lunatic Asylum (1858-59), which cost £39,000. Some flannel is made, and there are rope-yards, iron and brass foundries, tanneries, breweries, brick and tile works, &c. In the vicinity are stone quarries. The great cattle market formerly held here has been removed to Newcastle. M. sends one member to Parliament. Pop. (1871) of town, 4517; of parliamentary borough, 30,239.

Morpheus (Gr. the 'fashioner' or 'moulder'), in classic mythology was the son of *Hypnos* ('sleep') and the god of dreams. He was so called, because he shapes or forms the dreams of the sleeper.

Morphia or **Morphine** ($C_{17}H_{19}NO_3$), the chief active principle of opium, was discovered by Sertürner 1804. It, and the many other alkaloids present in opium occur in combination with sulphuric or meconic acid ($H_2C_7H_2O_7$). To obtain M. separate, a strong infusion of opium is mixed with calcium chloride, when calcium meconate, with much of the colouring matter, is precipitated, and the hydrochlorates, chiefly of M. and Codeine (q. v.) are left in solution. These are crystallised by evaporation, decolourised with animal charcoal, and redissolved; and from this purified solution M. is precipitated by ammonia. It is further purified by crystallisation from alcohol, being deposited as white rectangular prisms. The chief features of M. are its bitter taste, alkaline reaction, and narcotic poisonous properties. It is sparingly soluble in cold water, and is usually identified by the deep blue colour it gives with neutral ferric salts, and the golden yellow compound it forms with nitric acid.

Medicinal Preparations and Properties of M.—The preparations of M. possess the anodyne and soporific powers of opium; but they act more agreeably, and are less likely to produce headache and nausea, being less exciting and stimulating. *Acetate* of M. is given in doses of from ¼ to ½ a grain, and a solution is used for hypodermic injection. It is also prepared as a liquor, and is given in doses of from 10 to 60 minims. The *Hydrochlorate* and its liquor are administered in the same doses, and also in the form of *Suppository* and as lozenges, and of the latter one or two may be taken occasionally for cough. Each lozenge contains ⅓ grain of *Hydrochlorate* of M.

Morphology, the department of biological science charged with the investigation of the form and structure of living beings. M., as now understood, includes (1) *Anatomy*, or the science investigating the structure of the adult being; (2) *Development*, which traces the history of its evolution from the egg, and its progress towards maturity; and (3) *Taxonomy or Classification*, which deals with the arrangement and relationship of the beings whose structure has been ascertained. The science of *Functions* or *Physiology* is the companion science of M.

Morrellgunge, a town and port in the district of Jessore, Bengal, British India, 96 miles E. of Calcutta, situated in the

Sunderbunds on a creek of the Haringhata river, one of the larger mouths of the Ganges. It was founded in 1850 by Messrs Morrell, who took a lease from Government, and have reclaimed 20,000 acres from the primeval jungle. M. was declared a port, and buoyed by Government in 1869. It can be visited safely by large ships. Rice is the great export.

Morris, Rev. Richard, one of the best English scholars of the age, was born at Bermondsey, Southwark, September 8, 1833, and educated at St. John's College, Battersea. In 1869 he became lecturer on English literature in King's College School, and in 1871 was made curate of Christ's Church, Camberwell. He was elected President of the Philological Society in 1874, and in the same year received the honorary degree of M.A. from the University of Oxford. No man has done more—perhaps none so much—to make English a liberal and learned study. The influence of his work is beginning to be felt in every great public school in England and Scotland; and when the inevitable day has arrived in which men will admit that their native tongue is not only the base, but the crown of linguistic study, to which other languages, whether superstitiously called 'classical' or stupidly named 'modern,' are merely ancillary, the great merit of M.'s labours will be amply acknowledged. Besides editing Hampole's *Pricke of Conscience*, *Early English Alliterative Poems*, *Sir Gawayne and the Green Knight*, *The Story of Genesis and Exodus*, *The Aenbite of Inwyt*, *Old English Homilies* (2d series), *Cursor Mundi*, *Specimens of Early English*, *Chaucer's Poetical Works*, *Selections from the Canterbury Tales*, &c., he has written *The Etymology of Local Names* (1857), *Historical Outlines of English Accidence* (1872), *Elementary Lessons in Historical English Grammar* (1874), and *Primer of English Grammar* (1875).

Morris, William, an English poet, born in 1834, is the son of a wealthy merchant, and was educated at Forest School, Walthamstow, Marlborough College, and Exeter College, Oxford. He studied painting, but early devoted his attention to house decoration, a business he has been engaged in since. M. has written *Defence of Guinevere* (1858), *Life and Death of Jason* (1867), *The Earthly Paradise* (4 vols. 1863-71), *Love is Enough* (1873), *Translation of Virgil's Æneid* (1876), *The Story of Sigurd the Volsung and the Fall of the Niblungs* (1876). Through all his poems, especially the *Earthly Paradise*, there breathes a voluptuous indolence, and shines a glamour of sensuous delight that palls on the appetite for very richness.

Morrisania, a town of Westchester county, New York, U.S., on the Harlem River, is connected with New York by rail and by a fine suspension-bridge. Attached to the county and city of New York in 1874, it has twenty churches, many schools, an academy and convent, and is a favourite residence of the business men of the great city. Pop. (1870) 19,699.

Morris Dance, or **Morrice Dance** (corrupted from *Morisco*, or *Moorish dance*), a fantastic dance common in the middle ages, which is said to have been originally derived from the Moors, and was introduced into England probably from France or Flanders, under the early Tudor kings. In England it was long an important element of holiday amusement, and it still lingers on here and there in country districts. In the M.D. the hobby-horse, or a dragon, with Robin Hood, Maid Marian, Friar Tuck, The Fool, and the Queen of the May were the chief characters represented. Bells were fastened to the feet of the performers.

Morrison, Robert, D.D., the first Protestant missionary to China and an accomplished Chinese scholar, was the son of a lastmaker, and was born at Morpeth, January 5, 1782. He was trained at the Independent College, Hoxton, and at the College of the London Missionary Society at Gosport. After devoting much time to the study of Chinese, he was sent to Canton in 1807, where he combined zealous missionary labours with the duties of translator to the East India Company's factory. In 1812 he published *Hora Sinica* (translations from popular Chinese writings), in 1814 a translation of the New Testament into Chinese, in 1819 of the Old Testament, in 1822 his great *Chinese Dictionary* in 6 vols., and in 1825 *The Chinese Miscellany*. M. accompanied Lord Amherst to Peking as interpreter in 1817, and paid a visit to England in 1824-26. He died at Macao, August 1, 1834. His widow published in 1839 *Memoirs of the Life and*

Labours of Robert M. See also Medhurst's *China, its State and Prospects*.—**John Robert M.**, son of the preceding (born 1814, died 1843), was a member of the Legislative Assembly of Hong Kong, and author of a useful manual, *The Chinese Commercial Guide*.

Morristown, capital of Morris county, New Jersey, U.S., on the Whippany River, 31 miles W. of New York by rail. It has eight churches, the Speedwell Ironworks and stores, a public park, and three weekly newspapers, and is much visited by New-Yorkers during summer. Pop. (1870) 4398.

Morse, or **Walrus** (*Trichecus Rosmarus*), a genus of carnivorous mammalia represented by a single species, inhabiting the Arctic seas. This animal is included with the seals in the division *Pinnipedia*, or that in which the feet are converted into swimming paddles. Its chief characters are found in the disposition of the teeth. There are six upper and four lower incisors, but these are said by Owen to disappear while the animal is still young, with the exception of the outermost pair of the upper jaw. The canine teeth of the upper jaw form tusks, which may measure 15 or 16 inches in length, and are used by the animal to aid it in climbing upon the ice. Three molar teeth of simple form occur on each side of the upper jaw, and four molars on each side of the lower jaw. Some regard the foremost lower molar as a canine. The head is large and the muzzle prominent, the upper lip being provided with large bristles. The M. is not polygamous, like the seals, one male mating with one female only. The average length of the M. is about 12 or 13 feet, but specimens of 15 feet are by no means uncommon. The black skin is sparsely covered with dark brown or blackish hairs. These animals produce but one young at a birth, and both parents appear to regard their progeny with care and affection. They progress on land with a clumsy gait, but when alarmed contrive to move towards the sea with considerable speed. When brought to bay they defend themselves courageously with their long tusks. They are found in large herds, numbering several thousands in some cases. They are hunted for the sake of the skin, the fat, and especially the ivory of the tusks, which is very close-grained and white. The Eskimo value the M. exceedingly for the number of useful products obtained from all parts of its frame. Fossil remains of the M. occur in a fragmentary state in deposits of the Tertiary age. The name 'M.' is derived from the Russian *Morss*; *Walrus* is the Ger. *waltruss*, 'whale horse'; and *Rosmarus*, its specific appellation, comes from the Norwegian *Rosmar*, meaning 'sea-horse.'

Morse, Samuel Finlay Breese, one of the inventors of the electric telegraph, was born at Charlestown, Massachusetts, April 27, 1791. He studied art in London, 1811-15, after which he settled in America as a portrait painter. In 1835 he exhibited his telegraph at work at New York, and the admirable ingenuity and simplicity of his system attracted widespread attention. Its first adoption on a large scale was between Washington and Baltimore in 1844, and thereafter it became universal throughout the States and in a great part of Europe. It was introduced into Germany in 1851, and in 1857 several European states presented the inventor with a purse of 400,000 francs. The system is the alternate magnetising and unmagnetising of a bar, which causes a point to mark dots and scores on a travelling slip of paper. M. died in New York, April 2, 1872. See his *Life* by S. J. Prince, D.D. (New York, 1875).—**Sidney Edwards M.** (1794-1871), brother of the preceding, a journalist and geographer, invented a system of printing maps, called by him *cerography*.

Morshansk', a town of Russia, government of Tambov, on the Tzna, an affluent of the Oka, 250 miles S.E. of Moscow by rail. It has manufactures of cloth, soap, and tallow, and considerable trade in corn and cattle. Pop. (1870) 19,504.

Mortality, Laws of. The L. of M. are ascertained by analysing and collating statistics of life and death, the value of the deductions being in relation to the accuracy and extent of the data. While accuracy of registration is an essential condition, the greater the number of facts registered affords us the more certain means of arriving at correct deductions. In the early part of the 17th c., John Graunt of London published his *Natural and Political Observations on the Bills of Mortality*, and in 1693 Dr. Halley published the celebrated *Breslau tables of*

mortality, preceded, however, by the investigations of Pascal in France, and De Wit in Holland. In 1713 Bernoulli's work was published, and in 1742 Dr. Price published his tables of mortality for London. In 1746, M. Deparcieux published his *Essai sur les Probabilités de la Vie Humaine*, in which, from computations based upon the registers of different religious houses, he showed for the first time that female life is superior to male. In 1770, Dr. Price published his *Observations and Reversionary Payments*. The tables most generally used by assurance and annuity offices in this country are the following:—I. The Northampton Tables (Dr. Price's), based upon the register of burials in the parish of All Saint's, Northampton, 1735–80. II. The New Northampton Tables, numbers 1 and 2, constructed by Dr. Farr. No. 1 was deduced from a comparison of the deaths during 1838–44 with the census returns of 1841. No. 2 is based upon the deaths alone, in Northampton, during the 7 years 1838–44, and agrees almost exactly with that of Dr. Price; the mean duration of life, according to the two tables, respectively being 24.88 and 25.18 years, while according to No. 1 New Northampton it is 37.5 years. III. The Carlisle Tables, constructed from observations made by Dr. Heysham at Carlisle, 1780–87. IV. The Government Tables, computed by Mr. Finlaison on the lives of 22,000 nominees for Government annuities. V. The English Tables, Nos. 1 and 2, the former being deduced from the living by the census of 1841, and from the deaths at corresponding ages in the same year; and the latter from the living in 1841, and from the deaths in the seven years 1838–44. Both are based on the recorded ages of 15,913,148 living persons, and No. 2 on 2,436,648 deaths. The observations were taken on the plan recommended by Professor De Morgan and Mr. Griffith Davies, and probably give the results of the average mortality of England more correctly than those previously published. VI. The Experience Tables, Nos. 1 and 2. The tables, No. 1, were prepared by a committee of eminent actuaries, on the data afforded by the combined experience of 17 life-assurance offices, the labours of the committee having extended from 1838 till 1843. The data were derived from 83,905 policies, of which 40,616 were distinguished by denoting the sex of the lives assured, and by classing them into town, country, and Irish assurances. The Experience Tables, No. 2, sometimes called the Twenty Office Experience Tables, were commenced in 1862 and completed in 1869. In 1864, about 20,000 cards were issued to 20 offices, English and Scotch, requiring the following details, the oldest office being the London Assurance (1720). The particulars required on the English card were—policy number, life, British, Irish, or foreign, healthy or diseased, year of entry, year of exit, age at entry, age at exit, mode of exit, cause of death, and remarks. The Scotch card distinguished between the English and Scotch lives. The date to which the observations were carried was generally to the end of 1863, and the total number of entries, 160,426, was regarded as sufficient to allow of several valuable classes of tables to be formed. The four great divisions into which the data was reduced were the following:—(1.) Healthy lives, male; (2.) healthy lives, female; (3.) diseased lives, male and female; (4.) lives exposed to extra risk from climate, occupation, &c. The following table shows the numbers living at decennial periods out of 10,000 entering each class at age 10:—

Age.	Living out of 10,000. Entering at Age 10.				Carlisle Tables.	Experience Tables, No. 1.
	Healthy Males.	Healthy Females.	Healthy Males and Females Combined.	Diseased Males and Females Combined.		
10	10,000	10,000	10,000	10,000	10,000	10,000
20	9,616	9,408	9,554	9,679	9,427	9,327
30	8,987	8,519	8,904	8,548	8,734	8,609
40	8,223	7,574	8,128	7,544	7,856	7,805
50	7,274	6,620	7,133	6,426	6,806	6,952
60	5,808	5,535	5,847	4,832	5,639	5,597
70	3,793	3,799	3,805	2,785	3,717	3,584
80	1,392	1,464	1,411	898	1,475	1,329
90	150	186	159	57	220	132

The above table shows that at the age of forty the diseased lives and the healthy female lives show nearly the same decrement; but after that age the diseased lives rapidly diminish by death, whilst the healthy female lives are almost exactly the same as the healthy males.

The following table shows the *expectation* of life in each class, at decennial ages, in comparison with that shown by other well-known tables:—

Age.	Healthy Males.	Healthy Females.	Healthy Males and Females Combined.	Northampton.	Carlisle.	Davies, Equitable.	English, No. 1.	Experience, No. 1.
10	50.3	48.2	45.6	39.7	48.8	48.8	47.4	48.4
20	42.1	40.9	39.8	33.4	41.5	41.0	40.0	41.5
30	34.7	34.6	31.0	28.2	34.3	33.9	33.6	34.5
40	27.4	28.2	24.7	23.0	27.6	27.4	27.1	27.3
50	20.3	21.6	18.3	17.9	21.1	20.8	20.5	20.2
60	13.8	14.9	12.6	11.2	14.3	15.0	14.0	13.8
70	8.5	9.1	8.2	6.6	9.2	9.8	8.7	8.5
80	4.3	5.6	5.0	4.7	5.5	5.3	5.0	4.9
90	2.4	3.3	4.1	2.4	5.3	2.6	2.7	2.1

From the above table it will be seen that the improvement in the latter part of female life is such that though at the age of ten the female expectation is only 48.2, whilst that of healthy males is 50.3, yet at age 30 the expectation is nearly the same for both sexes; and after that age the female expectation is considerably higher at all ages. The following table shows the annual mortality, per estimate, at the chief quinquennial periods of life.

HEALTHY LIVES—MALE AND FEMALE COMBINED.

Age.	Exp. No. 2, unadjusted.	Exp. No. 1.	Carlisle.
15 to 19	.54	.71	.68
20 " 24	.73	.75	.70
25 " 29	.73	.80	.82
30 " 34	.85	.88	1.01
35 " 39	.97	.97	1.09
40 " 44	1.09	1.10	1.11
45 " 49	1.36	1.36	1.44
50 " 54	1.72	1.80	1.52
55 " 59	2.35	2.48	2.20
60 " 64	3.38	3.52	3.68
65 " 69	4.90	5.14	4.45
70 " 74	7.23	7.54	6.97
75 " 79	10.92	11.03	10.54
80 " 84	15.44	16.01	13.86
85 " 89	22.50	23.46	19.92
90 " 94	29.65	37.23	28.61

The mortality experience of the leading offices of the United States is now in process of being collected and compiled, under the superintendence of a committee of the Chamber of Life Insurance. See *The Insurance Cyclopædia*, by Cornelius Walford, London and New York, vol. iii., 1874, *et seq.*, and the *Assurance Magazine*.

Mortar, a short piece of ordnance of large calibre for discharging shells at an angle of 45° or thereby, in siege operations. It owes its name to a resemblance in form to the vessel called a mortar (Lat. *mortarium*), in which solid substances are pounded. The M., invented in the 14th century, was the earliest of European firearms. It was built up of longitudinal bars of wrought iron, hooped and strengthened with iron bands, without trunnions, while blocks of wood, hollowed out, served as a bed to fire it from. Afterwards the M. was cast with trunnions, an improvement that enabled it to rest firmly and steadily in its bed, and facilitated its elevation to any angle. Several sizes of mortars, for land or sea, are in use in the British service. The largest M. in the sea service is 13 in. calibre, 64 in. long, and 5 tons in weight. The 13-in. M., for land service, weighs 36 cwt., and measures 40 in. in length. The other sizes in use are 10 in. and 8 in. calibre. Land-service mortars are mounted on travelling carriages, which, deprived of their wheels, form steady M. beds. A 36-in. M., designed in 1858 by Mr. Mallet, to throw a shell weighing 2481 lbs., may be seen at Woolwich Arsenal.

Mortars used for cementing building stones together, and for plastering walls, are of two kinds—1, those which, like ordinary mortar, set and harden by exposure to the air; and 2, those that set and harden without the assistance of the atmosphere and indurate under water, hence termed *hydraulic M.* Ordinary building mortar is made of common or rich lime, mixed with pit or river sand or fine gravel, in the proportion of 3 parts of sand to 1 part of lime, and moistened with water to form a paste. The pure limestone is first calcined to expel carbonic acid, and the product, called quicklime, is *slaked* with water, which causes a violent evolution of heat, and a crumbling to a bulky powder of the hydrated lime. Ordinary M. harden on account of the absorption of carbonic acid from the atmosphere; in fact, the lime tends to revert to its original condition of a carbonate. For internal plaster work, as of walls and ceilings, the addition of tanyard hair is made to ordinary mortar to cause it to adhere to the laths. Silica and alumina are essential components of the stones used for making hydraulic mortar. Impure limestones containing clay (silica and alumina, admixed with oxide of iron), magnesia, and other substances, slake with different degrees of readiness and energy, and the slower and less violent the action, the better is the lime adapted for building under water. *Eminently hydraulic limes* are obtained from limestone containing from 20 to 30 per cent. of clay and other impurities, and M. prepared from them set in 3 days, and become hard in 1 month. Limestones with 12 to 20 per cent. of impurities yield *hydraulic limes*; while limes of *feeble hydraulicity* are procured from limestones containing from 8 to 12 per cent. Hydraulic limestones, found chiefly in the Lias and Lower Chalk formations, are not abundant in Great Britain. Their calcination and the slaking of the resulting limes require to be carefully conducted. Fine clean sand ($\frac{1}{2}$ to 2 parts to 1 of lime) is added to form the mortar. Hydraulic lime is prepared artificially on a large scale by mixing clay with rich lime, and calcining the mixture. The proportions depend on the purity of the ingredients; but 1 part of dry clay to 4 parts of rich unslaked lime (or 7 parts of carbonate of lime), may be taken as a fair proportion. Pozzuolana and trass—volcanic products—containing much silica and alumina, were formerly much used in England instead of clay. The setting under water of hydraulic M. is due to the formation of hydrated silicates of lime and alumina, the silicic acid having during calcination been so modified that it subsequently unites with the lime.

Hydraulic Cements, popularly so called, are prepared chiefly from argillo-calcareous nodules, in which a larger proportion of clay is present than in hydraulic limes. The stones are calcined, ground to powder, and mixed with water without slaking, and the resulting cements harden quickly in water without admixture of any substance. Of English cements of this kind, the varieties known as Parkers' (Roman), Medina, and Atkinson's enjoy a high reputation. The stones from which they are made are found at Harwich, Sheppey, Yorkshire, Isle of Wight, &c.

Portland Cement (named from its resemblance in colour to Portland stone), is an artificial hydraulic lime prepared from chalk (75 to 80 per cent.) and diluvial clay (20 to 25 per cent.), obtained in the Thames and other river basins. The ingredients are ground under water, and the sediment is dried, calcined, and reduced to powder. Portland cement is the strongest hydraulic mortar known, and from it concrete is largely made.

Selenitic Mortar or Cement, recently invented and largely used in plaster work, consists of hydraulic lime, anhydrous gypsum, and sand. The gypsum (sulphate of lime) promotes the setting of the mortar, and enables repeated coats of plaster to be applied within from twenty-four to forty-eight hours. Plaster of Paris (q. v.) is the basis of several other cements used for internal decoration of dwellings. Keene's cement is prepared by saturating plaster of Paris with an alum solution; the plaster is then dried, recalcined, and ground. In Parian cement the plaster is soaked in a borax solution, and in Martin's, in pearl ash.

Mastics are oleaginous cements, compounded of brick-dust, clay, litharge, or other materials, with oil. They are seldom used in bulk, being chiefly applied to the exposed joints of masonry.

Mort d'Arthur. The, is one of the romances of the Arthurian series. (See ARTHUR.) Up to the time of Geoffrey of Monmouth (12th c.) no author mentions the death, very few even the life, of the British warrior-prince. Nennius leaves him victorious after a succession of battles, but in the Chronicle of

Geoffrey (Lib. xi. cap. ii.) occurs the following curious passage:—'And even the renowned King Arthur himself was mortally wounded; and being carried thence to the isle of Avallon to be cured of his wounds, he gave up the Crown of Britain to his kinsman Constantine, the son of Cadur, Duke of Cornwall, in the five hundred and forty-second year of our Lord's incarnation.' This is perhaps the nucleus of the splendid romance of the medieval poets, which exists in various forms and in several languages, French, English, German, &c. One English version of the 15th c., from an MS. in the Harleian Library, was printed by the Roxburghe Club in 1819, and another by Mr. Halliwell from an MS. in the library of Lincoln Cathedral in 1847. Sir Thomas Malory's prose version is only a compilation, but executed with such quaint simplicity and pathetic power that Tennyson in his magnificent reproduction, which has familiarised Englishmen with the legend of Arthur's death, has often availed himself of the very words of the ancient knight.

Mortgage is in English law a pledge of land or other real property, in security of a loan. The borrower is called the mortgagor; the lender is called the mortgagee. A M. is often effected by merely depositing the title-deeds of a property; and, if a memorandum accompanies the deposit stating its object, equity will consider it a M.; and should occasion arise will give a decree for sale of the property. When no explanatory writing accompanies the deposit, the lender can only apply to a court of law for his money, retaining the title-deeds till he is paid. It has become the practice of late years to insert in a deed of M. an absolute power of sale, in case of breach of the condition of the deed.

If any person mortgage his estate a second time, and do not inform the postponed mortgagee in writing of the prior M. and of every incumbrance which he has voluntarily brought upon the estate, the postponed mortgagee holds the estate as a purchaser free from the *Equity of Redemption* (q. v.). The rule of equity is that a second mortgagee, who has the title-deeds, not having had notice of a prior incumbrance, shall be preferred; because the negligence of the first mortgagee in lending the money without taking the title-deeds enables the mortgagor to commit a fraud. It is settled law that if a third mortgagee, who at the date of his M. had no notice of the second, purchase the first M., even pending a bill filed by the second to redeem the first, both the first and third shall be paid out of the estate, before any share of it can be appropriated to the second. The reason given for this is that the third by thus obtaining the legal estate has both law and equity on his side, which supersede the mere equity of the second. 3 and 4 Vict. c. 55, amended by 8 and 9 Vict. c. 56, enables the owners of settled estates to delay by M. the expense of draining them. For Scotch law, see BOND.

Mortification, in Medicine. See GANGRENE.

Mortification, a term of Scotch law denoting a gift of land for charitable or public use. It is usually conveyed to trustees to be held by them *bleuch* or *in Feu* (q. v.).

Mortis Cau'sa Deed is, in Scotch law, a deed to take effect on the death of the maker. In Scotland, heritage (or real estate) cannot be conveyed by will. The usual mode of devise is therefore by deed of conveyance in the usual form, reserving the liferent of the maker, who keeps possession of the deed until his death. See DELIVERY OF A DEED.

Mortmain, Statutes of. These are English statutes passed to prevent priests frightening dying persons into conveying their lands for charitable or ecclesiastical purposes. The statute 9 Geo. II. c. 36 enacts that to be valid such a conveyance must be made twelve months before the death of the donor, before two witnesses, and be enrolled in the Court of Chancery within six months after execution. The deed must bear to have immediate effect, and must reserve no interest to the donor. The Act applies only to land in England.

Morton, a family that sprang from the Douglasses. James Douglas, Lord of Dalkeith, was created a peer in 1458 by the title of Lord Aberdour and Earl of Morton. James, third Earl, having no male issue, entailed the family estates and honours to his son-in-law, James Douglas of Pittendreich, who became chancellor under Mary, succeeded Murray as Regent, and after showing himself a true statesman in sagacity and bravery, but a cruel soldier, a corrupt judge, a hypocrite, and a profligate, was beheaded at Edinburgh, 2d June 1581, by the

Maiden, an instrument he had himself introduced to use. The earldom then reverted to John, Lord Maxwell, who, when the Act of Indemnity was passed in 1585, was created Earl of Nithsdale, while the Morton title devolved upon Archibald Douglas, eighth Earl of Angus. The eighth Earl of Morton was Sir William Douglas of Lochleven. William, eleventh Earl, died without issue, and the honours passed to his uncle, Sir James Douglas of Smithfield. George, eighteenth Earl, was made a peer of Great Britain in 1791, as Baron Douglas of Lochleven, but as he died childless the British barony expired, his cousin, George Sholto Douglas, becoming Earl of Morton. His son, Sholto John Douglas, present Earl of Morton, a representative Scotch lord, was born April 13, 1818, married, first, Helen, daughter of James Watson, Esq. of Saughton, 24th January 1844; and, secondly, Alice Alaine Carolina, daughter of the Earl of Durham, 7th July 1853. He succeeded his father, 31st March 1858.

Morton, Henry, born at New York, December 11, 1836, graduated at the University of Pennsylvania (1857), and was successively appointed Professor of Chemistry at the Philadelphia Dental College (1863), secretary of the Pennsylvanian Franklin Institute (1864), Professor of Chemistry in the University of Pennsylvania (1869), and President of the Stevens Institute of Technology at Hoboken, New Jersey (1870). Besides sixteen *Lectures on Light* (1867), which excited considerable attention in the learned world, M. is author of numerous able papers in the *Chemical News*, *Philosophical Magazine*, and other scientific journals.

Morton, John, was probably born at Milborne St. Andrew, in Dorsetshire, about 1420, and proceeded from Cerne Abbey to Balliol College, Oxford, where he graduated LL.D., and became principal of Peckwater Inn (1453). Introduced by Cardinal Bouchier to Henry VI., he had been made a privy councillor, rector of Bloxworth, chancellor of Cornwall, and subdean of Lincoln (1450). He was present on the Lancastrian side at the battles of Towton and Barnet, but after the defeat of Tewkesbury (1471) gave in his adhesion to Edward IV., and by him was appointed Master of the Rolls (1472), and Bishop of Ely (1479), with a host of minor preferments. Edward's death, however, was followed (June 13, 1483) by the famous 'strawberry scene' of Shakespeare's *Richard III.*, and by M.'s imprisonment in Brecknock Castle. Escaping to Ely, he passed over to Flanders, and there received the news of the victory of Bosworth (1485). On his return to England his attainder was reversed, and he was created lord chancellor and archbishop of Canterbury (1486), a cardinal (1493), and chancellor of Oxford (1494). He died at Knowle, in his native county, October 12, 1500. An eminent lawyer, with a prodigious memory, full of energy, but of polished manners, cursed with a besetting sin of avarice, yet princely in bestowing—such is the character that may be gathered from his life, and from the first book of the *Utopia* of Sir Thomas More, who was page in his household (1494-97). See vol. v. of Hook's *Lives of the Archbishops of Canterbury* (Lond. 1867).

Morton, Samuel George, an American ethnologist and craniologist, born at Philadelphia, January 26, 1799, graduated in medicine at the University of Pennsylvania (1820), and of Edinburgh (1823); was appointed Professor of Anatomy in Pennsylvania Medical College (1839-43), and President of the Academy of Natural Sciences (1840); and died at Philadelphia, May 15, 1851. M. was author of *Human Anatomy* (1839), *Crania Americana* (1839), and *Crania Egyptica* (1844), besides a host of papers on ethnology, chemistry, geology, &c. In the *Types of Mankind*, published by Nott and Gliddon in 1854, which is partly made up of selections and adaptations from M.'s unpublished papers, there is an appreciative *Notice of the Life and Scientific Labours of M.* by Dr. Henry S. Patterson.

Mortuaries, in England, are customary gifts claimed in many parishes by the incumbent on the death of his parishioners.

Mosaic (Fr. *mosaïque*, from Ital. *mosaico*, Lat. *musivum*, Gr. *mouseion*, 'the temple of the Muses,' which was finely decorated), a name used to denote several varieties of decorative work, all produced by embedding together fragments or small pieces of variously coloured hard material so arranged as to produce any predetermined geometrical or pictorial pattern. M. work and inlaying approach closely to each other, but in the case of the latter, accurately cut pieces of the inlaying substance

are fitted in, and occupy entirely a definite portion of any design or figure. The applications of M. work are varied, and the materials employed embrace coloured marbles and other stones, precious stones, glass, and pottery. M. is employed for pavements and floors, for the decoration of walls of churches, and public and private buildings, and, in its minute fine forms, for decorating small pieces of furniture, brooches, studs, and for other similar purposes. The work is of very ancient origin, having been practised by the early Assyrian and Egyptian races. It passed into Greece, whence it was carried to Rome, where about the beginning of the Christian era it attained great prominence and perfection. At a very early period it became a favourite means of producing decorative pictures for ornamenting the walls of churches, whence the art became peculiarly associated with Byzantine architecture, a relation which continues to the present day in the prominence of M. work in the Russian and Eastern churches. Modern M. work, leaving out of account simple tessellated or M. pavements, embraces the production of large works in glass tesserae for wall decorations, chiefly carried on in Venice and St. Petersburg, and the fabrication of minute work in fine coloured and precious stones—known as Roman and Florentine mosaics. In the atelier of a M. artist the glass employed embraces many thousands of different shades, and the copying of a work of art in M. demands the greatest care, patience, and skill; but once fabricated, the M. picture is practically imperishable.

Mosaic Wool, a method of producing imitation tapestry and complex pictorial effects in wool for rugs, sofa-covers, hangings, &c., introduced and some time worked by Messrs. Crossley of Halifax. It consisted of assorting bundles of woollen yarn so that when cut across, the ends of the yarn showed the desired pattern. The cut ends of such assorted bundles were caused to adhere to a stout backing by means of a solution of india-rubber and when shorn across so as to leave any requisite depth of pile, the pattern of course came out on the surface. It is now entirely superseded by other processes. See CARPET.

Mosaylima ('Little Muslim') was a contemporary and rival of Mohammed, belonging to the Arab tribe of the Banu Hanifah, who was known as a religious teacher before the latter had assumed his mission. In the 9th year of the Hejrah he headed an embassy which had been sent by his tribe to Mohammed, and professed himself a Muslim. But the next year he set up for a prophet himself, and published revelations in imitation of the Koran. Having gained a considerable body of adherents from his tribe, he sent a request to Mohammed that he would share his power with him, to which it is said that Mohammed returned an insulting refusal. On the other hand there is no doubt that Mohammed made considerable concessions to M., and recent investigators think there is reason to believe that he intended at his death to nominate him his successor, having secretly done so before. After Mohammed's death (11 A.H.) Abu Bekr sent an army to crush M., and a battle was fought in which M. was slain and his army defeated, whereupon his adherents submitted and embraced Mohammedanism. See Muir's *Alahomet* (new ed. 1877).

Mosch'eles, Ignaz, pianist and composer, was born of Jewish parents at Prague, 30th May 1794. He was a precocious child, and at the age of eleven was the best pianist in his native city. In Vienna he studied under Albrechtsberger and Salieri. After a professional tour over all Europe, he took up his residence in London in 1820, where he was for more than twenty years professor in the Royal Academy of Music and conductor of the Philharmonic Concerts. He translated Schindler's *Life of Beethoven* into English in 1841. At Mendelssohn's suggestion he accepted the musical professorship in the Conservatoire at Leipzig in 1846. He died 10th March 1870. M. published many beautiful concertos, sonatas, fantasias, and studies. He was unrivalled as a pianist in his own pure classic style. See *Aus Moscheles' Leben*, by his widow, 2 vols. (Leips. 1872-73), translated into English by A. D. Coleridge (Lond. 1873).

Mos'cow (Russ. *Москвѣ*, Ger. *Moskau*), the former capital of Russia, and now the chief commercial and industrial city of the empire, is situated in a fertile plain surrounded by low hills, on the rivers Moskva and Jausa (frozen over from 20th November to 15th April), 400 miles S.E. of St. Petersburg by rail. From the Sparrow Hills to the S. the city has a singularly picturesque

appearance, with its gilt domes, coloured spires, and greenhouse-roofs, its old Byzantine buildings contrasting with modern Renaissance structures, its crowded, dingy quarters intersected by Parisian boulevards, and alternating with green, open spaces, where the inhabitants lead a country life. Although the streets have been laid out on a preconceived plan, and although a few have been Europeanised, there is an almost total absence of anything like paving, and, strictly speaking, there is no street architecture,—no regularly-built terraces, crescents, or squares; the greatest incongruity prevails, and wretched hovels rise by the side of splendid palaces. But M. as the great commercial capital of Russia is rapidly improving and increasing. As the heart of Russian tradition 'it treasures the ancient churches, with the tombs of grand princes and holy martyrs, the palace in which the Tsars of Muscovy lived, the Kremlin, which resisted—not always successfully—the attacks of savage Tartars and heretical Poles, the venerable Icons that many a time protected the people from danger, the block of masonry from which on solemn occasions the Tsar and the Patriarch addressed the assembled multitude' (Mackenzie Wallace). The city, girt by a dam and moat, has a circumference of 23 miles, and consists of four distinct parts, exclusive of the six Slobodi or suburbs, which are extensive, and contain many mansions, monasteries, hospitals, &c. (1) The Kremlin, the core of the city, occupies an elevation on the N. bank of the Moskva, and is enclosed by a heavy stone wall surmounted by towers, dating from 1367. Here are the palaces of the Czar, the Patriarch, and the Holy Synod; the arsenal (1702), with its grand trophy of 875 cannons abandoned by Napoleon in 1812; the Cathedral of the Assumption (1325–1475), where the Czar is crowned, with its columns of porphyry and jasper, its floor paved with agates and cornelians, and its walls enriched with costly mosaics. Other notable buildings in the Kremlin are the Cathedral of St. Michael (1507, restored 1732), containing the tombs of all the Czar's prior to Peter the Great; and the tower of Ivan Veliki, 270 feet high, supporting a gilded dome 37 feet high, and a peal of 32 bells. On a pedestal adjoining Ivan Veliki is the famous Czar Kolokol (king of bells), the largest bell in the world, weighing 193 tons. (2) Kitaigorod (*i.e.*, Chinese town), to the E. of the Kremlin, and surrounded by thick walls, is the oldest part of M., and the great seat of trade. Here the streets and markets are crowded with merchants from the Western capitals and the remote countries of the East. The chief buildings are two cathedrals of the Defence of the Virgin and of the Mother of the Saviour, and the great bazaar containing 6000 booths. (3) Bjelgorod (*i.e.*, 'white town' from the colour of its former walls, which have given place to boulevards) encircles the Kremlin and Kitaigorod on three sides, and comprises many of the finer streets. In this quarter are the palaces of the governor and many nobles, the university, the founding hospital, the post-office, the theatres, and a celebrated drill-hall, 560–158 feet, affording scope for the movement of 2000 infantry, or 1000 cavalry. (4) Semljanoigorod ('earthen town,' from its having been formerly surrounded by an earthen wall) contains, besides schools and hospitals, many large factories, and is a great residence of the working classes. In 1868 M. was entered by 24 gates, and had 81 markets and squares, 11 fountains, 57 bridges, and 7 public gardens, 23 hospitals and medical charities, 27 other benevolent institutions for the reception of 65,000 persons. The places of worship amounted to 357, and of these 5 were cathedrals, 8 high churches, 3 Protestant, 2 Roman Catholic, and 2 Armenian. The university (founded in 1755) is attended by 1500 students, and has a library of 150,000 vols. There are 108 common schools for 20,000 children, and among the higher intellectual institutions are the museum, removed from St. Petersburg in 1861, and containing 150,000 vols., the ethnological museum, reflecting the life of the various countries of the empire, the Synodal library with its 900 Slav. MSS., an institute for Oriental languages (33 teachers and 200 students), a picture gallery, and military, dramatic, and art schools. M. is the centre of the Russian railway system, and is connected by water with the Baltic, the Black, the White, and the Caspian Seas. Its trade is chiefly in tea, corn, fur, hides, tallow, and metals. The greatest manufacturing city in Russia, its cotton, woollen, and silk factories, its dyeing, printing, and tanning works, its industries in silver, candles, iron-ware, &c., employ 9000 skilled workmen, 20,000 labourers, and 10,000 apprentices. The annual value of the industries is £4,300,000. Pop. in 1816, 166,515; in 1837, 348,562; and in 1871, 611,970. M. was founded in

1147, and was made the capital of Muscovy by Ivan I. in 1328. Thrice attacked by the Lithuanians (1368–72), it was sacked by Timur in 1381, and subsequently pillaged by the Tartars in 1451 and 1477. The massacre of Demetrius and his Polish adherents (the 'matins of M.') in 1606 was followed by the Polish occupation of the city, 1610–12. In 1812, M. had 252,609 inhabitants, but when it was entered (September 15) by Napoleon, he found it occupied by some 12,000, the fugitives having carried off all the treasure and valuables. A great fire, generally supposed to have been raised by order of the governor, Rostopchin, raged for seven days, and reduced a great part of the city to ashes, thus forcing the disastrous retreat of the French.—The government of M. is one-half cultivated and 38 per cent. under woods. It is the richest industrial part of Russia, containing as many as 75,313 artisans. Area, 12,552 sq. miles; pop. (1870) 1,678,784. See Schmitzler's *Moscou, Tableau Statistique, Géographique, Topographique, et Historique* (Peters. and Paris, 1834); Kohl's *Reise im Innern von Russland und Polen* (Dresd. and Leips. 1841); and Mackenzie Wallace's *Russia* (Lond. 1877).

Moselle, a name borne by still and sparkling wines made from grapes cultivated in the valley of the Moselle river. M. in its natural state is mild and acidulous, but the great bulk of it has an artificial 'muscatel' flavour imparted to it by admixture of a tincture of elder flowers, which also increases its alcoholic properties. Sparkling M., made at Koblenz, is esteemed for its peculiar bouquet, which is not unfrequently derived from the elder-flower.

Moselle (Lat. *mosella*), a river of France, and an affluent of the Rhine, rises in the Vosges, flows in a N.E. direction through Meurthe-et-Moselle, Luxemburg, and Rhenish Prussia, passing the towns Epinal, Metz, Thionville, Trier, &c., and joining the Rhine at Koblenz, after a sinuous course of 330 miles. The former department of M. was in part ceded to Germany after the late war, and in part taken to form the department Meurthe-et-Moselle (q. v.) in 1871.

Moses (a name which has been variously explained as Coptic, 'saved from the water'; Heb. 'the drawer out,' *i.e.*, 'the leader, deliverer'; Egypt. 'the child,' &c.), the great Jewish lawgiver, was born in Egypt at the time when the Hebrews were subjected to a most oppressive slavery by the Egyptians. His parents, who belonged to the tribe of Levi, were Amram and Jochebed, whose whole family were M., a brother Aaron, three years older (Ex. vii. 7), and a sister Miriam, the eldest. Preserved by the devotion of his mother from immediate destruction at his birth, a fate which the Egyptians at the time imposed upon all the male offspring of the Hebrews, and next saved by an Egyptian princess from the Nile, on which he had been placed in a basket of papyrus when she could no longer conceal him, M. was brought up at Pharaoh's court (Ex. ii.), and 'was learned in all the wisdom of the Egyptians' (Acts vii. 22). For all that, his heart was ever with his oppressed brethren, and when grown to manhood (forty years of age, Acts vii. 23) he one day killed an Egyptian overseer who was beating a Hebrew, and finding that his deed was known he fled to the desert in the neighbourhood of Mount Sinai. There he became acquainted with a Shiekh (prince and priest), named Jethro, of one of the Midianite tribes inhabiting the region at that time, and marrying one of his daughters (Zipporah), spent other forty years of his life (Acts vii. 30) tending his father-in-law's flocks. At the end of that time Jehovah appeared to him in a burning bush, and commissioned him, under a promise of his support, to go to the help of his suffering brethren (Ex. iii.). Accompanied by his brother Aaron, who met him on the way, M. returned to Egypt and demanded that the Hebrews should be permitted to go out to the desert and celebrate a festival in honour of their God. This demand only brought more burdensome tasks and greater suffering upon them; and the permission was only granted after ten plagues had been inflicted on the land by the hand of M. (iv. 12). There is a remarkable likeness between these plagues and certain natural phenomena that occur in the country. Travellers tell us that the water of the Nile sometimes acquires a red colour and an offensive smell; that after its overflowing frogs often cover the fields in vast numbers; that gnats and great stinging flies breed in swarms in the deposited mud, and grasshoppers in countless numbers destroy the fields; that sometimes great damage is done by a hail-storm; and that there is a wind in the spring which sometimes raises such a quantity of fine sand from the

desert into the air that there is continuous darkness for some days. In the last of the plagues there is reflected, as it were, the conflict between the religions of the two nations. According to the religion of the Hebrews the first-born of man and beast belonged to Jehovah, and had either to be redeemed or offered to him. This notion of sacrifice was foreign to the Egyptian religion, and in the plague it was expressed that the unredeemed first-born of the Egyptians had to die.

When the people were at last permitted to depart (see EXODUS), M. led them out into the desert, across the Red Sea, and on to the peninsula of Sinai, where he received from the hand and mouth of God on the mountain, and gave to the people, a system of moral, political, and ceremonial law. Leaving Sinai he led them to the borders of Canaan, and then acted as their ruler and judge during the thirty-eight years for which they were doomed to wander in the desert. He himself was not permitted to enter Canaan with the rest, because he had rebelled against Jehovah (Num. xx. 12, xxvii. 14; Deut. xxxii. 51; cf. Ps. cvi. 33); so he died and was buried on the east of the Jordan, 'in the land of Moab,' at the age of one hundred and twenty (Deut. xxxiv. 5-7). Thus far the Bible narrative regarding the bare incidents of his life; but the chief interest and importance attach to the consideration of the part he played as a prophet and religious reformer. He regarded himself as a mere instrument in the hand of Jehovah for the deliverance of his brethren. This may have been quite consistent with his own consciousness, but yet it is not sufficient to explain his history; his own character and training must also be taken into account, as in the case of all other reformers. The great peculiarity of the position of M. was, that being a Hebrew he was brought up at the Egyptian court, where he must have become well acquainted with the political, social, and religious life of the Egyptians. The Hebrews at the time had fallen into Polytheism (cf. Josh. xxiv. 14; Ezek. xx. 5-9, xxiii. 19, 21, 27), but still they continued to adore a Supreme Deity, who was conceived of as a severe, unapproachable being, 'a consuming fire' (Gen. xvii. 1, Exod. vi. 3; *El Shaddai*, 'God Almighty,' the terrible, destructive One, Deut. iv. 24). Now for M., pondering among the solitudes of Sinai, with the misery of his brethren ever gnawing at his heart, the question was, who could help them if not their God? And would that God support him if he should try to deliver them? In the burning bush, which was not consumed, the revelation is made to him that *El Shaddai*, the terrible, the severe, is also Jehovah, the gracious protector of his people; at the same time an assurance is given to M. that he would protect his servant when he set out to their help. A special feature of the work of M. was that he connected the observance of moral precepts entirely with religion. Morality, according to the Egyptians, was under the oversight of the gods—e.g., Osiris was judge in the lower world; M. transplanted it to a still higher ground, and bound it up inseparably with religion. This, together with the new conception of Jehovah as above all other gods, and therefore to be worshipped alone (Exod. xx. 3), formed an epoch in the religious development of the Hebrews (see JEWS). That part of the law which is distinctively Mosaic is the Decalogue. Much of the mere ritual was undoubtedly derived from Egypt; other portions, e.g., the regulation of slavery, of blood-feud, of clean and unclean food, &c., were similar to those in vogue among the other Semitic tribes; but it is only in the sublime creed of the great lawgiver that we find God recognised as the Creator and Sustainer of the Universe, and as the living Guardian and Ruler of men, to whom they owe perpetual fealty and worship. It is this which gives a perennial freshness to the story of M.'s life, and breathes through the record an inspiration which no criticism can challenge, and which is 'subject neither to eclipse nor wane.' See Stanley's *Jewish Church* (2d ed., Lond. 1877), and M. in Smith's *Dict. of the Bible* (1863); Brugsch's *Aus dem Orient* (Berl. 1865); Kuenen's *Religion of Israel* (Lond. 1874-75).

Mosh'eim, Johann Lorenz von, born at Lübeck, 9th October 1694, graduated at Kiel (1719), became Professor of Theology at Helmstedt (1723), and at Göttingen (1747), where he died, Chancellor of the University, 9th September 1755. A masterly preacher—his *Predigten* (6 vols. Hamb. 1725-39) are fine examples of the rules prescribed by him in *Anweisung erbaulich zu predigen* (Erlang. 1760)—and an earnest and able historian, M. published no less than 161 different works, many of which have been translated into various European languages from the

original Latin in which they were generally composed. Of these may be mentioned *Institutiones Historia Ecclesiastica* (Helms. 1737-41; best Eng. trans. by Dr J. Murdock, 3 vols. New York, 1832), *Institutiones Historia Christiana Majores* (Helms. 1739), *Versuch einer unparteiischen Ketzergeschichte* (2 vols. Helms. 1746-48), and *De Rebus Christianorum ante Constantinum Commentarii* (Helms. 1753). See F. Lucke's *Narratio de J. L. M.* (Gött. 1837).

Mosk'wa, a river of European Russia, rises in the government of Smolensk, and has a winding course of 249 miles, first E. through the city of Moscow, then S.E. to the Oka, which it reaches below Kolomna, where, at the spring floods, it often rises 40 feet. Its greatest breadth is 525 feet (above Moscow 213). It is frozen from the beginning of November to the end of March. 1000 barges ply yearly on its waters. Its upper part is connected with the Volga by the M. Canal. Near its right bank, 70 miles W. by S. of Moscow, is Borodino (q. v.).

Mososau'rus, a genus of extinct lizards, of huge size, represented by species obtained from the cretaceous or chalk deposits. *M. Camperi*, from the Maestricht chalk, is a familiar example. *M. princeps* must have attained a length of 70 or 75 feet. The teeth were numerous, long, conical, and curved. They were not set in distinct sockets, but, as in existing lizards, were united by *anchylosis* or a bony union to the jaws. That the M. was of aquatic habits has been inferred from the shortness of the fore limbs and from the apparently flexible nature of the tail, while recent researches seem to show conclusively that the limbs were in the form of swimming-paddles. Allied genera are *Halisaurus*, *Leiodon*, and *Baptosaurus*; and in certain American examples of the group of *Mosasauroid* lizards, bony plates have been recognised.

Mosques (Ital. *moschea*, from Arab. *mesjid*), Mohammedan places of worship, are commonly rectangular buildings, surmounted by a dome (of Byzantine origin), and flanked by minarets (the Christian campaniles). In front, an open court contains a fountain for the prescribed ablutions; within, one sees neither altar nor benches, only a matted floor, with the *mimbar* or pulpit of the *imâm*, and the *kibleh* or niche on the Mecca side, towards which the faithful address their prayers. Lamps, arabesques, and verses of the Koran inscribed in golden letters are the only decorations of a mosque. Yet whole histories are often enshrined in its walls. As heathen temples had been converted into Christian churches, so these were in turn devoted by their Arab conquerors to the worship of Islam. Scrape off the white-wash that covers the walls of St. Sophia, the grandest of all M., and you would come to the icon of a saint or father of the Church. And so to-day in Spain or Hungary one sees churches that once were M., with, it may be, a cross on one minaret, on another a crescent.

Mosquito, the Spanish term for 'gnat,' applied to those species of the family *Culicidae* (order *Diptera* or Flies) which have the mandibles and maxillæ or jaws of lancet-shape, adapted for piercing the skin of the animals they attack. The larvae are active, and both larvae and pupæ inhabit water. The genus *Culex*, to which many species of M. belong, has a wide range of distribution, being found in Arctic as well as tropical regions. The sharp bristle-like mouth-parts are plunged into the body of the prey, and the blood is rapidly withdrawn. The irritation of M. bites was believed by Westwood to depend on some fluid ejected by the animals into the tissues; but no poisonous secretions are known to exist. The W. Indian M. (*Culex Mosquito*) resembles the common gnat, and abounds in tropical America. *Anopheles quadrimaculatus* (Say) is a large species of M., distinguished by two spots of light colour on each wing. It bites severely, and is said to hibernate in houses. It certainly appears

very early in spring. The M. is a dreadful pest in warm climates. Curtains of gauze and various other contrivances are used to protect sleepers from its attack.

Mosquitto Coast or **Mosquitia**, an ill-defined territory of Central America, extending along the Caribbean Sea, and lying between Costa Rica, Nicaragua, and Honduras. Its area is estimated at from 15,000 to 36,000 sq. miles, and its pop. at 10,000. The country is a great plain, watered chiefly by the Segovia and Escondido, and yielding rice, maize, manioc, cocoa, ginger, sarsaparilla, &c. In the swampy parts there are dense forests of mahogany and other fine timber and dye-wood trees. The inhabitants, mostly aboriginal Indians, are directly ruled by a chief who calls himself king of Mosquitia. The M. C. was under British protection from 1660 to 1859, when it was ceded to Honduras. The country was handed over by Honduras to Nicaragua in 1860, and is now (1877) claimed by New Granada.

Mosses (*Musci*) are an important and beautiful class of non-vascular cryptogamic plants, as a rule well marked by their peculiar habit and fruit. They are found in all parts of the world except the driest, ascending to mountain heights much beyond the limit of flowering plants, abounding in temperate perennially humid latitudes, and some among them growing immersed in water. In size they vary from almost microscopic to strong-stemmed species more than a foot high. The leaves are often narrow, of very thin or even membranous texture, and of simple structure. They are never lobed or divided, have a margin entire, or toothed, or sometimes thickened, and are without stomata. The colour is usually green, but in the Bog M. and a few others nearly white. They do not possess true roots, the nutriment being absorbed through root-hairs. Reproductive organs are of two kinds: the capsule containing minute spores produced from the fertilised female inflorescence (*archegonia*); and the *antheridia* or male inflorescence. The capsule (*theca* or *sporangium*) is lateral or terminal on the branches (*acrocarpus* or *pleurocarpus*), sessile, or on a fruit stalk (*seta*) of various shapes, indeli-cent, or bursting by four valves at the sides, or most commonly by a transversely deciduous cap (*operculum*) covered by a deciduous calyptra. When the operculum falls the mouth of the capsule is exposed. The rim is naked or crowned with one to three concentric rows of teeth-like or cilia-like appendages in sets of four or a multiple of that number (*peristome*). These are often brightly coloured and are hydroscopic. Spores numerous, escaping under the control of the peristome from the mouth of the capsule, green, yellow, or brown in colour simple or combined, without external covering or markings. The antheridia are oblong or linear stalked membranous sacs, mixed with jointed filaments (*perophyscs*), surrounded by whorls of leaves (*perigonia*), either axillary or terminal on the stems or branches. The sacs have open mouths, and contain a multitude of cells, each with an enclosed spiral filament (*antherozoid*) endowed with motion. The spores on germination produce a green conservoid-like mass of threads on which the bud is developed from which the young plant arises. The individual, if a monerous species produces bundles of archegonia and antheridia, and the former being fertilised by the latter gives rise to the capsule. If a dioecious species, the female and male organs are produced on different individuals. In fewer cases the two organs are intermixed in the same inflorescence. Besides the reproduction by spores, M. are also propagated asexually by gemmæ and by stolons.

M. may be divided into *Sphagnaceæ*—Bog M. with two kinds of spores, and *Bryineæ*, True M. with one kind of spore. The latter subdivide into *Andreaeaceæ*, where the ripe capsule opens by four longitudinal slits; *Phascaceæ*, in which the roundish capsule ruptures the calyptra laterally without rising it as a lid, and with no operculum; and *Bryaceæ*, in which the capsule is covered by a calyptra, and opens by throwing off an operculum. M. are not of much economic value, excepting that the different species of *Sphagnum* constitute a large portion of peat. The so-called Iceland Moss and Reindeer Moss are Lichens; the Irish Moss is a seaweed.

Mostar, capital of Herzegovina, 35 miles from the Adriatic coast, and 48 S.W. of Bosna-Serai, on the Narenta, which is spanned by a celebrated Roman bridge of a single arch 95 feet long. M. manufactures knives, sword-blades, fine silks, &c., and the vicinity produces excellent wine. Pop. 12,000.

Mo'sul, a town in the vilayet of Bagdad, Asiatic Turkey, on the right bank of the Tigris, opposite the ruins of Nineveh. Formerly the metropolis of the Mesopotamian Christians, and a place that supplied all Europe during the middle ages with fine cotton fabrics, it is now merely a station of the Eastern caravan trade. According to Marco Polo, M. gave its name to 'Muslins.' Pop. about 40,000, of whom some 15,000 are Christians, 1500 Jews, and the rest Mohammedans.

Motacilla. See WAGTAIL.

Motett (perhaps from Ital. *moto*, from its lively and varied character), originally a musical composition resembling the *Madrigal* (q. v.), but, later, one written for the Church. It preceded the *anthem* in the English Service.

Moth, the name given to such species of Lepidopterous insects as are nocturnal in habits; butterflies being in contradistinction named 'Diurnal' Lepidoptera (q. v.). This distinction, however, by no means holds good in all cases. Many moths fly about by day, and some are 'crepuscular,' i.e., active during twilight. In the typical moths the antennæ are bristle-like, while they may be comb-like (*pectinate*), or provided with side processes. When in a state of rest the wings are deflexed or horizontal; those of the butterflies being erect in repose. The front margins of the hinder wings are provided with *retinacula* or spines, which are lodged in a hook on the lower surface of the front wings; this arrangement serving to bind the wings together, and to aid in strengthening them in flight. The chrysalides of moths are, as a rule, smooth externally, and are frequently enclosed in cocoons. The crepuscular lepidoptera have tapering antennæ, and the wings are horizontal or only slightly inclined when in a state of repose. Moths are generally more robust than butterflies, and their colours are less brilliant. The chest or thorax is usually shorter. Among the more notable species are the Silk-M. or *Bombyx*, the larvæ or caterpillars of which furnish silk; the Sphinx M., Death's-head M., Goat M., Leopard M., Plume M., &c.

Mother Carey's Chicken, the sailor's name for the Stormy Petrel (*Procellaria* or *Thalassidroma pelagica*), a natatorial or swimming bird, belonging to the family *Procellaridae*. Its average length is 6 inches; its colour a sooty black, the edges of the tail-coverts being white. The petrel is found in the most stormy weather skipping rather than flying across the waves, keeping itself just above the surface of the sea. It breeds on northern coasts, laying but one egg of a white colour. The flesh is very oily, and it is said to be capable of ejecting an oily fluid from the mouth. 'M. C.'s goose' is the name given to the great black petrel (*P. gigantea*) of the Pacific Ocean.

Mother-of-Pearl is the brilliant internal or nacreous layer of certain shells belonging or closely allied to the oyster family. The principal varieties of the M.-of-P. shells of commerce are brought from Manilla, Singapore, Western Australia, and Sandwich Islands. The *Meleagrina margaritifera* is, from its size and thickness, the M.-of-P. shell *par excellence*. It is used for inlaying, and is formed into knife-handles, studs, buttons, boxes, and many other ornamental and useful articles. Several other shells displaying iridescent hues, as species of *Haliotis* and *Turbo*, have similar applications. The beautiful play of colours exhibited by M.-of-P. arises from a series of superficial microscopic furrows which decompose the light.

Motherwell, a town of Scotland, Lanarkshire, in the parishes of Hamilton and Dalziel, 15 miles E. by S. of Glasgow, and a junction on the main line of the Caledonian Railway. It is named from a celebrated 'Well of Our Lady,' and in its vicinity are extensive iron works and collieries. The West of Scotland Malleable Iron Work Company, the largest in Scotland, have their works here. A magnificent water supply, brought from 10 miles distant, was inaugurated on the 25th October 1877. Pop. (1871) 5852.

Motherwell, William, a Scottish poet and journalist, was born in Glasgow, 13th October 1797. From 1818 to 1829 he held the office of Sheriff-clerk Depute of Renfrewshire at Paisley, became editor of the *Paisley Advertiser* in 1828, and of the *Glasgow Courier* in 1830, both Tory newspapers, and threw himself into the keen political battles of the day with a passion which shortened his life. He died of apoplexy, November 1, 1835.

M.'s first volume was the *Harp of Renfrewshire* (1819), containing sketches of local poets during three centuries. It was followed in 1827 by his *Minstrelsy Ancient and Modern* (new ed. 1874), a work of permanent value, and in 1832, *Narrative and Lyrical Poems*. Some of these deserve to be immortal. In fiery force of heathen pride, not unrelieved by tenderness, the *Sword Chant of Thorstein Raudi* has never been surpassed; while *Jeanie Morrison* is perhaps the sweetest reminiscence of love and youth in the Scottish dialect. An edition of M.'s poems with a memoir appeared at London in 1849, another in 1858, and a third at Glasgow in 1866.

Moth'crwort, so called, says Parkinson, from its being 'of wonderful helpe to women in the risings of the mother,' is the name still retained for *Leonurus cardiaca*, one of a small genus of *Labiatae*. The plant is a native of Europe and portion of Asia, and is occasionally met with by hedge-sides and in waste places in Britain—generally near villages, and only existing as a remnant of old cultivation. The name M. has also been applied to *Artemisia vulgaris*; it, too, was formerly used as a herb in uterine diseases—a *matrumherba*.

Motion, Laws of, as enunciated by Newton, are necessary and sufficient for the establishing of the whole of dynamical science. They are three in number, and must be regarded as being deductions from observation and experiment.

Law I.—Every body continues in its state of rest or of uniform motion in a straight line, except in so far as it may be compelled by impressed forces to alter that state. In the words 'uniform motion' we are at once introduced to the fundamental conceptions of space and time, and are furnished with a method for measuring such. See SPACE and TIME. Further, this law, in telling the conditions under which there is no external force, supplies a criterion by which we are able to judge of the presence of a force. Any acceleration which a moving body suffers, whether that acceleration be change of direction or change of rate of motion or change of both, indicates the existence of an external force; and the relation of this force to the change of motion which it produces is given with rigorous exactness in

Law II.—Change of motion is proportional to the impressed force, and takes place in the direction of the straight line in which the force acts. By quantity of motion is meant what we now call momentum, which is proportional to the mass and velocity conjointly; and by impressed force is meant impulse, which takes account not only of the intensity of the force, but also of the time during which the force acts. The impulse of a force is measured by the product of the time of action into its intensity if it is constant, or its mean intensity if it is variable. The second law may now be stated thus: The change of momentum of a body is numerically equal to the impulse which produces it, and is in the same direction. Since motion and rest are merely relative terms, we may for convenience suppose the body to be originally at rest, and measure the force by the momentum it produces in unit time. If we act upon different masses with the same force, the momenta produced must be the same; and hence the velocity generated is inversely as the mass. In this way we compare masses. If we act upon the same mass with different forces, the forces are equal to the momenta produced, i.e., are directly proportional to the velocities generated. In this way we compare forces. Further, the second law evidently implies that if a number of forces act upon a given body, each produces exactly the same effect which it would have done had the others not been present. Consequently forces are to be compounded and resolved exactly as velocities, accelerations, momenta, and indeed all vector or directed quantities are. See VECTOR. These two laws supply us with exact methods for measuring the fundamental units of time, space, and mass, and the first direct derivatives of these, velocity, force, momentum, acceleration, &c. By them we can investigate the motion of a single particle under the action of given forces; but when there are mutual actions between two or more bodies, such as attraction, repulsion, pressure, &c., more is required for a complete investigation, and this is supplied by

Law III.—To every action there is always an equal and opposite reaction; or, the mutual actions of any two bodies are always equal and oppositely directed. The mutual action between two bodies, when viewed as a whole, is called stress; and action and reaction are simply opposite aspects of the same stress. Take, for instance, a mass resting on a horizontal plane. The stress is in

this case a pressure. If we consider the plane only, the pressure we regard as acting downwards; and if we consider the mass alone the pressure acts upwards. Here we have the action of the mass upon the plane, and the reaction of the plane upon the mass; and these are equal in amount but opposite in direction. In the case of two bodies connected by a stretched string, the stress is of the nature of a tension, and the force acting upon either body is directed towards the other, and is the same in amount whichever body we consider. In cases of attraction and repulsion the same holds. The iron attracts the magnet just as the magnet attracts the iron, the changes in their respective momenta being equal and oppositely directed. In a scholium appended to this law, Newton extends the principle to quite a different order of quantities. The full meaning of this scholium was first noticed by Thomson and Tait, who thus translated it:—*If the action of an agent be measured by the product of its force into its velocity; and if similarly the reaction of the resistance be measured by the velocities of its several parts into their several forces, whether these arise from friction, cohesion, weight, or acceleration: action and reaction, in all combinations of machines, will be equal and opposite.* Here the forces of resistance against acceleration are reckoned as reactions equal and opposite to the actions which produce the acceleration; or the forces producing acceleration form with the reactions against acceleration an equilibrating set of forces. This is the statement of D'Alembert's principle, enunciated by him in 1742, and is thus an evident deduction from Newton's comments on the third law. But further, the product of a force into its velocity, i.e., into the velocity of the point on which it acts, is simply the rate at which an agent works, so that Newton's scholium contains the complete statement of the modern theory of energy. He required only to have known what became of the work lost in friction to have been himself led to the discovery and explicit enunciation of the conservation principle. See DYNAMICS, ENERGY, KINETICS.

Motion in Plants. See IRRITABILITY, SPORE, MOVING PLANT.

Motive, the leading theme in a piece of music. A short musical subject.

Motley, John Lothrop, a distinguished American historian and diplomatist, was born at Dorchester, Massachusetts, April 15, 1814, and educated at Harvard University and in Germany. His first literary efforts were in the direction of historical romance, but neither *Morton's Hope* (1839) nor *Merry Mount* (1849) was successful. Meanwhile he had been slowly developing, in certain critical essays, a power of grasping and appreciating historic events; and in 1849 he went to Europe to collect materials for a record of the great struggle of the Dutch against the power of Spain. After five years' industrious research in Holland and Germany, he published in 1856 *The Rise of the Dutch Republic*, a work not only of solid and accurate study, but of enthralling interest, marked by impassioned advocacy of civil and religious liberty, sympathy with an oppressed and struggling people, and enthusiasm for the Reformation. *The History of the United Netherlands* (1860-65) continued the narrative to the time of the Synod of Dort. Mr. Motley was Ambassador at Vienna 1861-67, and at London 1869-70. After a visit to America, he finally took up his residence in England in Nov. 1872. He published in 1874 *The Life and Death of John of Barneveldt, with a view of the Primary Causes and Movements of the Thirty Years' War*; and he was engaged on a history of that gigantic conflict when he died at Kingston, Russel House, Dorsetshire, May 29, 1877.

Mot-mot, a name given to various *Fisvinigral* (*Insectores*) birds, from their peculiar cry. They inhabit tropical America and the adjacent regions. The beak is large, and has serrated edges; the tongue is provided with a number of filaments; the tail is wedge-shaped, and the two central feathers are prominent, long, and bare in the shafts for some distance from their tips. The general size is that of a magpie, and the plumage is brilliant. The Brazilian M.-M. (*Alomotus Braziliensis*) is green above, the top of the head being black. The under parts are green with a crimson lustre, and there is a black spot on the breast. The M.-M. feeds on insects, and like the swallow, &c. captures its prey on the wing.

Motor Nerve. See NERVE AIR.

Motril', a town of Spain, province of Granada, 32 miles S. of the city of Granada, and about 3 miles from the Mediterranean shore. The rising ground behind is covered with vinerias, and the inhabitants are engaged in agriculture or fishing. Pop. 12,850.

Mott'oes (Ital. *molto*, 'a word,' from Lat. *mutire*), in Heraldry, are words or sentences accompanying a badge or coat of arms, and usually inserted in a scroll. They may be punning, as that of the Holdens, *Teneo quia teneor* ('I hold because I am holden'); *Tost on tard vienne*, of the house of Vienne; or *A tout venant beau jeu*, of the Sires de Beaujeu: veritable rebuses, as *M qui T'M* ('aime qui t'aime') of the Kerkos family in Brittany: war-cries, as the ancient *Dieu et mon droit*, first assumed by Henry VI.: moral or religious sentiments, as *Etiam si omnes ego non* ('though all, yet not I'); *Per ardua virtus*, &c.; or they may enshrine some historic fact, as the *Grip fast* of the Earls of Rothes, alluding to the rescue from drowning of Queen Margaret by Bartholomew Leslie.

Mouflon, the name usually given to certain species of Sheep (q.v.) of large size, such as the Argali (q.v.) (*Caprovius argali*) of Siberia, the Bighorn or Rocky Mountain sheep of California, and the Aoudad (*Ammotragus Tragelaphus*) of N. Africa. The *Caprovius musimon* of Corsica, Sardinia, &c., is also called the M. or 'Musimon.' It attains the size of a small deer, and is brown above and white below. The horns are very large.

Mould, or **Moul'diness**, a name popularly given to the flocculent and thread-like *Fungi* which prey upon provisions, and a variety of other articles of daily use, as also on decomposing organic bodies. Two families of fungi are represented by the common moulds; and we may take as characteristic examples of these the *Mucor mucedo* among the *Physomyces*, and *Aspergillus glaucus*, or 'blue M.', and *Penicillium crustaceum*, among the *Hyphomycetes*. In the latter the whole fungus, both the concealed part or *mycelium*, and that portion which is exposed to the atmosphere, the *aerial hyphæ*, consist of cells varying only in size and form. The only reproductive bodies are *conidia*—that is, ordinary cells of a spherical form produced at the ends of the aerial hyphæ and detached in succession. They are true spores. In *Mucor* the spores, instead of being naked exposed cells, are produced within special bodies known as *sporangia* or *asci*,—roundish heads borne at the extremity of thread-like stalks, which rise vertically from the hyphæ. The spores of M. have the property of retaining their vitality for a long period when dried, and from their extreme lightness are in this form disseminated with the greatest facility through the air. On reaching a nutrient substratum they germinate. Many of the moulds are capable of sustaining life when immersed in fluids, and Berkeley tells us that from their inherent power of appropriating what is nutritious and rejecting what is hurtful, they are often developed in solutions of poisonous metallic salts, which would be fatal to fungi in general. They are among the most destructive agents in the propagation of disease, and are a fruitful source of cutaneous disorders in man. Their agency in fermentation will be mentioned under article YEAST. Of the three species above mentioned, the first-named is extremely common on fruit, and is not destroyed in the process of preserve-making; the second occurs very commonly on a variety of decaying substances—as lard, bread, cheese; and the third is found on all sorts of decaying bodies. In the case of apples, pears, and other fruit becoming rotten, it is the work of one or more moulds (e.g., *Mucor stolonifer* and *Botrytis cinerea*), that have obtained admission through a bruise or other defect in the skin of the fruit, and feed upon the cell-sap that escapes into the intercellular spaces. There are a number of other common species of moulds; and it may be remarked that the whole of the group form beautiful objects when viewed under the microscope. See MILDEW and VINEGAR PLANT.

Moul'dings are ornamental forms applied to edges or angles of masonry and joiner-work. Eight regular mouldings are recognised in Grecian and Roman architecture, and each individual member occupies the position it is adapted for, where its own graceful form is best displayed, while it contributes to the production of a beautiful and rich design. Grecian M. differ from Roman in being parts of conic sections, as the ellipse and hyperbola, the Roman forms consisting of arcs of circles, which may be described with compasses as shown in the cut. 1. The

cyma or *cyma recta* is used as a finishing and covering member. 2. The *cyma reversa*, *ogee*, or *talon*; and 3. The *ovolo*, *echinus*, or *quarter-round*, properly forms a support for other mouldings. 4. The *cavetto* or *hollow* finds its proper position as a crowning moulding. 5. The *torus*, or *half-round*, significant of strength, is found at the tops and bottoms of columns. 6. The *scotia* or *trochilos*, owing to its form, is usually placed in bases, and is effective in separating other members. 7. The *astragal* or *bead* is merely a small torus, and like it is used to bind parts together. 8. The *fillet* is introduced between curved M., and is often used as the crowning member of a cornice. All M. in classical buildings, except the *cavetto* and *scotia*, usually bear sculptured enrichments. Gothic M. consist of rounds, deep hollows, and right lines, which, though apparently arranged in hap-hazard fashion, produce a great variety of design.

Moulding.

Moulins, a town of Central France, department of Allier, on the right bank of the river Allier (here crossed by a fine stone bridge of thirteen arches and 985 feet long), and 213½ miles S.S.E. of Paris by rail. The houses are almost all built of brick. M. has a fine Gothic cathedral (still unfinished), a museum, a theatre, and a library of 12,000 volumes. A square tower, which was part of the old castle of the Bourbons, is now used as a prison. M. manufactures cutlery, leather, ropes, textiles, and hosiery, and has great trade in agricultural produce. It derives its name from the numerous corn-mills (Fr. 'moulins') in its neighbourhood. Pop. (1872) 17,836.

Moulmein' (*Maulmain*), a seaport in the district of Amherst, British Burma, at the mouth of the Salween, Gyne, and Attaran rivers, about 90 miles E. of Rangoon. Pop. (1875) 63,841. It was founded in 1826, after the first Burmese war, as a military station, but has now only a few native troops. In 1874-75 the exports were valued at £927,639 (chiefly teak and rice); the imports at £909,814 (chiefly piece-goods, stores, and treasure). It has regular steam communication with Rangoon, Calcutta, and Singapore.

Moul'ting (from the same root as Fr. *muer*, Lat. *mutare*, 'to change') or **Ec'dysis** (Gr. 'a casting off'), is the throwing off, as a preliminary to the replacement, of external parts and coverings in animals. Thus birds 'moult' or 'cast' their feathers; serpents, newts, &c., shed their external skin or *Epidermis* (q.v.); crustaceans (e.g. lobsters and crabs) periodically cast their shells, and remain soft-bodied until the process of lime-deposition completes the new shell; and many insects and other Arthropoda (q.v.) in the course of their development shed their skin, especially in the larval state, many times in succession. In the insects and crustaceans the process of M. is intimately associated with the growth of the body. A crab or lobster can increase in size only when the skin is soft and after the shell has been shed, and so completely is the process of M. carried out in these animals, that even the horny inner lining of the stomach is cast off and replaced along with the 'shell.' Birds moult the feathers and acquire a new plumage, either through the production of absolutely new feathers, or by new growths being added to the existing plumage. The hair of mammalia is also periodically shed and renewed; and even hard and dense parts, if they only belong to the skin-structures, e.g., the antlers of the deer, may be annually shed and reproduced.

Mound (Fr. *monde*, Lat. *mundus*, 'the world'), in Heraldry, a representation of a globe bearing a cross pattee, probably adopted by the Emperor Justinian, as a symbol of the subjugation of the world to the Cross.

Moun'tain is the name generally given to a well-marked elevation of the earth's surface. Popularly it is distinguished from *hill* as being applicable to elevations of greater dimensions; geologically, however, no line of distinction can be drawn between the two. Mountains rarely occur singly; they are generally in groups or systems. The most usual form which these groups assume is the chain, typical examples of which are found in the Rocky Mountains, Andes, and Alleghanies of America, the Apennines, Pyrenees, Carpathians, Urals, Caucasus, Himalayas, Thian-shan, &c., of Europe and Asia, and the Atlas, Kong, and various coast ranges of Africa. There is no case of an extensive M. chain rising abruptly from a plain. It either forms on its one aspect an extended gradually sloping surface, or bounds an elevated plateau or table-land. Thus the Andes of S. America, whose western base is washed by the waves of the Pacific, gradually falls off on the E., forming the watershed of the Orinoco, Amazon, and La Plata. On the other hand, the Himalayas, whose southern slopes feed the tributaries of the Ganges and Indus, look northwards over the fertile plain of Thibet towards the great central plateau of Asia. An attempt to estimate the real breadth of M. chains is therefore as futile as useless. The vertical contour of a chain is exceedingly irregular, rising in various points into *peaks*, which are separated from each other by cols, valleys, or gorges. Frequently a chain consists of several parallel ridges, a configuration which characterises the Rocky Mountains, Andes, and especially the Alleghanies. The most lofty peaks of our globe occur among the Himalayas and the Andes of Peru, and this suggests the only sure generalisation which can be made in reference to the distribution of mountains, namely, that the highest land is found at or near the equator. The Alps of Europe, it is true, lie without the torrid zone, but there are very few cases of lofty summits in higher latitudes than the temperate zone. Siberia, Russia, and Labrador are singularly devoid of M. chains; and though the surface of Greenland appears to be much more diversified, the elevations are comparatively moderate. The influence which mountains exert upon climate is well-marked all over the world. They form the great watersheds, and determine the course of streams and rivers, thus indirectly influencing the internal commerce of a country. If sufficiently high they act also as a 'shed' to the clouds; so that that side which looks in the direction from which the moist winds come has in certain circumstances a totally different climate from localities distant only a few miles, but which are exposed to dry winds. Similarly, mountains in many cases afford protection from injurious winds. To this cause chiefly is due the suitability of many of the southern European towns as resorts for invalids during winter.

The formation of mountains is the result of hypogene or subterranean action; or, as in Scandinavia and the W. Highlands of Scotland, of surface denudation. By some the name M. is restricted to the former class; and the tendency of such ranges to form chains indicates that the primary systems at least have been the result of the wrinkling of the earth's surface due to cooling and contraction. According to Elie de Beaumont, they tend to form parts of great circles—these being the lines of least resistance, and therefore the lines along which rupture would take place. In volcanic action and earthquakes, we have the production of mountains on a small scale; and no doubt the same agencies were at work in past ages, and produced the present configuration. It is possible in many cases by a study of the distortion of contiguous strata, to fix the geological age of our mountains—or at least the age of the last great upheaval, for there is no reason to suppose that mountains have been the result of one intense eruption; opinion rather inclines to regard them as the final result of a succession of upheavals, which need not have been more violent than the present gradual rise of Scandinavia. Many ranges date probably from Miocene times, when volcanic action seems to have attained its maximum. Where the crust has once yielded to a ruptive stress there it will probably yield again; and hence the reason why earthquakes occur in certain definite localities, and are hardly known in others. The dynamics of M. formation are still little understood. The researches of Hopkins and Thomson, however, into the phenomena of stresses and tensions have explained some of the most fundamental characteristics of M. configuration.

Moun'tain Ash. See ROWAN.

Moun'tain or Carboniferous Lime'stone. See LIME-STONE.

Mountmell'ick (Irish Gael. *Montiaghmeelick*, 'the boggy ground'), a market-town of Ireland, in Queen's County, on the Owenass, a tributary of the Barrow, 6 miles S.W. of Portarlington. A Quaker colony, it has thriving manufactures of tweeds and friezes, besides breweries, tanneries, potteries, &c. Pop. (1871) 3316.

Mourne Mountains, a range in Ireland, county Down, separating the basins of the Newry and Lagan, and rising in Slieve Donard to a height of 2796 feet, and in Mount Eagle to 2084 feet. They are named from a certain *Mughdhorn* (Mourne), some of whose descendants settled here in the 12th c., but the original name of the mountains was *Beanna-Boirche* ('Boirche's Peaks').

Mouse (*Mus*), a genus of *Rodentia* (q. v.) included in the family *Muride* (q. v.) which also comprises the Rat (q. v.), Vole (q. v.), &c. It is represented by the Common M. (*M. musculus*), which is too well known to need any detailed description. This little creature is most prolific, and also presents variations of marked kind in colour and size. White mice are not uncommon, and piebald varieties are frequently produced. The usual colour is a greyish-brown, which in summer becomes darker. The harvest M. (*Mus messorius* or *Micromys minutus*) is also a well-known form, attaining a length of 5 inches, inclusive of the tail. Its colour is reddish-brown above and white below. The nest is constructed in a most ingenious manner on the stalks of grasses, and is formed of dried grass and fragments of like material. The ears of the harvest M. are shorter than those of the common M., and its head is of narrower proportions. The Barbary M. (*Mus barbarus* or *Gelunda Barbara*) is of a brown colour, and is marked by longitudinal stripes of orange yellow above, the under parts being white. The field M. is now regarded as belonging to a different genus from the ordinary M. The length of the short-tailed field M. is 5 inches, including the tail, and the colour is brown above and grey below. It is sometimes named the field vole, and appears occasionally (as in the S. of Scotland in 1876) in immense hordes, which commit great havoc among the crops. The long-tailed field M. is another species, also known as the bank vole or campagnol. The white-footed M. (*M. leucopus*) of America, and the *M. punulus* of S. Europe are species allied to the common M.

Mouse-Ear Chickweed is the name given to a genus of *Caryophyllaceæ*, botanically called *Cerastium*, from some of the commonest species having a superficial resemblance to chickweed, but possessing soft oval leaves. There are in all about forty species, inhabitants of all temperate and cold regions. In Britain four are common, another (*C. arvense*) is not rare, and other three are confined to Alpine districts of the kingdom, one of them (*C. trigynum*) being limited to the borders of the Alpine and sub-Alpine rills and springs of the Scotch Highlands.

Mouth, the anterior aperture of the alimentary canal in animals. It may be surrounded by tentacles (as in Zoophytes and Polyzoa) and may have horny jaws or teeth (leech, cuttle-fishes, &c.), while in insects, crustaceans, &c., the jaws are modified limbs. The jaws of vertebrate animals, on the other hand, are invariably parts of the head. The M. in higher animals is bounded by the *lips*, and is usually provided with teeth. The hinder part of the M. is called the *pharynx*. The openings or apertures of the M. include the external opening, the apertures of the hinder nostrils, the œsophageal opening, or that of the gullet, and the openings of the Eustachian tubes. See EAR.

Malformations of the M. The most common of all the congenital deformities is *harelip*, which may be simple, double, or complicated. In *simple* harelip there is a cleft through the upper lip, on one side of the middle line, but no other deformity. The cleft is usually on the left side, and it generally extends from the nostril to the free edge of the lip. In *double* harelip there is a median tubercle, bounded on either side by clefts, one of which commonly reaches into the nostril, while the other does not. The incisive bone, which corresponds to the median tubercle, has generally four teeth, but their number varies. Harelip, either single or double, may be complicated with fissure of the palate, and in cases of double harelip the incisive bone often projects and appears to hang on to the end of the nose. Fissured palate is a malformation which often co-exists with hare-

lip, but also very often without it. There may be simple fissure of the soft palate, fissure of the soft and part of the hard palate, and complicated cleft, which generally extends through the whole mouth, from the red edge of the lip in front to the uvula behind. These deformities may all be either entirely removed or much improved by surgical operations, and as a general rule the operation should be performed during infancy or childhood.

Diseases of the M. are similar to those which occur in other parts of the body covered with mucous membrane, modified, however, by peculiarities of situation and exposure. The most common are the various forms of *Stomatitis* (q. v.), viz., simple erythema, diphtheritic exudation or eruption, and inflammation of the follicles of the mucous membrane. Ulcerative and gangrenous inflammation, usually called *Noma* in the returns of the Registrar-General, is described under *Cancrum Oris* (q. v.). The tongue is liable to acute inflammation, or Glossitis (q. v.), and to various forms of ulceration, as simple ulcers, mercurial ulcers, syphilitic ulcers, and other syphilitic lesions; and it may also be the seat of tumours and cancer. Inflammation of the tonsils, or *Tonsillitis* (q. v.) is a very common affection, and may exist in different degrees of intensity, as *angina mitior*, and *angina gravior*. See articles APHTHÆ; GUMS, DISEASES OF; THROAT, DISEASES OF; and TONGUE, DISEASES OF.

Moveable, a term of Scotch law equivalent to *Personal* in the law of England. See HERITABLE AND MOVEABLE; HEIR.

Movement, a continuous number of musical ideas forming a connected whole. A sonata or symphony is usually divided into several movements, which may take the form either of 'Movements of Development,' or 'Movements of Episode.'

Moving Plant (*Desmodium gyrans*), a leguminous plant, a native of the E. Indies, has received the above name from the constant motion of its leaflets. The leaves commonly consist of three leaflets, and the two small lateral ones are continuously on the move, rising to meet each other, and then retreating in a series of jerks. In a large plant the appearance is most curious, and has been compared to the working of a number of railway telegraph signals—hence the name 'telegraph plant' sometimes applied. The process goes on in a greater or less degree both during day and night, but is most vigorous in warm moist weather. The larger terminal leaflet also very gradually oscillates from the one side to the other, and through a horizontal to a depressed position. These movements (of which *D. gyrans* and *D. vespertilionis* also partake) have been referred to various causes; the determination still remains *sub judice*. It is not influenced by mechanical irritation as in the sensitive plant. The *M. P.* is often grown in hothouses, as are also other handsome species of the genus. Altogether it numbers about 140 species, chiefly Indian and tropical, African and American.

Mow (*Mau*), the principal town in the district of Jhansi, N.W. Provinces, British India, 205 miles W. of Allahabad. Pop. (1872) 16,428. It is a well-built town with many temples, and conducts an extensive trade. Exports, £140,000; imports, £110,000. The staple manufacture is coarse and fine cotton cloths, both white and dyed, which are sent to all parts of India. It is to be carefully distinguished from Mhow (q. v.).

Moxa is a peculiar form of counter-irritation, introduced into Europe by the Portuguese, who acquired it from the East. As practised by the Chinese, a small cone is formed of the downy covering of the leaves of *Artemisia Moxa*, or of the pith of such plants as the common sunflower, or of linen steeped in nitre. The cone is placed over the affected part, and set fire to. In this country issues were established by means of the *M.* as follows:—A piece of lighted German tinder was placed on a frame, and the flame directed on to the skin by means of a blow-pipe. The same end may be attained by means of the actual cautery, which is now occasionally used in certain forms of neuralgia, and in chronic diseases of the joints.

Mozambique, a region on the S.E. coast of Africa, nominally belonging to Portugal, whose authority, however, is practically confined to a few settlements. The coast-line of *M.* extends from Cape Delgado in 10°41' S. lat. to Delagoa Bay in 26°30' S. lat., a distance of 1200 miles. The inland boundary is undefined, but the area of the province is officially estimated at about 400,000 sq. miles, and the pop. at 300,000. Portuguese rule extends 400 miles up the Zambeze to the confluence of the

Loangwa, and up the Shire for 130 miles, but elsewhere it ceases within 100 miles of the coast. The Limpopo, the only other considerable river that flows to the sea through *M.*, is only navigable for 60 miles. *M.* is divided into two nearly equal parts by the river Zambeze, and the southern portion is known by the name of Sofala. The climate of *M.* is very hot and humid, and consequently unhealthy. The soil is rich, and under an efficient government the country is capable of producing large quantities of rice, coffee, cotton, sugar, and tobacco. It also possesses large but undeveloped resources in the shape of wax, gums, spices, and valuable woods. Ivory to the value of £50,346 was exported from the port of *M.* in 1875. Coal is found near the Zambeze, as well as iron of superior quality. Gold and silver are likewise to be obtained, and the deposits of both were once extensively worked. The principal ports are *M.*, Delagoa Bay, Ibo, Quilimane, Inhambane, and Lourenço Marques, whose aggregate imports and exports in 1875 amounted to £174,282 and £202,412 respectively. Trade is carried on chiefly with India and Marseille, but is paralysed by the existence of slavery outside of the circle of Portuguese authority, and by the inertness of the government. Delagoa Bay, the only first-class harbour between Natal and Zanzibar, is the nearest place of export for the produce of the Transvaal gold-diggings, Myack Island, the last of the low-lying cluster that fringes Delagoa Bay, has in recent years proved an excellent sanitarium for fever-stricken Europeans.—*M.*, the capital, is situated on an inshore coral island, 3 miles from the mainland. It possesses a good harbour, is fortified, and contains an arsenal which was completed in 1876. In 1875, 224 vessels of an aggregate tonnage of 32,000 tons, entered the port of *M.* Pop. 8522.

Mozambique Chann'el divides Madagascar from Africa. It has a length of about 1000 miles, with an average breadth of 450 miles. The Comoro Islands (q. v.) are in the *M. C.*, near its northern extremity.

Mozarabic Liturgy (Ar. *mostarab*, 'one who has adopted the Arab mode of life,' applied to Christians and Jews in Africa and Spain who did so to avoid persecution), is the most perfect extant form of the ancient Gallican and still older Ephesine Liturgy (see LITURGY). Its early history is unknown, but the groundwork is of the highest antiquity. It was suppressed in Aragon in 1060, and in Navarre, Castile, and Leon in 1074, that the Roman Use might be established; but revived in the beginning of the 16th c. by Cardinal Ximenes, who endowed a chantry at Toledo for its peculiar use, where it has been preserved to the present time. Blunt's *Dict. of Doct. and Hist. Theol.* (1872).

Mozart, Wolfgang Amadeus, one of the greatest of musicians, was born at Salzburg, in Austria, January 27, 1756. He could play the harpsichord well at four years of age and composed before he was six. His father, a musician, guided his efforts, and from 1762 to 1765 exhibited his precocious talents as performer and composer to the courts and wealthy circles of many European cities, including Vienna, Paris, and London. Four *sonatas* were *M.*'s first published work (Par. 1764). In 1768 he was made Concert-meister by the Archbishop of Salzburg, but received no salary till 1772. His visit to Italy (1769-71) was a succession of triumphs in Milan, Bologna, Naples, and Rome; among the Italian operas written there, *Mitridate* (Milan, December 1770), the work of a boy of fourteen, had twenty successive representations. After some years' activity spent in composition at Salzburg, he left that town (September 1777) to seek a wider field of activity; but, failing in various places to obtain anything but empty applause, he returned to Salzburg as cathedral organist (January 1779). From March 1781 till his death, December 5, 1791, he lived at Vienna, seldom free from the anxieties of poverty. He was made 'chamber musician' in 1787, and in 1790 had a pension of 1000 florins granted him by some musical noblemen. Among *M.*'s works we may name the operas *Idomeneo* (1781); *Le Nozze di Figaro* (1786); *Il Don Giovanni* (first performed October 29, 1787, at Prague); *Così fan Tutte* (1790); *Die Zauberflöte* ('magic flute,' 1791); and *La Clemenza di Tito*; the great series of *Symphonies*; the string quartets, pianoforte sonatas, and other chamber music; the concertos for piano and orchestra, increasingly appreciated of late years; and the church compositions, including *Masses* and the *Requiem*. He wrote in all 800 separate works,

including 16 operas and 33 symphonies. M. not only possessed a rich, triumphant, and (musically speaking) universal genius, but profound learning and untiring industry. As an instrumental composer he has been surpassed only by Beethoven, while in opera he has no equal. He was of a generous and lovable disposition. There are lives of M. in German by Niemischek (1798), Nissen (1828), Otto Jahn (4 vols. Leips. 1856-59; new ed. 2 vols. 1869), and Nohl (2d ed. 1870; Eng. trans. by Lady Wallace, 2 vols. 1877). In English there are Holmes's *Life of M.* (1845); and Lady Wallace's translation of *M.'s Letters* (1865).

Mozufferpore (*Mizaffarpur* = town of Muzaffar), the chief town of the district of the same name in Bengal, British India, on the little Gunduck river, 50 miles N.E. of Patna. Pop. (1872) 38,223. It is the home of the Behar Scientific Society, an association of Mohammedans.—The district of M., which up to 1875 constituted the western portion of the old district of Tirhut, has an area of 2969 sq. miles; pop. (1872) 2,188,382. It is highly cultivated, the principal crops being rice, barley, pulses, indigo, and tobacco. Saltpetre is also largely produced. The other towns are Hajipur, Sitamarice, and Lalgunge. In the year 1876-77 the exports were valued at £800,000, chiefly indigo, tobacco, saltpetre, oil seeds, and hides; the imports at £680,000, chiefly piece-goods, food grains, salt, cattle, and indigo seed. There is considerable traffic with Nepal.

Mozuffurnuggur (*Mizaffarnagar* = city of Muzaffar), the chief town of the district of the same name, in the N.W. Provinces, British India, 984 miles N.W. of Calcutta. Pop. (1872) 10,793. It was founded about 1633, and is closely built. It is now a railway station. Malarious fever is said to have been caused by the proximity of the canal.—The district of M., which lies in the *doab* between the Ganges and Jumna rivers N. of Meerut, has an area of 1659 sq. miles; pop. (1872) 690,107. It is also watered by the Hindun, and by the Ganges and E. Jumna Canals. Both the fertility and health of the country have suffered from an excessive water supply. The crops are wheat and barley, rice, sugar-cane, and millets; about 80,000 tons of food grains are annually exported. The towns, besides M. itself, are Kairana, Shamli, and Jelalabad. During the Mutiny of 1857 there were some murders and much plundering.

Mtzensk, a town in Russia, government of Orel, on the Zusha, 78 miles S.W. of Tula by rail, has thirteen churches, and important trade in brandy and agricultural produce. Pop. (1870) 14,159.

Mualitch, a town of Asiatic Turkey, in the vilayet of Brussa, 16 miles S. of the Sea of Marmora, and 42 W. of the town of Brussa. It has considerable trade with Constantinople in wool, silk, and fruit. Pop. about 16,000.

Mucilage (from Lat. *mucus*, 'slime') is a vegetable exudation allied to gum, but which mixed with water swells up and softens without dissolving. The term is also applied in pharmacy, &c., to any thick aqueous solution of gummy matter. The so-called gum-tragacanth is an example of a mucilaginous substance. It, in the form of M., is used in medicine as a demulcent for making pills to a proper consistency and for suspending heavy powders in liquids.

Muckers (Prov. Ger. 'hypocrites'), a mystic sect founded at Königsberg in the early part of the present century by Ebel and Diestel, two German pastors who had adopted the theosophical views of Johann Heinrich Schönher (born at Memel, 1771; died at Königsberg, 1826). Charges of immorality preferred against the members of this sect—many of them persons of wealth and station—led to a process (1835), which terminated (1842) in the deposition of both ministers, and in the imprisonment of Diestel. How far these accusations were based on fact has been warmly contested, Graf Kanitz in his *Aufklärung über den Religionsprozess* (Basel, 1862) maintaining that the judges were biased and unfair; while Hepworth Dixon (*Spiritual Wives*, 1868) sees in the M. the German counterpart of the English Agapemone, and the American Perfectionists.

Mucous Membrane and **Mucus**. M. M. is the name given to the delicate membrane which lines the interior of the passages of the bodies of higher animals. Like serous membrane, it consists of three chief parts—(1) a primary membrane of structureless nature, often named the basement membrane; (2) a

layer of secreting cells; and (3) a network capillary of blood-vessels. The latter furnish the blood from which the cells secrete the mucus or special product of M. M. This variety of membrane is soft and vascular, and is usually attached to other structures and tissues. That covering the tongue is attached to muscles; that lining the intestine to a lower or submucous layer, which in turn rests on the intestinal muscular fibres; and that of the tympanum or 'drum' of the ear to *Periosteum* (q. v.). The epithelial cells of M. M. present considerable variations in form and structure, and the basement-membrane on which the cells rest is structureless and transparent. The entire digestive system is lined by M. M., which is modified in certain regions to form granular or secreting structures. Beginning with the mouth, we find this membrane lining that cavity, and continued downwards into the gullet and stomach. Thence it proceeds along the intestine to the anus. It is also continued from the digestive tract into such openings as the ducts of the liver, sweetbread, and gall-bladder. The respiratory or breathing organs are similarly lined with M. M. The cavity of the nostrils is lined by a specially modified M. M., known as the Schneiderian membrane, in which the olfactory nerves ramify. The eyelids and conjunctiva are provided with this structure, and also the lachrymal sac and canal (see EYE). It is found investing the windpipe, and extends into the lungs. The internal genital passages are lined with M. M., and the urinary organs have a similar investment. But as is well seen in the gastric glands of the stomach, or in the intestinal glands, the M. M. is convoluted or folded to form glands of various kinds, the secretions of which have most important functions in the economy of the body. Mucus is found in the fluids which come in contact with, or which are secreted by M. M. Thus the saliva of the mouth contains mucus which is secreted by the M. M. lining the mouth. Mucus when microscopically examined is seen to contain a large number of epithelial cells, which have become detached from the surface of the membrane, and which float in a colourless and somewhat viscid fluid. It is distinguished by containing a peculiar substance known as mucin, and differs from albumen in that it does not contain sulphur. The function of mucus is that of lubricating the surfaces on which it occurs, although it probably possesses other functions of a more complicated nature, but which are still undetermined.

Mudâr (the Hindustani and Bengali name for *Caleopsis gigantea*), one of a small genus of Asclepiads, is a branching shrub or small tree, bears ovate leaves about six inches long, and deep rose, somewhat bell-shaped flowers. The inner bark of the young branches furnishes a valuable fibre, equal in strength to hemp, and all parts of the plant abound in an acrid milky juice, that on hardening resembles gutta percha. In a fresh state, it is said to be very efficient in cutaneous diseases, while the powder of the bark of the root is an excellent substitute for ipecacuanha in the treatment of dysentery. In large doses it is a reliable cholagogue, and is also a sedative to the muscular fibres of the intestines. A smaller species (*C. procera*), growing also in India, and ranging to Syria and various parts of Africa, possesses similar qualities. M., in combination with arsenic and black pepper, forms the celebrated 'Asiatic Pills.' The active principle, called *mudarine*, gelatinises on the application of heat, returning to its fluid state when cold.

Mudfish. See DIPNOI and LEPIDOSIREN.

Mudie, Robert, was the son of a weaver, and was born in the neighbourhood of Dundee, Scotland, 28th June 1777. After holding the appointment of drawing master in the Inverness Academy and Dundee High School, he removed to London in 1820, and became a reporter on the *Morning Chronicle*. Worn out by a life of incessant literary toil, M. died 29th April 1842. In the course of twenty years he produced more than eighty volumes, only one of which still possesses any vital interest. The *Feathered Tribes of Great Britain* (2 vols. 1833), though desultory and incomplete, ranks as a British classic in natural history.

Mudie's, the largest circulating library in London, and probably in the world, was established in 1842 by Mr. Charles Edward Mudie, who is still manager and a principal shareholder of the concern, although it passed in 1864 into the hands of a limited liability company. The library is situated in New Oxford Street, near the British Museum, and has a branch in the

City, and another at Manchester. There are various classes of subscriptions. £1. is a year entitles a town member to choose one volume from the entire library, and to exchange it daily; £2. 2s. three volumes in the same way; £3. 3s. six volumes; and every additional guinea, two volumes extra. Country subscribers obtain sets of books at reduced rates. There are lower subscriptions (from 10s. 6d. upwards) for the unreserved portion of the library. Many provincial libraries and institutions obtain their books from M., some paying as much as £500 a year. Several thousand copies of a popular work are frequently purchased for the library. Since its commencement, Mudie's has issued 3,000,000 volumes to its subscribers; the daily exchange of books is about 12,000; and over 500,000 volumes are at present available for circulation. A large staff of officials is employed, and all the binding work is done at the premises in Oxford Street.

Mûd'ki (*Moodkee*), a town in the district of Ferozpore, Punjab, British India, 26 miles S. of the left bank of the Sutlej, and 65 S.E. from Lahore. It is celebrated for the battle of 18th December 1845, which opened the first Sikh war. Lord Gough, after a fierce struggle, finally drove the Sikhs across the Sutlej.

Muezz'in (from Arab. *uzn*, 'an ear'), a Mohammedan official, partly answering to the medieval watchman. Bells not being allowed in mosques, the M. summons the Faithful to prayer (*namas*) five times in the twenty-four hours, his chant by day being termed the *adan*, by night the *ita*. That he may not from his lofty minaret be able to spy into the privacy of the surrounding harems, a blind man is usually chosen for the post.

Muf'ti (Arab. 'expounder'), in Turkey, an interpreter of the Koran. The Grand M. or *Sheik-ul-Islam* ('head of the elect') presides over the Ulema (q. v.), and ranks next to the Grand Vizier, like whom he holds his appointment immediately from the Sultan. Though nominally a spiritual authority, he performs no priestly functions; but war cannot be proclaimed, or peace concluded, without the decree (*fatwa*) of the Grand M. and his Ulema, 'that it is conformable to law.' The title M. is also bestowed on the jurisconsults attached to local and general councils throughout the dominions of the Porte.

Muggleto'nians were a sect which arose in the end of the 17th c., founded by Ludovic Muggleton (1609-97), a tailor in London, and an associate named Reeves. These two professed to be the two witnesses of Rev. xi. 3-6, Reeves representing Moses, and Muggleton Aaron. They affirmed that they had received special revelations from heaven, as well as power to destroy all who opposed them. Some of their other strange notions were that Satan became incarnate in Eve, that it was God the Father who died on the cross, having left Elijah to rule in heaven during his absence on earth, &c. The sect survived till within the last few years. See *The Snake in the Grass* (1698). The last edition of Muggleton's works appeared in 1832 in 3 vols.

Mühl'berg, a town in Prussia, province of Saxony, on the right bank of the Elbe, 83 miles S.E. of Magdeburg, with two churches and a castle, and is famous for the scene (24th April 1547) of the Emperor Karl V.'s victory in the Schmalkaldic War over Johann Friedrich, Elector of Saxony, who was taken prisoner in the battle. Pop. (1875) 3244.

Mühlhausen, or **Mülhausen** (Fr. *Mulhouse*), a town of Elsass, in the S.W. of Germany, 30 miles N.N.W. of Basel by rail. The old town, on an island between the Ill and the Rhine and Rhine Canal, is irregular, but the newer parts are regularly built, and contain many fine buildings. The most noteworthy are the Hôtel-de-Ville (1551), the old Reformed Church, and the Synagogue. The Place de la Bourse is an imitation of the Rue de Rivoli at Paris. M. has 17 muslin and cotton, and 11 cloth manufactories, and 15 calico printworks. Morocco leather, silks, locomotives, and machinery are manufactured, and wool and cotton spinning, bleaching, and dyeing are actively carried on. Pop. (1875) 58,513 (with the suburb Dornach, 62,627). M. was made a free city of the Empire by Rudolf of Hapsburg in 1273, and was only incorporated with France as late as 1798. With the rest of Elsass it reverted to Germany in 1871.—**M. in Thuringen**, a town in Prussia, province of Saxony, on the Unstrut, 23 miles N.N.W. of Gotha by rail. It is a very old town, with a fine Gothic Marienkirche and thirteen other churches. The trade in corn and wool is considerable, and there are extensive industries in spinning and weaving wool. There

are 50 tanneries, 14 glue factories, and 14 dyeworks. Pop. (1875) 20,938.

Mühlheim am Rhein, a town of Rhenish Prussia, on the right bank of the Rhine, 2½ miles N.N.E. of Deutz by rail. It actively carries on river-traffic and commission trade, and has considerable manufactures of silks, leather, paper, oil, and flour. Pop. (1875) 17,350.—**M. an der Ruhr**, also in Rhenish Prussia, is 5½ W.N.W. of Essen by rail. It has extensive trade in sandstone and Ruhr coal (the latter amounting to about 5,000,000 tons annually), and important manufactures of iron, zinc, machinery, leather, cotton, paper, and farm implements. Pop. (1875) 15,286.

Muir, John, belongs to an Ayrshire family, traceable as far back as the middle of the 17th c. He was born at Glasgow, in 1810, studied two years at Glasgow University, thence proceeded to the East India College, Haileybury, and in 1828 went out to Bengal as a writer in the East India Company's Civil Service. After filling various offices in the revenue and judicial departments, he retired from service in 1853. In the early period of his Indian career he began to study Sanskrit, and subsequently during his residence in the East composed several religious tracts in Sanskrit verse. Since his return to his native country, M. has published a work which has given him a distinguished place among Sanskrit scholars. It is entitled *Original Sanskrit Texts on the Origin and History of the People of India, their Religion and Institutions, Collected, Translated, and Illustrated* (5 vols. Lond. 1858-70). Each volume takes up a separate subject, and has, so to speak, an independent value. Vol. I. contains the 'Mythical and Legendary Accounts of Caste;' Vol. II. discusses the 'Trans-Himalayan Origin of the Hindus;' Vol. III. is devoted to 'The Vedas: Opinions of Indian Authors on their Origin, Inspiration, and Authority;' Vol. IV. gives a 'Comparison of the Vedic with the later Representations of the principal Indian Deities;' Vol. V. consists of 'Contributions to a Knowledge of the Cosmogony, Mythology, &c., of the Indians in the Vedic Age.' M. is not only a scholar himself, but has signalled himself by his liberal benefactions to the cause of learning. Of these, the most important is the foundation (1862) of a professorship of Sanskrit and Comparative Philology in the University of Edinburgh. But Sanskrit literature is not the limit of M.'s sympathies. He has deeply interested himself in biblical questions. In 1861 he published anonymously a *Brief Examination of the Prevalent Opinions on the Inspiration of the Old and New Testaments*, with an Introduction by the Rev. H. B. Wilson. More recently, he has contributed to introduce into Great Britain a knowledge of the writings of the modern Dutch school of theological science, represented by Kuenen (q. v.), Oort, &c. In 1876 he was appointed one of the commission charged to inquire into the condition of the Scottish universities. M. is a D.C.L. of Oxford, an LL.D. of Edinburgh, a Ph.D. of Bonn, and is a member of various foreign societies.—**Sir William M.**, LL.D., younger brother of the preceding, was born at Glasgow in 1819, educated at the Grammar School of Kilmarnock, at the Universities of Edinburgh and Glasgow, and at the East India Company's College, Haileybury, went out to India in the Bengal Civil Service in 1837, served in the N. W. Provinces in various executive offices, and subsequently as Secretary to Government and Member of the Revenue Board till 1864, when he was appointed Foreign Secretary and member of the Supreme Legislative Council of India. In 1867 he became a member of the Supreme Executive Council, and was made Knight Commander of the Star of India. In 1868 he was appointed Lieutenant-Governor of the N.W. Provinces, an office which he held till 1874, when he was made Financial Minister of India. On retiring from India, he was appointed a member of the Council of India. Besides contributing a variety of articles to the *Calcutta Review*, and publishing a small work entitled *The Testimony of the Corān to the Scriptures of the Old and New Testament* (Agra, 1854; 2d ed. Allahabad, 1861), Sir William M. has written a *Life of Mahomet* (1861; new ed. 1877), a work of great learning and penetration, marked throughout by a singularly just and critical spirit. Mahomet's character is finely and truthfully conceived. The nobility of his earlier, the falsehood of his later career are admirably set forth; and if men now clearly perceive the vast difference between the 'Prophet of Mecca' and the 'Prince of Medina,' it is mainly owing to Sir William M.'s sober and discriminative history.

Muirburn, a term of Scotch law, denoting setting fire to a heath or moor. The statute of 13 Geo. III. c. 54 makes it criminal in Scotland to set fire to any heath or 'muir' between the 11th April and 1st November. The offence is punishable by fine or imprisonment.

Mukden (Mantchu, 'flourishing'), the Chinese **Shin-Yang**, or **Fung-Tien-Fu** ('rich capital'), is the chief town of Chinese Manchuria, and has been since 1631 the centre of the government of its three provinces. It lies on a tributary of the Siramuren or Liao-ho, 390 miles N.E. of Peking, is surrounded by a wall 9 miles in circuit, and contains an imperial palace (also surrounded with walls and ramparts) constructed on the pattern of that of Peking, and occupied by members of the imperial family. The trade and industry of M. are considerable. In a fine valley about 70 miles E., and near the palisade which marks the boundary of Corea, is Inden or Hing-king, formerly the family residence of the Mantchu rulers, and at the mouth of the Liao-ho, in the Gulf of Liao-tong, 110 miles S.W., is New-chang (q. v.). Pop. of M. estimated at 200,000.

Mukhtar, Ghazi Ahmed, Pasha, a Turkish general, was born about 1836. He received command of the main Turkish army operating in Montenegro in 1876, when his campaign was unsuccessful. He was appointed commander at Erzeroum in February 1877, and on the outbreak of the war with Russia obtained the supreme command in Asia. He checked the Russian invasion at Zewin in June 1877, and by an active movement thereafter relieved Kars. On 25th August he won an important victory at Kezil-Tepe. He received the title of Ghazi or Victorious from his grateful Sultan, September 1877. Near the Russian frontier in the beginning of October he withstood a furious onslaught by the Russians, which lasted several days, and cost the assailants (according to M.), 15,000 men; but on the 14th, 15th, and 16th of October, in a succession of fierce battles, M., attacked in front and flank by an overwhelming force of Russians, was disastrously defeated, his positions captured, his army cut in two—one portion surrendering and the other retreating to Erzeroum. The siege of Kars (q. v.) was in consequence vigorously renewed, and on the 18th of November, after a desperate resistance on the part of the Turks, the town was stormed by the Russians, the whole of the garrison not slain in the struggle were made prisoners, and 364 cannon captured.

Mulberry (*Morus*, from Gr. *moron*, a word of unknown origin, introduced into Greece with the tree), is a genus of milky-juiced trees or shrubs, belonging to the natural order *Moraceæ*, to which it gives name. They are represented in tropical and temperate Asia and America, but are not natives of Europe or Africa. The leaves are large and deciduous, the inconspicuous flowers in unisexual spikes, and a compound fruit is ultimately formed by the aggregation of the numerous female flowers, the calices of which become succulent—technically termed a *sorosis*. The Common or Black M. (*Morus nigra*), the best-known species, is thought to be of Persian origin. The various classical writers from Theophrastus, make frequent mention of it. In England it has been cultivated from the beginning of the 16th c. (perhaps earlier) for its highly aromatic fruit, which is used in dessert, or as a pie-erve, or for puddings and pies. From it also an agreeable wine and syrup are prepared. The M. is remarkable for its longevity, and for its vitality under adverse circumstances. The leaves are sometimes used for feeding silkworms, but the White M. (*M. alba*) is the species so largely cultivated for this special purpose. A native of China, it is supposed to have been brought into Italy about 450 years ago, where it speedily supplanted the first-named species, and is now cultivated in all countries where silkworm breeding is carried on—the latest successful attempt on a large scale having been made in California: perhaps Australia will follow. In its native country it is believed to have been grown at least 4000 years—before tea, sugar, and cotton were cultivated. The tree is of more rapid growth than *M. nigra*, and the leaves containing a larger proportion of the glutinous milky juice common to the genus, the silk from the worms fed upon them possesses a greater tenacity. Superior varieties of M. can be grafted on the ordinary stock, and of the existing species large numbers have been described under their specific names. The fruit is not sought after, and the tree is too tender for the British climate. The Red M. (*M. rubra*) of

N. America is the largest of the genus, attaining a height of 70 feet, and yielding a strong and compact timber. The Paper M. (*Broussonetia papyrifera*), a small tree, is a native of Japan and China. The 'bast' is converted into a very strong paper. It can also be used as a textile fabric, and formerly, under the name of Tapa cloth, formed the chief article of dress of the natives of the S. Pacific Islands.

Mulberry Juice, or **Mori Succus**, the deep purple juice of the ripe fruit of the *Morus nigra*, is used in medicine as a colouring matter for draughts, an agreeable addition to a gargle for sore throat, and as a refreshing drink, slightly laxative, in febrile cases. The only official preparation is the *syrup*, which may be given in doses of from 1 to 2 drachms.

Mulder, Gerardus Johannes, a Dutch chemist, was born at Utrecht, December 27, 1802, studied medicine in the university of his native town, and after taking his doctor's degree in 1825, settled as a physician in Amsterdam. In 1826 he removed to Rotterdam, where he lectured on physics and chemistry, and in 1840 was appointed Professor of Chemistry at Utrecht. Here he discovered Proteïn (q. v.)—a discovery which has carried his name over all Europe and America. M. is the author of numerous valuable works upon the chemistry of wine (1856; Eng. trans. by Dr. Bence Jones), of beer (1858), &c., and also upon physiological and agricultural chemistry.

Mule (Old Eng. *mul*; Lat. *mulus*, perhaps from the 'mu'-ing or 'whinnying' sound it makes) is the name specially given to the hybrid animal produced by the union of the ass with the mare; the *hinny* being the product of interbreeding between the female ass and stallion. The general features of the body are those of the horse; but in the head, ears, and tail the M. resembles the ass. It has the docility of the former with the endurance of the latter. Its reputed stubbornness arises most probably from the ill-treatment to which it is usually subjected. In Spain and Italy it is still largely bred. Of old mules were used as beasts of burden and of conveyance in Palestine and elsewhere; and in S. America they form in the present day the chief means of communication, and are also employed to convey goods between civilised and remote districts. Their surefootedness renders them invaluable for traversing mountainous paths. Males are more numerous than females. They appear to be sterile when bred together, but it is certain that when bred either with the horse or ass, they may produce young.

Mull (Gael. *maol*, 'a headland'), the second largest of the Inner Hebrides, separated from Argyllshire by the Sound of M. (2 miles wide), has an extremely irregular coast-line of nearly 300 miles, and is 29 miles long by 28 broad. Estimated area, 237,000 acres; pop. (1871) 5947. The prevailing rocks are basalt, gneiss, granite, and blue syenite, and the surface is mountainous, attaining in Benmore an elevation of 3168 feet. Of several freshwater lakes, the largest, Loch Eriss, is 4 miles long. The crops (oats, barley, flax, and potatoes) only suffice the wants of the inhabitants, but sheep and cattle are exported in considerable numbers. The fisheries employ a great portion of the inhabitants. Tobermory (Gael. 'Well of St. Mary'), the only village of any size, has a small harbour, and a pop. (1871) of 1344. The antiquities of the island are the castles of Aros, Duart, and Moy, and a few caans and barrows.

Müller, Wilhelm, one of the most charming lyric poets of Germany, was born at Dessau, 7th October 1794, studied philology and history under F. A. Wolf at Berlin (1812), acted as a volunteer in the German War of Liberation (1813), took part in the battles of Lützen, Bautzen, Iainau, and Kulm, and on the conclusion of peace resumed his studies at Berlin, devoting himself especially to the Old German language and literature. In 1817 he visited Italy, and some time after his return was appointed ducal librarian at Dessau, where he died, 1st October 1827. M. had a certain nobility of character and love of comprehensive culture which reappear in his illustrious son; but it is as a poet he will be remembered by his countrymen. The first work that distinctly evinced his poetic power was *Gedichte aus den hinterlassenen Papieren eines reisenden Waldhornisten* (2 vols. 1821-24). His *Lieder der Griechen* (5 parts, 1821-24), simultaneously issued, show still finer work. But he is seen at his best in his *Lyrische Spaziergänge* (1827). They are marked by an inward truth and feeling, a fresh and vivid power of description, a noble ardour for the rights of the people, and a

singular melody of language. A collection of his *Gedichte* was published at Leipsic in two vols. in 1837 (latest edition 1869). Schwab published M.'s *Vermischte Schriften* (5 vols. 1830), with a biographical memoir.—**Friedrich Max M.**, a son of the preceding, was born at Dessau, 6th December 1823, studied Sanskrit at Leipsic under Hermann Brockhaus, and published a translation of the *Hilopadesa* (1844). After attending courses of Bopp and Schelling at Berlin, he proceeded to Paris (1845), where, at Burnouf's suggestion, he commenced to collect materials for an edition of the *Rigveda*. With this object he came to England (1846) to collate the Sanskrit MSS. in the Bodleian and East India House, and in 1847, on the recommendation of Bunsen and Wilson, the East India Company undertook the cost of publishing his work (6 vols. Oxford Clar. Press, 1849-74). Settling at Oxford (1848), Max M. became successively Deputy Taylorian Professor (1850), honorary M.A. and member of Christ Church (1851), Taylorian Professor and full M.A. (1854), a Curator of the Bodleian (1856), and a Fellow of All Souls (1858). A candidate for the Sanskrit professorship (1860), Max M. lost his election through the 'country parsons,' men who cared little for philology, and scented rationalism in a fellow-countryman of Strauss; but raised in 1868 to a newly-founded chair of comparative philology, he refused a call to the University of Strassburg (1872). He is one of the eight foreign members of the French Academy (1869), and has received honours and titles from almost every learned society throughout the world. If not the founder of the science of philology in England, Max M. has done more to popularise its study than any other author. His works, written in faultless English, and abounding in striking familiar illustrations, are only marred by an occasional dogmatism that has involved him in unworthy disputes with Mr. Darwin and Professor Whitney. They include *A Letter to Bunsen on the Classification of the Turanian Languages* (Lond. 1844); *History of Ancient Sanskrit Literature* (Lond. 1859); *Lectures on the Science of Language*, two series, delivered at the Royal Institution in 1860 and 1863 (8th ed. 1875); *Sanskrit Grammar* (Lond. 1866); *Sacred Hymns of the Brahmins* (1869); and various essays, collected in *Chips from a German Workshop* (4 vols. Lond. 1867-75). Max M. is also author of an exquisite novelette, *Deutsche Liebe* (Leips. 1857; Eng. trans. Lond. 1876).

Müller, Johann, a German physiologist, was born at Koblenz, July 14, 1801. He studied medicine at Bonn, where he graduated as doctor in 1823, and where in 1826 he became extraordinary, and in 1830 ordinary professor of physiology. In 1833 he resigned this for the corresponding chair at Berlin, which he held till his death, April 28, 1858. M. was one of the founders of the physico-chemical school of physiology, and was the author of several valuable works, of which the most important are *Handbuch der Physiologie des Menschen* (3d ed. 1837-40), and *Ueber den feinern Bau und die Formen der krankhaften Geschwülste* (1838).

Müller, Johann von, the historian of Switzerland, was born at Schaffhausen, January 3, 1752, entered the University of Göttingen (1760), and in 1772 became Professor of Greek in the Gymnasium of his native town. He removed to Geneva (1774), accepted the chair of Statistics in the Collegium Carolinum at Kassel (1781), and became librarian and aulic councillor to the Elector of Mainz (1786), by whom he was ennobled (1791). In 1792 he entered the service of Austria, to quit it in 1804 for the posts of Councillor of War and Historiographer to the King of Prussia. An interview with Napoleon (November 20, 1806) was followed by a summons to Fontainebleau, and in 1807 M. accepted office under Jerome, the newly established King of Westphalia. He died at Kassel, May 29, 1809. Besides his great work, *Geschichte der Schweizer* (5 vols. 1780-1808; continued by Blozheim and Hollinger), M. published *Bellum Cimbricum* (Zur. 1772), *Vierundzwanzig Bücher allgemeiner Geschichten* (3 vols. Tüb. 1811), and numerous treatises, contained in his *Sämmtliche Werke* (2d ed. 40 vols. Stuttg. 1831-35). Of four biographies of M., the best are those by Woltmann (Berl. 1810) and Roth (Sulzb. 1811.)

Müller, Karl Otfried, a famous German archæologist, born at Brieg, in Silesia, August 28, 1797, studied at Breslau and Berlin, and in 1817 became Professor of Ancient Languages at the Magdalenum of the former city. Two years later, having accepted a call to the chair of Archæology in the University of

Göttingen, he visited the art collections of Dresden (1819), and of France and England (1822), and then settled down to fifteen years of hard and successful labour. The Hanoverian troubles of '37 induced him to obtain leave of absence on a scientific journey, and after a tour through Italy, Sardinia, and the Peloponnesus, he died at Athens, August 1, 1840. M. was a keen and profound critic, though he sometimes shows an over-fondness for arriving at the reason of everything. His writings include *Orchomenos und die Minyer* (Bresl. 1844), *Die Dorier* (2 vols. Bresl. 1824; Eng. trans. by Sir George C. Lewis and Henry Tuffnell), *Die Etrusker* (2 vols. Bresl. 1828), *Handbuch der Archæologie der Kunst* (Bresl. 1830), and *History of the Literature of Ancient Greece* (Lond. 1840), undertaken at the request of the English 'Society for the Diffusion of Useful Knowledge,' and left unfinished at the author's death. Sir George Lewis and Dr. Donaldson translated the work into English. The German version was edited from the author's MS. by his brother Edward (2 vols. Bresl. 1841). See Lücke, *Erinnerungen an O. M.* (Gött. 1841).—**Julius M.**, brother of the preceding, born at Brieg, April 10, 1801, studied at Breslau, Göttingen, and Berlin, and became pastor of Schönbrunn and Rosen in Silesia (1825). He was appointed Professor of Dogmatics and Ethics at Marburg (1835), and at Halle (1839), an office which he still (1877) holds. The author of *Das Christliche Leben* (Bresl. 1826) and *Die Christliche Lehre von der Sünde* (Bresl. 1839; Eng. trans. Edinb. 1836), M. is also known as the founder, with Nitzsch and Neander, of *Die Deutsche Zeitschrift für Christl. Wissenschaft und Leben* (1850).

Mull'et (*Mugil*), a genus of *Teleostean* fishes, belonging to the *Acanthopteros* section of that order, and to the family *Mugilidae*. It has large scales, two dorsal fins placed widely apart, and small teeth. The most common M. is the grey M. (*Mugil capito*) of the S. coasts of Britain, and which also occurs in other seas of Europe. Its colour is bluish grey above, with a dark spot at the base of each pectoral fin. The grey M. is active and wary, and is highly valued as a food fish. The average length is 15 inches. Other and nearly allied species are the *M. cephalus*, found in the Mediterranean Sea, and the *M. chelo*. The *M. albulus* of the N. American coasts resembles the British species. To the genus *Mullus* belong the *Surmulletts*, also named mullets. The species of *Mullus* are nearly related to the Peich (q. v.). Two long filaments project from the under jaw, the body is long and compressed, and the upper jaw has no teeth. Of this group the surmullet (*Mullus surmulletus*), or common red M. of British seas, is a well-known example. It attains a length of 14 inches, is of a bright red colour, and is marked with three yellow lines. The famous M. of the Romans was probably the red M. (*M. barbatus*) of the Mediterranean Sea.

Mull'et, or **Moll'et**, in Heraldry, one of the marks of cadency, a charge supposed by some to have been originally designed to represent the rowel of a spur. It is often pierced at the centre, and has five points, while the *star*, of similar shape, has six. M. is also a term for a fish.

Mullingar, the county town of W. Meath, Ireland, on the Royal Canal, near the river Brosna, and 50 miles W.N.W. of Dublin by rail. It has an Episcopal church (1813), a Roman Catholic, a Wesleyan, and a Presbyterian chapel. It has four large horse and cattle fairs in the year. Pop. (1871) 5103, of whom 4090 are Roman Catholics.

Mullions (Old Eng. *monyal*, Fr. *meneau*, from Lat. *munio*), upright shafts dividing the lights of windows, screens, &c., were variously moulded, and first became common in Early English.

Mulock, Dinah Maria (Mrs. Craik), a popular English novelist, is the daughter of a clergyman, and was born at Stoke-upon-Trent in 1826. Her earlier novels, *The Ogilvies* (1849), *Olive* (1850), *The Head of the Family* (1851), *Agatha's Husband* (1852), &c., led the way to her great success with *John Halifax, Gentleman* (1857), an admirable novel both in concep-

Gothic window, showing Mullion.

tion and tone. The reputation she had by this time achieved as an earnest and thoughtful writer, and accurate portrayer of middle-class life, has since been well maintained by *Mistress and Maid* (1863), *A Noble Life* (1866), *Hannah* (1871), *The Laurel Bush* (1876), and other novels. She has also written *Fugitive Poems* (1860), *Sermons out of Church* (1875), besides many short tales and sketches, and books for the young. She received a pension in 1864, and married Mr. George Lillie Craik in 1865.

Mulready, William, R.A., an artist of great celebrity, was born at Ennis, Ireland, 1786, and became a student of the Royal Academy when fifteen. His first pictures were very ambitious, but he soon selected the smaller canvasses his name is associated with, and painted such subjects as 'The Rattle' (1808), 'The Roadside Inn' (1811), 'Punch' (1813), 'Idle Boys' (1815). On the appearance of the last he was made Associate, and next year he became R.A. M. died at Bayswater, 7th July 1863. One or two of his most finished specimens are 'The Wolf and the Lamb' (1820), 'The Cannon' (1827), 'The Whistonian Controversy' (1844), 'Choosing the Wedding Gown' (1846), 'Blackheath Park' (1852). His collected works were exhibited in 1848. M.'s is a fame more than insular. His drawing was faultless, and he painted with great delicacy of touch, and a luminous splendour of colour, lacking which all the engravings of his works appear feeble.

Multiplepoinding, a term of Scotch law, denoting a kind of action which may be brought by the holder of money or effects claimed by different persons, to dispose of the same by judicial authority. Each claimant is cited to appear in court, and there to state his ground of claim.

Multiplication, one of the fundamental rules of algebra and arithmetic, by which is found the number which contains a given number a given number of times. Thus, 3 times 4, or 4 taken 3 times, is 12, and this is obviously the same as 3 taken 4 times. The symbol of M. is \times , so that $3 \times 4 = 12 = 4 \times 3$. 12 is the product of 3 and 4. Generally if a and b are two numbers, $ab = ba$; or, in technical words, M. is said to be commutative. If there are several numbers to be multiplied together, it does not therefore signify in what order the M. is made, the resulting product is always the same. Sir W. R. Hamilton, however, has extended the meaning of M. in his calculus of Quaternions (q. v.). He has conceived it as an operation, and except when the quantities are Scalar (q. v.)—which includes all ordinary numbers—there is a material difference as to which quantity is the operator and which the operand. Thus, if A and B are vectors or quaternions, AB is in general different from BA .

Multivalve, the name given to the *Shell* (q. v.) of a single family (*Chitonidae*—see CHITON) of Gasteropodous Molluscs, from the fact that it consists of eight pieces, disposed in pairs. All other molluscs have either two pieces or valves in the shell, when it is named *bivalve* (oyster, cockle); or one piece, when it is termed *univalve* (whelk, snail).

Multure is, in Scotch law, a quantity of grain, manufactured or in kind, given to the proprietor or tacksman of a mill in return for grinding corn. The M. is payable by every one having his corn ground at the mill; but the tenants and proprietors of some lands are bound to use a particular mill, and the lands so bound are termed the *Thirl* or the *Sucken*, and the tenants or proprietors the *insucken multurers*. Those using the mill without being bound to do so are termed the *outsucken multurers*. See THIRLAGE.

Mummy. See EMBALMING.

Mummy Wheat. At one time it was believed that the grains of wheat found in Egyptian graves were capable of growth!—hence the name M. W. Of course, reliable experiments at once showed the fallacy of such an idea. Two varieties have been collected from different tombs, both pertaining to those still cultivated in the country. It was found that the form of the grain had not changed, and the specific weight was also the same. The flour was bitter tasted and bituminous. On being sown in moist soil, the grains became soft, swelled during the first four days, reached their maximum on the seventh, but on the ninth decomposition was complete. No trace of germination was at any time discoverable. Similar negative results occurred with barley.

Mumps is the popular name for an inflammation of the parotid gland, probably specific and occasionally contagious. The technical name is *Parotitis*, or *Cynanche Parotidæa*. Inflammation of the parotid, like that of any other gland, may take place as the result of exposure to cold or wet, or in the course of enteric and typhus fever, and one or both sides of the neck may be affected. The swelling, stiffness, and pain may be considerable, but suppuration seldom occurs, unless it be in the lymphatic glands of the neighbourhood. There is, however, a form of the disease which is evidently zymotic and communicable, and which prevails in certain localities rather than others; so that local causes or local hygienic conditions have something to do with its origin. M. is very common in Shetland, and seems to be endemic there. The disease has fourteen days of incubation, which may be extended to three weeks, but seldom longer than twenty-two days. The first symptoms are febrile, associated with pain and uneasiness in the region of the parotid. Beneath one or both ears there is swelling and hardness, which generally extends to the submaxillary glands, the tonsils, and the pharynx, rendering swallowing difficult. During the subsidence of M. the testicles or the mammae frequently swell; and, in some cases, the gastro-enteric mucous membranes, or the cerebral membranes, become implicated, and death ensues. The disease runs a definite course, and generally terminates favourably.

Münchhausen, Hieronymus Karl Friedrich, Freiherr von, born in 1720 at Bodenwerder in Hanover, was a cavalry officer in the Russian campaigns against the Turks from 1737 to 1739, after which he lived on his family estate at Bodenwerder till his death in 1795, and became famous for telling highly exaggerated and incredible stories of his adventures and exploits in hunting, war, and travel. In 1785 there was published in London by Rudolf Erich Raspe, who had been a professor at Kassel, a collection of such tales under the title *Baron M.'s Narrative of his Marvellous Travels and Campaigns in Russia*, which in two years went through five editions, and received extensive additions from older works, such as the *Faciles* of Bebel (1508) and the *Deliciae Academicæ* of Lange (1765). In 1857 Bürger published at Göttingen a German version, the second edition of which (1788) contains numerous other additions, partly by Lichtenberg. See ELLISSEN'S *Des Freiherrn von M. wunderbare Reisen und Abenteuer* (10th ed. Göt. 1870), and *Avantures du Baron de M.*, illustrated by Doré (Par. 1862).

Mün'den, a town of Prussia, province of Hanover, at the confluence of the Fulda and Weira, 351 feet above the sea, and 17 miles N.E. of Cassel by rail. The Schloss dates from 1566. M. has a considerable commission trade, and manufactures of alum. Pop. (1875) 5616.

Mundi' (*Mandi'*), the capital of a native state of the same name in the Punjab, India, in the Jullundhur Doab, at the confluence of the Sukeit River with the Beas, 220 miles N. of Delhi. The palace is surrounded by excellent fruit and flower gardens. Pop. 7300.—The state of M., which lies among the hills, almost enclosed by the district of Kangra, has an area of 1000 sq. miles, and a pop. of 135,000. Its revenue is £36,500, and its tribute to the British, £10,000. M. has salt mines, and iron is found. The ruling family, who are Rajputs, came under British protection after the first Sikh War of 1846, and the state has lately been under British administration.

Mund'la (*Mandla*), the chief town of the district of the same name, Central Provinces, India, on the right bank of the river Nerbudda, by which it is almost surrounded, 50 miles S.E. from Jabulpore and 510 W. of Calcutta. It was the former capital of the Gond kingdom, and possesses ruined fortifications, and many ghauts or bathing-places on the river.—The district of M., which is very mountainous, has an area of 4719 sq. miles, and a pop. (1872) of 213,018. It forms the stronghold of the aboriginal race called Gond; agriculture and trade are very backward, but the soil in the valleys is extremely fertile. Tigers abound.

Mungo. See SHODDY.

Mungo, Saint. See KENTIGERN, SAINT.

Mongoose, or **Mongoose** (*Herpestes griseus*), a species of Carnivorous quadrupeds, belonging to the family of the Ichneumonons (q. v.), and sometimes named the Indian Ichneumon. It

attains the size of a cat, and is of grey colour. Another species, named the banded *M.* (*Mungus fasciatus*), inhabits Africa. The Indian species is famous as a destroyer of that most deadly of snakes, the Cobra (*Naja tripudians*), and combats between it and the reptile almost invariably result in the death of the latter. Some observers think that the fur of the *M.* protects it; others that the *M.* may be bitten, but that, by eating some herb, it counteracts the effects of the poison; while a more likely theory is that the agility of the animal enables it to keep out of harm's way, and that it seizes and despatches the snake before the latter has time to bite.

Mun'ich (Ger. *München*), the capital of Bavaria, and by far the largest city of S. Germany, lies on the left bank of the Isar, in a wide, sterile plain, near the W. base of the Alps, and 1700 feet above the sea. One of the chief art centres of Europe, it is unrivalled among the cities of the empire for the number and splendour of its churches and secular buildings. It is in great part a modern city, its glorious architecture being due to Ludwig I., who expended £1,050,000 in beautifying and extending his capital, the population of which has quadrupled during the present century. Near the heart of the city, and on the Max-Joseph Platz, which is the great centre of traffic, and contains the statue of King Max by Rauch (1825), stands the royal palace, consisting of three parts—the Königsbau, the Festsaalbau, and the Alte Residenz, or old palace. The Königsbau, or modern residence, built by Klense (1826-33) in imitation of the Palazzo Pitti in Florence, is adorned with marble sculptures, and with the famous Nibelungen frescoes by Schnorr; the Banqueting-Hall (1832-42), in Renaissance style, has a fine balcony resting on ten Ionic columns, and encaustic mural designs by Schwanthaler; the Alte Residenz (1600-16) contains many beautiful bronze statues, and is fitted up magnificently in the style of the 17th c. The palace-garden (*Hofgarten*) is girt on two sides with open arcades containing frescoes by Rottmann, Kaulbach, &c. Adjoining the palace are the *Hof-theater* (1825), accommodating 2500 spectators, and the beautiful All Saints' Church (1837), in the Byzantine style. Among the other great churches of *M.* are the Ludwigskirche (1829-42), with a façade flanked by two towers 234 feet high, and containing the 'Last Judgment,' by Cornelius, 66 feet by 40; the Basilica (1850), the grand resting-place of Ludwig I. (died 1862); the Frauenkirche or cathedral of the Archbishop of *M.* and Freising, a brick building (1468-88), surmounted by two incomplete towers 357 feet high; the court church of St. Michael (1583), in Romanesque style; and the Marihilfikirche (1830-39), in the suburb of Au, which has an open tower 290 feet high, and beautiful stained glass windows. Ludwig's Strasse, lined almost continuously with public buildings, runs N. from the palace to the famous Siegesthor, or 'Gate of Victory,' an imitation of the Arch of Constantine at Rome (1840). On this street are the Odeon, for concerts, designed by Klense (1828); opposite the Odeon, the statue of Ludwig I., erected by the 'grateful city of *M.*' in 1862; the palaces of the Duke of Leuchtenberg and of Duke Max, and the War-Office, all by Klense; the library, in Florentine style, built by Gärtner (1832-42), and containing 800,000 vols. and 22,000 MSS.; and the university (founded at Ingolstadt in 1472, and transferred hither in 1826), which is associated with various medical and other schools, and had in 1876 116 professors and teachers and 1203 students, and a library of 160,000 vols. The Bavarian National Museum, founded by Karl Max II. in 1855, and erected 1858-66, contains magnificent art and industrial collections. The Old Pinakothek (Gr. 'picture repository'), erected in 1826-36, is a splendid gallery of 1400 pictures, including the Boisseree collection of early German works, the grand Rubens collection from Düsseldorf, Rembrandt's scenes from the Passion, and many fine specimens of the Dutch and the Spanish schools. It has also 168,000 engravings, and 9000 drawings by old masters (among which are five by Raphael, ten by Fra Bartolommeo, and sketches by Rembrandt, Dürer, Holbein, &c.), and 1300 Grecian and Etruscan vases. Other art institutions are the New Pinakothek (1846-53), exclusively for modern pictures; the Glyptothek (1805-16), consisting of eleven halls, containing rare ancient sculptures, and two containing modern marbles; the Schwanthaler Museum of Sculpture; the Exhibition (1845) for the annual display of works by *M.* artists; the Academy, with valuable art and technical collections, and a cabinet of 20,000

Greek and Roman coins; the Stained-Glass Institution, with many fine modern specimens; and the Bronze Foundry, with its extensive collection of models. To the S.W. of the city, near the Karl Gate, stands the Ruhmeshalle ('Hall of Fame'), a grand Doric edifice (1853), within which are the busts of seventy-six renowned Bavarians; and in front of it is the allegorical figure of Bavaria—a female colossus 66 feet high, modelled by Schwanthaler. The English Garden, laid out by Count Rumford, is an extensive park with fine old trees, watered by two arms of the Isar. *M.* is well endowed with benevolent institutions, and has three gymnasia, four Latin schools, an academy of fine arts, a music conservatory, &c. Among the special industries are bronze-casting, glass-staining, photography, and the making of scientific instruments. Some fifteen large breweries produce yearly about 15,400,000 gallons of the famous Bavarian beer. There are also manufactures of machinery, cottons, woollens, damasks, paperhangings, pianos, jewellery, porcelain, &c. Pop. (1875), with the suburbs Neuhausen, Schwabing, and Unterschelling, 211,812. *M.* was made a mint and custom town by Heinrich the Lion in 1152. The territory is said to have belonged to the monks of Schäftlarn, whence the name *Forum ad Monachos*, later *München*. The Wittelsbach princes made the town their residence (from 1253), and it was in great part destroyed by fire in 1327. Its fortifications were removed by Karl Theodor (1772-99), and it was captured by the French in 1800. The improvements by which the city has been transformed were begun by Maximilian I. and greatly extended by Ludwig I. and Maximilian II. See Forster's *München* (7th ed. *Mun.* 1858), Burgholzer's *Geschichte von M.* (2 vols. *Mun.* 1796, and the works of Hauff (1865), Steub (1863), Noe (1865), and Berlepsch (1870).

Municipality is, in law, a town or city having certain privileges of self-government. The term also denotes the governing body, or municipal corporation (see CORPORATION). Municipal corporations, with the exception of that of London (see LONDON, LAWS REGARDING), are regulated by 5 and 6 Will. IV. c. 76, by which all previously existing laws, usages, grants, and charters are abolished (see BURGESS). The acts applying to corporations specified in the schedule of the Act in question are extended by 16 and 17 Vict. c. 79 to corporations constituted subsequent to the passing of that Act. The law relating to 'elections and divisions of boroughs into wards' was amended by 22 Vict. c. 35. Under that Act, on petition to her Majesty by two-thirds of the council of any borough, it may be divided into wards, or the number and boundaries of boroughs already so divided may be altered. Notice of petition must be given in the *Gazette*. See ELECTORS, QUALIFICATIONS OF.

Mun'iment House or Room, a strong, fire-proof room for the safe keeping of such *muniments* of property as records, charters, seals, and title-deeds.

Mun'jeet (*Rubia cordifolia*) is cultivated exclusively in Asia, especially in India, where it has been used as a dyestuff for a long period, either alone or mixed with other dyes, to produce a variety of red shades. It has been imported into Britain from time to time, but has not been extensively employed, as the colours produced from it are neither so bright nor so fast as those obtained from *R. tinctorum*, which possesses different tinctorial principles.

Munkacs', a town of Hungary, capital of the comitat of Beregh, on the Latorcza, 67 miles N.E. of Debreczin by rail. It has manufactures of cloth, furs, and hosiery; and iron, alum, and rock-crystals ('Hungarian diamonds') are found in the neighbourhood. On an isolated rock (310 feet high) 2 miles E. of the town, stands the strong fortress of *M.* (1359), now converted into a state prison. Pop. (1869) 8602.

Munnipore' (*Manipur*), a native state on the extreme N.E. frontier of our Indian Empire, situated among the mountains that bound Burmah. Area of the 'M. valley' 650 sq. miles; pop. about 56,000; revenue about £5000. The area occupied by subject hill tribes is estimated at 8000 sq. miles. The exports are india-rubber, ivory, wax, elephants, and timber. As early as 1762 a treaty was made with the Rajah against the Burmese; a political agent was appointed in 1835, whose duties have chiefly to do with freedom of trade and intercourse with the neighbouring wild tribes.

Munro, the name of two distinguished Indian officers.—(1) **Sir Hector M.** originally went to India as a major in H.M.'s 89th Regiment. He signalled himself by suppressing the first mutiny of the Bengal sepoy in the cantonments at Patna in 1764. A battalion attempted to desert; they were captured, and twenty men of the grenadier company were blown from guns. In the same year, and with the same soldiers, he won the decisive battle of Buxar against the Nawab Vizier of Oude. This made the British supreme in Hindustan, and the Mogul Emperor, Shah Alum, presented himself at their camp. M. was afterwards commander-in-chief at Madras during the war against Hyder Ali, 1780-82, but was superseded by Sir Eyre Coote.—(2) **Sir Thomas M.**, also a general, but better known for his civil administration, was the son of a Glasgow merchant, and was born in that city, 27th May 1761. In 1779 he proceeded to Madras as an infantry cadet, distinguished himself in the wars against Hyder Ali and Tippoo Saib, and in 1800 was promoted to the rank of major. From 1800 to 1808 he governed the districts of Bellary and Cuddapah, ceded by the Nizam of Hyderabad, and in 1818 he took a prominent part in the last Mahratta war. He was appointed Governor of Madras in 1820, with the rank of major-general, and was chiefly instrumental in introducing the *Kyotowarry* Settlement (q. v.). In 1825 M. was created a baronet of the United Kingdom. Attacked by cholera when on a farewell visit to the ceded districts over which he had long ruled, he died at Putticondall, near Gtiti, 6th July 1827. See Gleig's *Life of Sir Thomas M.* (3 vols. 1830).

Munster, the largest of the four Irish provinces, occupying the S.W. portion of the island, is bounded N. by Connaught, E. by Leinster, and W. and S. by the Atlantic. It embraces the six counties of Clare, Cork, Kerry, Limerick, Tipperary, and Waterford; and has an area of 9273 sq. miles, of which, in 1876, 5398 were in pasture and 1968 under tillage. From 1841 to 1871 the population fell from 2,396,161 to 1,393,485. In the Lakes of Killarney M. contains the most beautiful Irish scenery, and its bogs are neither numerous nor extensive. Before the English conquest it was an independent kingdom. It was divided into counties under Henry VIII.

Münster, a town of Prussia, province of Westphalia, on the brook Aa, and at the beginning of the M. Canal, 65 miles N.E. of Düsseldorf by rail. It has a mediæval appearance, most striking among the arcades and gabled houses of the Principal-Markt and Roggen-Markt. Of its fourteen churches, the finest are the Cathedral (1225-1261), a combination of the Gothic and Romanesque styles, the Ludgerikirche (founded in 1170, and rebuilt in the Gothic style after a fire in 1838), the Liebfrauen or Ueberwasser-Kirche, with a fine tower, the Church of St. Mauritz, a Romanesque building of the 12th c., and the beautiful Gothic Lambertikirche of the 14th c., from the S. side of whose tower hang the three iron cages in which the bodies of the Anabaptist leaders were displayed. The Rathhaus, of the 14th c., has a fine Gothic façade, and contains the 'Friedenssaal' (restored 1864), where the Peace of Westphalia was signed in 1648. Behind the Schloss (1767) is a botanical garden belonging to the academy, which was a university till 1818. The chief industries are glass-painting and the manufacture of woollens and cottons, and there is a large trade in Westphalian hams and rye-bread, and in Baumberg sandstone. Pop. (1875) 34,705. M. appears first in the time of Karl the Great under the name Mimigardeword. Karl gave it as a dwelling-place to St. Ludger, Bishop of the Saxons, and the earliest buildings rose round his *Monasterium*, from which the town takes its present name. M. is a bishop's see of great antiquity. In the 13th and 14th centuries it was a flourishing Hanse town. In 1533-34 it suffered much from the excesses of the Anabaptists (q. v.), and in 1650 it came under the warlike Prince-bishop Von Galen. It subsequently shared the fortunes of Westphalia (q. v.). See Erhard, *Geschichte M.'s* (Münst. 1837); and Geisberg, *Merkwürdigkeiten der Stadt M.* (Münst. 1866).

Muntjac (*Cervus Muntjac*), a species of deer found in Java and other islands of the Eastern Archipelago, and differing from the other members of the deer family in the possession by the males of prominent upper canine teeth and of straight horns, each provided with a little branch. The M. resembles the Roebuck (q. v.).

Münzer, Thomas, a religious fanatic of the Reformation period, and one of the leaders of the Anabaptists (q. v.) was born at Stolberg in the Harz in 1489. After some time spent as a schoolmaster at Aschersleben, and convent chaplain at Halle, he appeared at Zwickau as a preacher in 1520. Thence he passed to the Hussites in Bohemia, and in 1523 was at Allstedt in Thuringia. Everywhere he displayed an intolerant fervour. Not only the Papacy was denounced; he assailed the servile, letter-worshipping, half-and-half ('*knechtische, buchstäbliche und halbe*') character of the Protestant movement, upheld the superiority of the 'inner light,' and demanded a radical reformation in ecclesiastical and political affairs, universal freedom, and a community of goods. The peasants and the populace were enchanted. Expelled from Allstedt by the Elector, Friedrich of Saxony, and Johann, Duke of Weimar, M. went first to Nürnberg, thence to Schaffhausen, and finally returned to Thuringia, settling at Mühlhausen, where he overthrew the civic power, and plundered the monasteries and houses of the rich. The violence of his actions and his language roused the German princes to arms. The Elector Johann, Duke Georg of Saxony, the Landgraf Philipp of Hessen, and Duke Heinrich of Brunswick, sent a large force against M. and his followers, who were defeated with great slaughter at Frankenhausen, 15th May 1525. M. fled in dismay, and sought to hide himself, but was captured, carried to Mühlhausen and beheaded with twenty-four of his chief accomplices. See Strobel, *Leben, Schriften und Lehren Thom. M.'s* (Nürnberg. 1795), and Seidenmann, *Thom. M.* (Dresd. and Leips. 1842).

Muraena (*M. Helena*), the name given to a species of Eel (q. v.) famous in classical times. It is found in the Mediterranean Sea, and has been occasionally taken off the British coast. The M. has no pectoral fins, and the gill-openings are represented by mere slits. There is a single row of teeth on the nasal bone. The M. was highly esteemed by classic epicures on account of the peculiar flavour of the flesh. It attains an average length of 1½ feet. Its colour is a golden yellow, mottled with bands and markings of purple and brown.

Mural Circle is an astronomical instrument of large size, consisting of a telescope attached to a graduated circle which is firmly fastened to a solid wall of masonry. It is fixed in the meridian plane, and is intended for measuring angular distances in the meridian. Originally the telescope was used simply with a graduated arc or quadrant, but the circles constructed by Troughton in the beginning of the present century showed the many advantages which a complete circle has over an arc. The instrument cannot be used for accurately determining right ascensions; and consequently it is now giving place to the more complete structure known as the Transit Instrument (q. v.).

Mural Crown (Lat. *corona muralis*), among the Romans one of the highest military decorations, a crown of gold, surmounted by turrets ('*muri pinnis*'), given to the first who scaled the wall of a besieged city.

Murat, Joachim, son of a tavern-keeper, was born 25th March 1771, at La Bastide-Fortunée, received a liberal education at the college of Cahors, went to Toulouse to join the priesthood, but followed a cavalry regiment for two years, and entered at Paris the Constitutional Guard of Louis XVI. On the 30th May 1791 he attained the grade of sub-lieutenant and distinguished himself by his hot partisanship of the Revolution, his ardent taking shape in the desire to change his name to Marat. Passing through the different grades until he became colonel, M. was appointed (Oct. 5, 1795) by Napoleon to a mission of some importance in connection with a movement of cavalry in the Tuileries Gardens, and in the following year went to Italy with him as a chief of brigade. He distinguished himself at every point of the campaign, more especially at the siege of Mantua, at Roveredo, and in executing the passage of Tagliamento. On the 19th May 1798, M. embarked with Napoleon, and (Feb. 1799) took charge of a cavalry regiment *en route* for Syria. He led the assault at the siege of Acre, penetrated to Gennesaret, and Napoleon wrote to the Directory that to M. was chiefly due the triumph of Aboukir. In Oct. 1799 he was created a general of division. Having dispersed, on the 18th Brumaire, the Council of Five Hundred at St. Cloud, M. was rewarded by the hand of Caroline, youngest sister of Napoleon, and appointed Commandant of the force. A brilliant march to Milan brought

him fresh honours (1801); in 1803 he was made President of the Electoral College of Lot, in 1804 Governor of Paris and Marshal of the Empire, a Prince and General adorned with the great eagle of the Legion of Honour in 1805, and in 1806 Grand-Duke of Berg and Cleves. The same year saw him engaged at Jena; in 1808 he conducted operations in Spain till July, when Napoleon nominated him King of Naples. As a king he wrought consistently enough for the welfare of the people entrusted to his care, organised a fine army out of poor material, but adopted a most theatrical style of display. His position was rendered vexatious also by the interference of Napoleon, who made him feel how much he was a vassal and how little a king. They had come to an open rupture when the war with Russia again called him into the field, and he took part in the battles of Smolensk and Moscow, but after the defeat of Leipzig he returned to his kingdom and began to treat with the allies. After Napoleon's escape from Elba, M. again joined him, but was defeated at Ferrara and Tolentino, 1815. A revolt occurred at Naples, his kingship was no longer recognised, he fled to Ischia, from that to France, and finally made Corsica his asylum. Driven by a restless ambition to the shores of Naples, where he claimed his crown, M. was betrayed into the hands of the populace of Pizzo, and was shot, 13th October 1815. M. was a brave and dashing soldier, with a true instinct for political freedom, but with no turn for the responsibilities of civil life which fell upon his shoulders. See Thiers' *Histoire de la Revolution, Histoire du Consulat et de l'Empire*; Léonard Gallois' *Histoire de J. M.* (1828); Coletta's *Histoire des six derniers Mois de la Vie de J. M.* (1821). He left two sons, Napoléon Achille M. and Napoléon Lucien Charles M., both of whom emigrated to the United States. The former, born 21st January 1801, settled in Florida, and died 15th April 1847. The latter, born 16th May 1803, returned to France at the Revolution of 1848, joined the party of Louis Napoleon, was appointed Ambassador Extraordinary to the court of Turin in 1849, was made a senator in 1852, a prince in 1853, and several times put forward his claim to the throne of Naples. In 1870 he was shut up in Metz with Bazaine, and on its capitulation was imprisoned in Germany. By his marriage with an American lady he has three sons and two daughters.

Muratori, Ludovico Antonicino, an Italian historian and archaeologist, was born at Vignola in Modena, 21st October 1672, and at the University of Modena acquired an extensive knowledge of ancient literature. In 1694 he became keeper of the Ambrosian Library, Milan. His uneventful life was one of incessant literary toil. In 1700 he returned to Modena as keeper of the Duke's Library, and here were composed those works which have made him known as a prodigy of learning and patience. The most famous are: *Rerum Italicarum Scriptores Præcipui* (29 vols. folio, Milan, 1723-51); *Antiquitates Italice Medii ævi* (6 vols. folio, Milan, 1738-43); *Novus Thesaurus Veterum Inscriptionum* (6 vols. folio, Milan, 1739-42); *Annali d'Italia* (12 vols. Ven. 1744-49). M. died at Modena, 23d January 1750. His complete works were published at Venice (48 vols. 1790-1810). See his nephew C. F. M.'s *Vita del celebre Lud. Ant. M.* (Ven. 1756).

Murchison, Sir Roderick Impey, one of the greatest geologists of the present century, was born February 19, 1792, at his father's estate of Tarradale, in Ross-shire, Scotland. After being educated at Durham Grammar School, he entered the army, accompanied the 36th Regiment as ensign to Spain in 1808, was one of the survivors of the battle of Coruña, and on his return to England was promoted first to a lieutenancy and then to a captaincy. He saw no more active service, and in 1815 married and retired from the army. The next two years were spent in Italy studying art. In 1818, he settled at Barnard Castle, Durham, a property which belonged to his wife, and for the next five years threw himself enthusiastically into field sports—especially fox-hunting. In the year 1824, his true life began; and his subsequent brilliant career as a man of science is directly traceable to the influence of his wife, to whom, as he himself records, he owed his fame. In this year he removed to London, attended the science lectures at the Royal Institution, and became at once greatly interested in the science of geology, then in its infancy. In 1825 he entered the Geological Society (founded 1807), where he met the leading British geologists and naturalists of the day—Sedgwick, Fitton, Greenough, Wollaston, Buckland,

Conybeare, De la Beche, Lyell, Scrope, and others. M. was elected secretary to the Society in 1825, and president in 1831. Henceforward his summers were spent in field work, for which he showed a peculiar fitness. In 1827, in company with Sedgwick, he took a rapid geological raid through Scotland, the results of which were given in a conjoint paper read before the society in 1828. The next three summers were spent amongst the secondary rocks of Central Europe, first in company with Lyell, and then with Sedgwick. In 1831 his attention was drawn to the so-called 'transition' rocks or *granwacke* of the Germans; and he commenced operations in 1833 on the Welsh frontier amongst those formations, which must always be connected with the name of M. His discovery of a marked succession of life in the 'Silurian' series is undoubtedly his greatest work. Till the year 1838, when his great work *The Silurian System* appeared (last edit. 1867), he was busily engaged in investigating and arranging those ancient formations underlying the Old Red Sandstone. In 1840, the Geological Survey of Russia was entrusted to him, De Verneuil, and Count von Keyserling, and the results of the journey are given in the joint work, *The Geology of Russia and the Ural Mountains* (Lond. 1846). His subsequent work amongst his own peculiar Silurians, and among the Permian and Devonian, sustained his now world-wide fame. His nomenclature and classification were everywhere adopted, though the latter has been considerably modified in recent times. He was a member of all the great scientific societies of Europe, was twice President of the Geological Society, presided over the British Association (of which he had from the first been one of its most active promoters) in 1846, and held the President's chair of the Geographical Society for 13 years before his death. Latterly, indeed, it is more as a geographer, and more because of his annual addresses before this society, which owes its present vitality to his untiring energies, that he is known to the general public rather than by his geological work. The marks of honour which he received from the British and from foreign Governments were many. He was knighted in 1840, made K.C.B. in 1863, and a baronet in 1866. In 1853 he succeeded De la Beche as Director-General of the Geological Survey; and in 1871 founded the M. Chair of Geology and Mineralogy in Edinburgh University. He died shortly after, on October 22, at his residence in Belgrave Square, London. Most of his papers appear in the *Transactions of the Geological Society*, or in the *British Association Reports*. His other works are *Outline of the Geology of the Neighbourhood of Cheltenham* (1845), *A General View of the Palæozoic Rocks* (1852), and *Silurian Geikie*. See *Memoir of Sir R. I. M.* (2 vols. 1875) by Professor Geikie.

Murchisonia, a genus of fossil Gasteropods belonging to the family of the 'Ear-shells' (*Heliotidae*). They are confined in their distribution to rocks ranging from the Lower Silurian to the Permian. *M. gracilis* (L. Silurian) is a familiar species. The shell is long and spiral; its outer lip is notched; and the surface of the shell is frequently sculptured.

Murcia, an ancient kingdom and province in the S.E. of Spain, bounded S.W. by Granada and Andalusia, N.W. by La Mancha, N.E. by Valencia, and S.E. by the Mediterranean. Area, 10,449 sq. miles; pop. (1870) 660,040. With the exception of the N.E. plateau, the country is generally mountainous. As a whole the soil is poor and badly watered; and only in the valleys through which the Segura and its tributaries flow, or in the ridge-compacted plains of Lorca, Albacete, Chinchilla, and Almansa, is it at all productive. The valley of the Segura is especially fertile—wheat, maize, silk, hemp, oil, wine, oranges, pepper, &c., being among its products. Goats, sheep, and swine, are profitably reared. Mineral springs abound; and of minerals, sulphur, alum, and the ores of iron, lead, and copper, are found in quantity. M. belonged to the Moors from 711 to 1241 A.D., when it was subjugated by Ferdinand III. of Castile. It now consists of the two provinces Albacete and Murcia.—**M.**, the capital of the modern province of the same name, lies on the left bank of the Segura, 28 miles N.N.W. of Cartagena by rail. A canal connecting these two places is (1877) in course of construction. M. has several fine modern buildings, notably the cathedral with its pillared tower, the corn exchange (Alhondiga) with 140 marble columns, and a flourishing silk manufactory. Silk spinning and making mats, baskets, cordage, &c., from the esparto-rush, are its chief industries; and

it furnishes red pepper to nearly all Spain. The Jardin de Florida Blanca forms a splendid promenade; and the Huerta of M. rivals in its beauty and fertility that of Valencia. Pop. (1860) 87,803.

Murdañ (*Mardan*), a town in the district of Peshawur, Punjab, British India, 33 miles N.E. from Peshawur. It is the permanent headquarters of the celebrated Guides Corps, more than 1000 strong, including horse and foot. In 1857 the Guides marched to the siege of Delhi, covering 580 miles in twenty-two days. M. has been the scene of the assassination of more than one British officer by Mohammedan fanatics. See Sir J. W. Kaye's *History of the Sepoy Mutiny* (vol. ii. Lond. 1860).

Murder is the crime of killing a human being with malice aforethought. Intention to kill any one, proving the cause of death of a human being, is M.; thus if A shoot at B, and miss him, but kill C, A is guilty of M. To incite any one to suicide is M.; thus when two persons incited each other to suicide, and the means employed took effect on one only, the survivor was held guilty of M. Every person convicted of M., or of being accessory to it, is punishable with death. Rescuing or attempting to rescue a murderer, subjects the offender to penal servitude for life, and to not fewer than 15 years.

Mure or **Muir** (Latinised 'Mora,' whence 'More' and 'Moore'), the name of an ancient and distinguished family in the West of Scotland, stated (but without proof) to be of Irish origin, and an offshoot from the famous clan O'More. The earliest M. of whom history makes record is David de Mora of the house of Polkellie, Renfrewshire, who appears as a witness to a charter of Alexander II. He is supposed to have been the predecessor of Gilchrist More, who is genealogically regarded as the root of the family. Gilchrist More was forcibly deprived of the 'house and living of Rowallan' by Sir Walter Cumyn in the beginning of the reign of Alexander III., but for his bravery at the battle of Largs was knighted, and repaid in his Rowallan property; also by his marriage with Cumyn's daughter he inherited the lands of his father-in-law within the sheriffdom of Roxburgh. One of his daughters, Anicia, married Richard Boyle, of Kelburne, ancestor of the Earl of Glasgow. His son Archibald married a daughter of Sir John Montgomerie, of Eastwood, and was killed at the storming of Berwick by Edward I. in 1297. Sir William M., eldest son of Archibald, is mentioned in an indenture of truce with England during the minority of David II., and is supposed to have died about 1346. Other 'sons' (whose existence, however, or at least whose filial relationship is by no means clear) are reputed to be the founders of the Mures of Caldwell and Auchindane. Sir Adam M., son of Sir William by his marriage with the heiress of Polkellie, recovered that estate which had been disposed by his great grandfather Gilchrist to a kinsman, Ranald M. Sir Adam had two sons, Adam and Alexander, and a daughter Elizabeth, whose beauty raised her to the throne. In 1348 she was married to Robert, High Steward of Scotland, afterwards King Robert II. Her eldest brother Adam in a charter granted by Robert III. is termed 'consanguineus.' In his time, says the historian of the House, the spelling More gave place to Mure. He died in 1399. His eldest son Archibald married Euphame Kennedy, daughter of the Knight of Dumure, the ancestor of the Marquis of Ailsa, and is said to have fallen in battle with the English; but the date is uncertain. His successor Archibald (son or brother) was the father of an unfortunate Robert, who, on account of his size and strength, was known as 'the Rud of Rowallane.' 'He waysted, sold and wadset all his proper lands of Rowallane; and committed the additional folly of marrying Margerie Newtounne, 'ane drunken woman.' The 'Rud' died in 1504, leaving four sons and a daughter. The eldest, John, married Elizabeth Stewart, daughter of Lord Evandale, a descendant of the Duke of Albany, but died before his father. His successor, also named John, married Margaret Boyd of Bonshaw, mistress of James IV., and fell at Flodden in 1513. His eldest son Mungo, who married Isobel, daughter of Sir Hugh Campbell of Loudon, Sheriff of Ayr, seems to have been a pudent and worthy man, much esteemed by his kinsfolk: he was slain at the battle of Pinkie in 1547, leaving five sons and six daughters. His eldest son John took great delight in planting, 'lived gratuslie,' and died in 1591. By his marriage with a daughter of Cunninghame of Cunninghamehead he had three sons and three daughters: his

eldest son William was 'of a meik and gentle spirit, and delyted much in the study of phisick.' Sir William M., grandson of the preceding, was born in 1594. His mother was a sister of Alexander Montgomery, author of *The Cherrie and the Slae*. Before he was twenty he executed a translation of the story of Dido and Æneas from Virgil. Among the poetical addresses to King James on his visit to Scotland in 1617 is one by M. In 1628 he published a translation in English sapphics of Boyd of Trochrig's fine Latin poem *Hecatombe Christiana*, together with a small original piece called *Doomesday*. But his principal work is his *True Crucifixe for true Catholikes* (Edin. 1629). His version of the Psalms of David was executed about 1639, and was much admired. If Sir William had transmitted it to the General Assembly it might have prevented the Westminster Assembly of 1644 from recommending the version of Rous. M was a member of the Convention of 1643 by which the Solemn League and Covenant was ratified with England. He accompanied the Scotch army on its march to the South, was wounded at Marston Moor (2d July 1644), took part in the storming of Newcastle in the following August, and died in the end of 1657. Specimens of his poems, many of which are still in manuscript, may be seen in Lyle's *Ancient Ballads and Songs* (Lond. 1827). Sir William M., eldest son of the preceding, was a staunch Presbyterian, and an intimate friend of the famous Guthrie (q. v.), minister of Fenwick. He suffered greatly in his person and purse for his attachment to the national religion, and died in 1686. The male line of the house of Rowallan became extinct in the person of his son William, who married Dame Mary Scott, supposed heiress of Collarny in Fife, by whom he had three daughters, only one of whom, Jean, survived him. Jean married first William Fairlie of Brunsfield, near Edinburgh, and secondly, David, Earl of Glasgow, by whom she had three daughters. She died 30th September 1724. Her second daughter, Lady Jean Boyle M., to whom the estate of Rowallan was made over by special provision, married a son of the second Earl of Loudon. The son of this union, James M. Campbell, succeeded to the estate of Rowallan, and also became fifth Earl of Loudon. In this way the Rowallan property passed to the Loudon family.

The Mures of Caldwell are descended from a Sir Reginald M. of Abercorn and Cowdams in Ayrshire, who was possibly a son, certainly a kinsman, of that Sir William M. of Rowallan who died about 1346. The family furnishes several names prominent in Scottish history. Sir Robert M. was one of the jury appointed (1580) to try Lord Ruthven for the murder of Rizzio. He was the friend of King James VI., to whom he was related by the marriage of an ancestor with a daughter of an Earl of Lennox. William M., fourth in succession to Sir Robert, was an ardent Covenanter, and was compelled to take refuge in Holland (1667), and died in exile. His estate of Caldwell was attainted and given to General Dalzell, but by special Act of Parliament it was restored in 1690 to his second daughter Barbara. Dying without issue, she was succeeded by her kinsman William M., land of Glanderstoun; and he also dying without issue, the Caldwell property passed to his nephew William, eldest son of M. of Rhoddens in Ireland. His son William became a Lord of Session, was a friend of David Hume, wrote some tracts on questions of political economy, was lord-rector of the University of Glasgow in 1764-65, and died in 1776. His grandson, William M. of Caldwell, born 9th July 1799, was educated at Westminster School, studied at Edinburgh and in Germany, was M.P. for Renfrewshire from 1846 to 1855, and lord-rector of Glasgow University in 1847-48. He died at London, 1st April 1860. By his *Critical History of the Language and Literature of Ancient Greece* (5 vols. Lond. 1850-57), M. won for himself a foremost place in the ranks of classical scholars. The work is still an authority: it is marked by a German solidity of learning and an English sobriety of judgment. Other works of his are, *Brief Remarks on the Chronology of the Egyptian Dynasties; A Dissertation on the Callendar of the Zodiac of Ancient Egypt* (1832); and *A Tour in Greece* (1842). He also compiled and edited the valuable *Caldwell Papers*, printed for the Maitland Club in 1854. His son, Colonel William M., born in 1830, served in the Crimean War, and since 1874 has been M.P. for Renfrewshire. He is an accomplished member of the Liberal party, and, in keeping with the traditions of his house, a staunch adherent of the National Church.—David M., younger brother of the historian of the Greek literature, was born in 1810,

passed advocate at the Scottish bar in 1831, was appointed sheriff of Perthshire in 1853, Solicitor-General of Scotland in 1858, Lord-Advocate in 1859, and was raised to the bench in 1865. See *The History and Descent of the House of Rowallan*. By Sir William Mure, Knight, of Rowallan, written in or prior to 1657 (Glasg. 1825), and Colonel Mure's *Selection from the Caldwell Papers* (3 vols. 1854).

Murex, a genus of *Gasteropoda* (q. v.), representing the family *Murexide*. In this family the shell has a straight, anterior canal, and a broad foot is developed. In *M.* itself a long canal is formed of the extended outer lip, and the shell is covered externally with many spines or *varices*. *M. tenuispina* is a common species, often named the 'thorny woodcock shell'; the *M. erinaceus* is the 'British woodcock.' Other species of *M.* afforded the Tyrian purple dye. *M. tribulus* is the 'Venus' comb' of the Indian Ocean, and *M. regius* is the 'royal M.'

Murexide (purpurate of ammonium), a dye of a purple rose colour, yielding various shades, formerly extensively used as a dye for wool and silk, and for printing on cotton fabrics, but now superseded by the aniline or coal-tar colours. It was first observed in 1776 by Scheele as a result of the action of nitric acid on uric acid. Guano yielded the uric acid from which *M.* was once extensively manufactured. Uric acid in nitric acid yields *alloxantin*, and this substance in contact with ammonia becomes purpurate of ammonium.

Murfreesboro, a village of Tennessee, U.S., situated in a fertile plain 32 miles S.E. of Nashville. Pop. 3502. It is historically interesting as the scene of a prolonged contest, known also as the Battle of Stone River, between the Confederates and Federals, which resulted in the final retreat of the former, after the loss of 10,000 out of an army originally 35,000 strong. The fighting lasted from December 31, 1862, to January 4, 1863.

Mur'ger, Henri, a French novelist, born at Paris, March 24, 1822, after receiving a meagre education, served as clerk to a notary (1836-38), and next as secretary to a Russian nobleman, Count Tolstoi. He wrote poems, but could find no publisher for them, and plunged presently into that life of misery and adventure which he dubbed *la vie Bohémienne*, and has described in his first and ablest production, *Scènes de la Vie de Bohème* (Par. 1845). This *M.* frequently copied, but never equalled, in his *Pays Latin* (1851), *Scènes de Campagne* (1854), *Sabot Rouge* (1860), &c. He also published *Bulades et Fantaisies* (1854) and *Nuits d'Ulver* (1861), besides several comedies, as *Bonhomme Judis* (1852), and *Le Serment d'Honneur* (1860). *M.* died at Paris, January 28, 1861. A complete edition of his works has been issued in 10 vols.

Murghab, a river of Central Asia, which rises among the Hindu Kush mountains in the N. of Afghanistan, and after a generally north-westerly course for some 400 miles, during which it receives several tributaries, it is finally lost in the sandy plains to the north of Khorassan.

Muriatic Acid. See HYDROCHLORIC ACID.

Muridae, a family of Rodents, including the mice, rats, voles and lemmings. The tail is long and sparsely covered with hair; often scaly or naked. The lower incisor teeth are narrow and pointed. The collar-bones or *clavicles* are well developed, and the hind feet have five toes; the front feet only four and a rudimentary thumb.

Murillo, Bartolomeo Esteban, a great Spanish painter, baptized at Seville, 1st January 1618, learnt the rudiments of art under his uncle, Juan del Castillo. In order to gain means for travelling to Madrid, the young painter shipped coarsely-executed Madonnas by the dozen to America, and to Madrid he went in 1643. Here Velasquez instructed him, obtained permission for him to copy in the royal collection, and introduced him to the king's personal notice. *M.* returned to Seville in 1645, an eclectic in art, now painting in the style of Rubens, now of Velasquez, now of Vandyck. In 1646 he adorned the chapel of the Franciscan convent in his native town. His life thereafter was one of successful but incessant toil. It has been usual to divide his paintings into three styles: first, his *calido* or 'warm' style, in which golden tints and great transparency prevail; second, his *frio* or 'cool'

style, marked by softer execution and a more delicate harmony of colour, chiefly clear silvery tints; third, his *vaporoso*, in which wan grey colours predominate, and the drawing is less accurate. Among *M.*'s best works are the paintings in the Franciscan convent already referred to; 'The Flight into Egypt,' 'San Leandro,' 'San Isidoro,' 'The Nativity of the Virgin,' 'The Dream,' 'The Virgin of the Conception,' 'Faith,' 'St. Peter Released from Prison by the Angel,' 'St. Elizabeth of Hungary,' 'The Immaculate Conception,' 'The Blessed Virgin.' *M.* was pre-eminently an ecclesiastical painter, but has left many finely-executed portraits. His style may be best described as a combination of the rich colouring of Rubens with the depth and transparency of Vandyck. He died at Seville, 3d April 1682. *M.* founded an academy of painting in his native city. Spain now possesses only a few of his paintings; many were carried into France, the Louvre at Paris being especially rich in his works. A *Life of M.* was translated from the Spanish by Davies (1819).

Murom, a picturesque old town in central Russia, government of Vladimir, on the river Oka, 172 miles E. by S. of Moscow. It has 18 churches, a large annual fair, and extensive trade in alabaster, cucumber seed, and haricot beans produced in its vicinity. Pop. (1870) 10,173.

Murray (aboriginal name *Goolwa*), the largest river in Australia. In the upper part of its course it is also known as the Hume (the name of its discoverer), and the Indi. During three-fourths of its length it forms the boundary between New South Wales and Victoria. See AUSTRALIA.

Murray, James Stewart, Earl of, natural son of James V. of Scotland, by Margaret, daughter of John, Lord Eiskine of Mar, was born about 1531, became in his eighth year Prior of St. Andrews, later on of Pittenweem and Macon, and in 1544 took the oath of fidelity to the Pope. In 1558 he acted as one of the Scotch Commissioners at the marriage of his half-sister with the Dauphin of France, and in 1560 waited upon her at Vitry in Champagne to negotiate concerning her return to Scotland. By this time he had adopted all the leading doctrines of the Reformation. On Queen Mary's return, he advocated toleration for her religion, and she made him chief administrator of her realms. When in 1562 he married the daughter of the powerful Earl Marischal, she created him Earl of Mar, a title which he shortly afterwards laid aside to assume the earldom of Murray. Acting independently of his counsel, Mary married Darnley, whilst *M.* supported the suit of Leicester. The assumption of kingly honour by Darnley and the Catholic reaction drove *M.* and other discontented barons to arms, but they were compelled to retreat into England before the royal army in 1565. In London, to suit Elizabeth's policy, *M.* had to declare that she never gave them countenance in this 'traitorous resistance.' On the 10th March 1566 *M.* returned to Edinburgh, and though he has been accused of complicity in the murder of Rizzio, there 'is no sufficient evidence,' says Mr. J. H. Burton, 'that he was so, and such a thing is not consistent with his steady, careful, decorous walk in life.' *M.* went to France (April 1567), and during his absence was confirmed by the Estates in all his acquisitions, and on the discovery of the casket documents was named Regent. He met the Queen's forces, after her escape from Lochleven, at Langside, May 13, 1568, and routed them. In the same year he acted as one of the Commissioners at York, with power to adjust all matters rising out of the political crisis in Scotland. Among his most effectual measures was his chastisement of the Border reivers, concerning whose obedience it is written that 'the like was never done to a king in a man's days of before.' On the 23d of Feb. 1570, whilst passing in state through Linlithgow, *M.* was shot from the window of Archbishop Hamilton. With opportunities for gratifying the highest ambition, *M.* remained a strictly simple and constitutional ruler. He was a brave, wary, honest, and serious man. See J. H. Burton's *History of Scotland* (vols. iii. iv. v.).

Murray, John, perhaps the most famous English publisher in the early part of this century, was born November 27, 1778. He succeeded his father, Lieutenant John M'Murray, in a publishing business at No. 32 Fleet Street. His first happy venture was the *Domestic Cookery Book*, of which 300,000 copies were

sold. He took a higher flight with the *Quarterly Review* in 1808, for which he secured the services of the great Tory writers of the day. In 1812, when he published the first two cantos of *Childe Harold*, he removed to Albemarle Street, whence for many years much of the literary wealth of the day came streaming forth. M. was the friend of Crabbe and Moore, Rogers and Campbell, Scott and Byron, and his back parlour was a favourite resort of wits and poets. Shrewdness, enterprise, and generosity characterised all his dealings. He died 27th June 1843, since which time the business has been conducted by his son and namesake, born in 1808. If the house of M. is not now foremost in the publication of brilliant efforts of genius, it is still in the front rank, and its catalogue comprises valuable and original works in every department of literature. Its *Hand-books of Foreign Travel* are of world-wide fame.

Murray, Lindley, a popular English grammarian, was born at Swatara in Pennsylvania, U.S., in 1745, amassed a fortune in business, and on the establishment of American Independence withdrew to England, and settled at Hildgate, near York, where he spent his time in the composition chiefly of school-books. His *English Grammar* was first published in 1795, and has since gone through innumerable editions, though now superseded by more scholarly and scientific manuals. M. died 16th February 1826.

Murri (Marri) a hill station and sanitarium established in 1851 among the spurs of the Himalayas, 7330 feet above the sea, in the district of Rawul Pindi, Punjab, British India, 39 miles N.E. of Rawul Pindi. Pop. (1868) 2,346. The census was taken in midwinter; during the summer season the number of visitors may amount to 12,000. The scenery is very beautiful, and the climate healthy, though there have been disastrous outbreaks of cholera. There are 5 hotels and a thriving brewery. In September 1857, during the Mutiny, M. was attacked unsuccessfully by the insurgent hill tribes. One of the Lawrence Memorial Asylums for the children of European soldiers is situated here, and is occupied by 70 boys and 56 girls.

Murrumbidgee, a large river in the S. of New South Wales. It rises in the Snowy Range, an offshoot of the Australian Alps, and for the greater part of its course of 1300 miles flows W. until it unites with the Murray in 34° 35' S. lat., 143° 20' E. long. The country on its banks is for the most part well adapted for pastoral purposes, except near its junction with the Lachlan, where there is a vast morass. The M. is navigable by light-draught steamers for 500 miles.

Murvie'dro (Lat. *Muri Viterbes*), a town of Spain, province of Valencia, 18 miles N.N.E. of Valencia city by rail. It occupies the site of the ancient Saguntum, has a strong castle, and the ruins of a temple of Hercules. M. was at one time a seaport, but is now four miles from the coast. Pop. about 4300.

Murzuk, the capital of Fezzan, 485 miles S.E. of Tripoli. It is an oasis of the Sahara, and forms an important trading centre to the caravans of Egypt, Tunis, Tripoli, Borun, &c. It is enclosed within mud walls, and has broad streets and well-built houses. The inhabitants, estimated in 1869 at about 3000, are cold and inhospitable; but the lower classes are industrious, and work in leather, iron, and coarse fabrics. The slave-trade is actively prosecuted, and ivory, dates, senna, zinc, &c., are staple articles of commerce.

Musa'cese, or the Banana family, is a small but beautiful and highly important natural order of Monocotyledons, composed of plants without true aerial stems, but with stem-like shoots proceeding from subterranean root-stocks, and composed of the combined sheathing leaf-stalks. The veins of the generally large leaves are parallel, proceeding in a curved manner from the midrib. The flowers are congregated on spadices, which burst through the protecting spathes. All are natives of warm and tropical countries, and furnish a large supply of food, besides yielding useful fibres. The gorgeous *Strelitzia Regina* (named in honour of Caroline, queen of George III.) belongs to this order, and in addition to it four or five other magnificent species of the genus are in cultivation. See ABACA, BANANA, PLANTAIN, and TRAVELLER'S TREE for the most valuable plants of the M.

Musæus, (1) a mythic poet, who presided over the Eleusi-

271

nian mysteries in the time of Herakles. According to one legend, he was the son of Eumolpus and Selene; to another, of Orpheus. Various poetical compositions, such as oracles, precepts, hymns, &c., were attributed to him by the ancients. (2) **M.**, a grammarian, who flourished not earlier than the 5th c. A.D., was the author of a Greek poem on the loves of Hero and Leander, which was first discovered in the 13th c., and has been translated into English among others by Marlowe, Stapylton, and Stirling.

Musäus, Johann Karl August, a German writer, born in 1735 at Jena, where he studied theology, became (1763) tutor of the pages in the court of Weimar, and in 1770 Professor at the gymnasium of that town, where he died 28th October 1787. In 1760-62 he published anonymously at Eisenach *Der Deutsche Grandison* (2d ed. *ib.* 1781), a book of telling and good-humoured satire on sentimental fiction, which soon found great favour. Eighteen years after, his *Physiognomische Reisen* (Altenberg, 1778), ridiculing the fancies of Lavater (q. v.), was so popular that M. soon cast off disguise, and in a series of *Volksmärchen der Deutschen* (Gotha, 1782-86; new ed. 1868), full of a dry, genial humour, he pleasantly opened the productive mine of popular traditional tales. M.'s other works are *Freund Heins Erscheinungen* (1785), and the posthumous *Straussfedern* (Berl. 1787), left incomplete at his death, and *Moralische Kinderklapper* (Leips. 1788). His relative Kotzebue edited (1791) a small volume of his *Nachgelassene Schriften*. According to Carlyle, 'M. ranks rather as a sound common-sense thinker than as a man of high wisdom or originality.'

Muscæ Volitan'tes, or **Myodesopia**, is the term used in medicine to denote any spectrum or visual appearance which leads the patient to think that flies or black specks are moving before him. The seeing of M. V. may arise from a mere want of sensibility in certain parts of the retina (*Myodesopia insensitiva*); but more frequently from the actual perception of objects on or in the eye (*Myodesopia sensitiva*). The former condition arises from certain diseased states of the retina, or of the choroid; and the latter from the layer of mucus and tears on the surface of the cornea; from corpuscles between the external surface of the cornea and the focal centre of the eye; or from corpuscles between the focal centre of the eye and the sensitive layer of the retina. *M. insensitiva* is a serious disease, and is always indicative of danger to vision from amaurosis; but *M. sensitiva*, although in some cases of a serious nature, varies in importance according to its cause. When M. V. shift their position in the eye, they indicate the existence of *M. sensitiva*; but when they are fixed, of *M. insensitiva*. It is sometimes difficult to ascertain accurately which condition exists, owing to the movements of the eyeball; but the nature of the affection can always be ascertained by means of the ophthalmoscope.

Mus'cardine is a disease in silkworms caused by the growth through their substance of a filamentous fungus called *Botrytis Bassiana*. The spores speedily germinate when once they find their 'host,' and the threads prey upon the caterpillar until it becomes mummified. The prevention consists in care and cleanliness. See MOULD.

Muscat' or Muscatel' (Fr. *muscat*; Lat. *muscatus*, from *muscus*, 'musk'), an esteemed variety of white or black grape, extensively grown in southern districts of France, and generally in European vineyards. The French liqueur M. wines of Rivesaltes and Frontignan have a great reputation. M. grapes are allowed to become dry and raisin-like before the juice, which is then syrupy, is expressed.

Muscat', or Omân, an independent state in the E. of Arabia, extending from Râs-Mussendom in the N.W. to Râs-el-Jîad in the S.E., a distance of some 370 miles, and forming the southern seaboard of the Gulf of Omân, at the entrance to the Persian Gulf. Estimated pop. 500,000. The coast is low-lying and fertile, yielding cotton, sugar, rice, maize, water-melons, and bananas. A broken range of barren hills runs parallel to the coast, at a distance inland of from 20 to 40 miles, culminating in Jebel Achdar, 6000 feet high, and enclosing many luxuriant valleys, where are produced abundance of coffee, figs, dates, almonds, grapes, oranges, lemons, &c. Behind the mountain ridge and on the edge of the Arabian desert are many rich oases, which are mostly inhabited by Beduins. During the present

345

century an important trade has developed between M. and Europe and America. The exports are chiefly Arabian coffee, pearls, dates, sulphur, drugs, and horses. M. is by far the most important commercial depôt in Omân, but the ports of Sur and Sohar import goods from India and the Persian Gulf independently, and as the customs duties are (1875) practically in abeyance at those places, they are absorbing a great deal of trade. The existence of Omân as an independent state dates from 751 A.D. In that year the people elected a ruler, and for nine centuries the 'Imaums' were chosen on account of their personal character. In 1507 Omân was subdued by Albuquerque, and retained by the Portuguese till 1648, when it was recovered by the Arabs. Subsequently the Imaums acquired Zanzibar, Mombas, Quiloa, and other places in E. Africa, and Bender Abbas, together with certain territories on the coast of Persia, paying for the latter a fixed tribute. The country was singularly prosperous under the Sultan Said Seid (1803-56), who left M. to his son Thuwany, and appointed his second son Majid to govern Zanzibar (q. v.). The former was murdered by his own son Selim in 1868, and Selim was supplanted by an uncle, Said Tuky, in 1870. Bender Abbas and the coast settlements have meantime reverted to Persia; but M. still retains the Bahrein Islands in the Persian Gulf—the seat of the most valuable pearl fishery in the world.—M., the capital, is situated in a fertile plain, amid gardens and plantations, and on an inlet of the sea which forms a safe and spacious harbour. It is fortified, but rather poorly built, and has a very hot climate. In 1875 the customs were farmed for 120,000 dollars, which is probably much less than the actual receipts. Pop. 60,000. See Badger's *History of the Imaums and Seyids of Omân*, from the Arabic of Sahib-ibn-Kazik (1871), and Markham's *History of Persia* (1874).

Muscatine, a city of Iowa, U.S., on the left bank of the Mississippi, 41 miles E.S.E. of Iowa city by rail. It has fifteen churches, two newspapers, a farm-implement factory, and four large saw-mills. Pop. (1870) 6718.

Muschelkalk, the *Calcaire coquiller* of the French geologists, is the name given to the Middle Trias, which occurs all over the continent of Western Europe, but is absent in England. It is composed of magnesian limestone with bands of gypsum and rock-salt at its base, and contains characteristic Triassic fossils, notably the remains of Saurian reptiles. It is intermediate to the Bunter (q. v.) and Keuper (q. v.) formations, which are represented in England by the New Red Sandstone.

Musci. See MOSSES.

Muscicapidae, a family of *Insectivora* birds, including those popularly named Flycatchers (q. v.). They are included in the *Dentirostral* group of the order. They have a bill curved above, and the sides are compressed at the tip. In the true flycatchers, the bill is broad at the base, and has bristles. The wings are long and pointed, and the outer toe is longer than the inner. In the genus *Muscicapa*, the bill is short, and the nostrils are partly hidden by plumes. The tail is even, and the third and fourth quills are the longest.

Muscidae, a family of Dipterous insects, including the common house-fly and its allies. The antennæ in the M. are three-jointed. The proboscis ends in a fleshy segment. The larvæ are footless grubs, and the chrysalis is usually enclosed in the larval skin. The abdomen consists of five segments.

Muscle and **Muscular Tissue**, the names given to the tissue found in animals, in virtue of which they can move. M. constitutes what is popularly known as the 'flesh' of animals. Anatomically it is sharply divided into two varieties, named *striped* or *striated*, and *unstriped* or *non-striated* M. T. The former constitutes the so-called *voluntary* muscles, or those which are under the command of the will. The latter forms the *involuntary* muscles, which are beyond the command of the will. The *heart's* tissue may be said to be the only exception to this rule; inasmuch as the M. T. of this organ is of *striped* nature, while its action is involuntary. A muscle consists of a mass of M. T. usually attached at either extremity to adjacent parts by *tendons*. The simplest idea of muscular action is to regard a muscle as stretched between two points, and as capable of approximating these points in virtue of the property

known as *contractility*. It is this property which constitutes the distinguishing feature of M. T. The point from which a muscle springs, and which constitutes its fixed point is named the *origin*. The moving point, or that which is approximated to the fixed point in the act of contraction, is termed the *insertion*; the fleshy part, the *belly*. The *microscopic examination* of M. shows that it can be split up into bundles of fibres, the bundles being named *fasciculi*. Each fasciculus is defined by a covering of cellular tissue, the sarcolemma, which also serves to enclose the smaller bundles of which the fasciculus is composed. These smaller bundles of fibres may again be divided until the most elementary parts of the M. T., the *primitive fasciculi*, are found. This variety of structure is more especially characteristic of the voluntary muscles. The involuntary muscles are composed of long 'fibre cells' (c), flat and spindle-shaped. These cells attain a length varying from the $\frac{1}{16}$ th to the $\frac{1}{8}$ th of an inch, and a breadth varying from the $\frac{1}{16}$ th to the $\frac{1}{8}$ th of an inch. Within each cell a long *nucleus* may be seen, while along the edge of the cell dark lines or points may also be noticed. The fibre cells unite to form the fibres of involuntary muscles. This latter variety of M. T. is found in the digestive system, forming the muscular layer of the stomach and intestines which serves to propel the contents of the alimentary tract. In the trachea or bronchi the M. T. is of the involuntary or unstriped variety; it also occurs in the ureters and urinary bladder, in the walls of blood-vessels, and in the skin. It is the contraction of the M. T. of the skin that causes the prominent appearance of the skin-papillæ—an appearance well seen on exposure to cold. Involuntary muscles are sometimes also said to be made up of *organic fibres*, from the fact that they are associated with those functions named *organic functions*—such as digestion, respiration, &c., which are common to both animals and plants as organisms.

The fibres of *voluntary* or *striped* M. T. when microscopically examined, are seen to attain a diameter of about $\frac{1}{16}$ th of an inch, their greatest length being about $1\frac{1}{2}$ inches. Each fibre is enclosed within a delicate tubular sheath already noticed, called the *sarcolemma*. When the M. T. itself is torn across, this sheath may be seen to unite the torn ends in the form of a delicate membrane. The fibres of voluntary muscles are cylindrical and somewhat prismatic in form; the number of faces or sides in a fibre depending upon the manner in which it has been compressed and surrounded by its neighbour-fibres. Each fibre derives its most prominent character and its name from the fact that fine lines or *striae* (a) may be seen to mark it in a cross or transverse fashion. Hence has arisen the name *striped* muscles. The ultimate *fibrils* (c) of the striped muscle are believed to be composed of discs or portions of a thick or firm substance alternating with discs of different density. Viewed by transmitted light under the microscope, the thick portions of the fibril (or *sarcomous elements* as they are named) appear as the dark stripes, separated by the intervening lighter elements.

This composition of a striped muscular fibre may be demonstrated by the fact that the fibre may be split transversely (d)

into plates or discs of *sarcous* kind, united by the more pellucid and thinner material. The muscular fibres of the heart, we have already seen, are involuntary, but of striped structure. The heart-fibres differ, however, from the fibres of other striped muscles in that they are of finer structure: the stripes are more delicately marked, the sarcolemma is wanting, and the fibres branch and unite with each other. Muscles are well supplied with *blood-vessels*. The minute capillaries form a network on the external surface of the sarcolemma. The *nerves* of muscles are also numerous.

M. T., it has been said, shortens itself through the possession of contractility. This property is excited in various ways, but chiefly through the medium of the nervous system. In ordinary muscular action, the nerve-force, transmitted to the muscles through the nerves, supplies the *stimulus* under which contractility is excited. But chemical substances applied to M. T. will cause contraction, and stimuli of a purely mechanical kind—as when the muscle is directly pinched or irritated—will produce the same effect. It seems to be abundantly proved that the contractility of M. T. is really a property of, and is inherent in muscles. This is proved not only by the fact that a muscle will contract after division of the nerves supplying it, but also from the consideration that contractility is exhibited by muscular fibres in which no nerves are to be found. The contractility lessens or disappears when the blood-supply of the muscle is diminished or impaired—a fact demonstrated by the absence of muscular power after the main artery in a limb has been tied. Muscles possess common sensibility to pain, heat, &c., although not to a very great degree. When a muscle contracts, Bowman believes that the constituent parts of its fibrils are pressed close together, and that the fibres become shorter, thicker, and flatter, but without changing their axis or direction. The shortening of the fibre is in fact compensated for by its increased thickness. As a result of muscular contraction, *heat* is developed. Increase of temperature can be demonstrated to occur during the action of a muscle, while *sound* is also evolved. Contraction of M. does not follow after stimulation at an equal rate in all muscles. The striped muscles respond to stimulation more quickly than the unstriped; and of the latter the M. T. of the ureters and gall-bladder appears to be the least sensitive to stimuli. After death, the contractility of M. disappears first in the left ventricle of the heart; then in the digestive canal; next in the right ventricle, iris, and urinary bladder; then in the trunk and upper and lower extremities; and last of all in the right and left auricles of the heart.

The condition known as *rigor mortis*, or *post-mortem rigidity*, occurring after death, and known popularly as the 'death-stiffening,' depend upon the fact that after they have lost their contractility the muscles of the dead body pass into a state of contraction, which persists for a longer or shorter period. The muscles of the neck and lower jaw are the first to become rigid after death; then follows stiffening of the upper limbs, the lower limbs becoming rigid last of all. Rigidity varies in the period of its appearance after death. The occurrence during life of anything which causes muscular exhaustion, tends to ensure the speedy appearance of rigidity. Bedridden persons soon become rigid after death from this cause; and the reverse obtains in cases of sudden death. The rigidity endures in proportion to the tardiness of its appearance.

The disposition of the muscles in the body varies greatly in different parts of the frame. The muscles of the limbs are arranged in groups around the bones, and are applied to the performance of definite movements. The muscles of the trunk serve to enclose cavities, or to form the walls of the body; while some (e.g., the *Diaphragm*) perform an important share in the maintenance of the bodily functions.

In the movements of the body, the action of all three kinds of *levers* are well illustrated. The lever of the first order, in which the fulcrum (*F*) is between the power (*P*) and weight (*W*), is illustrated by the balancing of the head on the spine. When the head is drawn backwards, the spine = *F*; the muscles of the back of the neck = *P*; and the face and front part of the head = *W*. In the second variety of lever, the *W* is situated between the *F* and *P*. When the heel is raised, the toes being firmly placed on the ground, the *W* is represented by the weight of the body transmitted through the leg; the *P* resides in the muscles of the heel, and the *F* is represented by the toes. The third kind of lever has the *P* between the *F* and *W*. When the

fore-arm rests on a table, and a weight in the hand is approximated to the shoulder, this action is illustrated. The *F* is the fixed elbow; the *W* is the hand and its contained object; and the *P* is applied in the fore-arm, at the insertion of the *biceps* muscle.

Diseases of the Muscles.—Muscles are liable to rupture from injury, from over-exertion, and from spasms, the usual seat of rupture being at the junction of the muscle and tendon, or in the centre of the muscular belly. A rupture, if recent, is indicated by the hollow which replaces the natural outline of the muscle. Inflammation of muscles occurs usually in the course of rheumatism or syphilis. The *gummatous* tumours of the secondary or tertiary stages of constitutional syphilis appear in large muscular masses, forming round, hard, movable tumours, chiefly seen in the gastrocnemius or the scapular muscles. They show very little tendency to suppurate. Muscles are liable to *granular degeneration*, causing paralysis; and, in such cases, they are wasted away, sometimes even to annihilation. The degree of change into fat is various—in some cases no fat is found; in others it is abundant, probably as an after-degeneration. Between the striae there may be grey molecules, or the striae may be replaced by long cylinders. The muscles are frequently the seat of parasites, such as the *Trichina* (q. v.), &c.

Muses, The, were in the earliest times the inspiring goddesses of song, and were commonly held to be the daughters of Zeus and Mnemosyne, born in Pieria, at the foot of Mount Olympus. They were originally three in number, and Hesiod is the first to state the names of the nine who became established throughout Greece—viz., *Clio*, *Euterpe*, *Thalia*, *Melpomene*, *Terpsichore*, *Erato*, *Polyhymnia*, *Urania*, and *Calliope*. In later times the M. were regarded as divinities, exercising a special patronage over the various kinds of poetry, and over the sciences and the fine arts. The invocations addressed to them in this connection gradually became among classical writers as formal as they are in modern times. The worship of the M. was introduced from Thrace and Pieria into Ilerotia, when it was associated with Mount Helicon, and the sacred fountains Aganippe and Hippocrene, from whence it spread into the remoter parts of Greece. The sacrifices made to them consisted of libations of water or milk, and of honey. The poets apply to them various surnames, as *Pierides*, *Aonides*, *Aonia pullla*, derived from the localities held sacred to them, or in which their worship prevailed.

Museum primarily indicated a building devoted to the worship of the Muses; but in modern times the term means a public institution containing collections of objects, illustrating the various branches of science, especially natural history and ethnology, arts, manufactures, and industry. In Continental cities a M. also includes galleries of art, many of the most important Continental museums being devoted entirely to the exhibition of works of art. Museums may be classified into strictly scientific collections, which are used only for purposes of systematic instruction or of research; and popular collections, the main purpose of which is to communicate general instruction in an agreeable place of resort. Some museums are restricted in their scope to a limited range of objects—as, for example, zoology, botany, or geology; others are universal in their range, and embrace all departments of science, art, and literature. In Great Britain

museums of considerable importance have hitherto been almost entirely restricted to the metropolitan towns, but now the value of such institutions is being recognised in all great centres of population, and the want is being rapidly supplied. Our greatest national institution of this kind is fully described under the head BRITISH M. The South Kensington M. of the Science and Art Department, devoted principally to the illustration of art as applied to manufactures, has attained great success as a popular institution, and it has had a most marked influence on the taste of the public and the artistic skill of our artisans.

Mush'room, or Agaric, one of the largest and most important of the genera of *Fungi*, is known botanically as *Agaricus*.

Agaricus campestris (Common Mushroom).

Frequently, however, the name is limited to the one or few species popularly recognised as edible (all others being ignorantly called 'Toadstools'), while formerly among herbalists the name *A.* embraced numerous species in addition to those now included in the genus above mentioned. *Agaricus* stands at the head of the *Hymenomycetes*, the highest of the six great divisions of *Fungi*, containing those having naked spores borne on an exposed fructifying surface (*hymenium*). The common *M.* will serve as an example. Upon an underground mass of living matted cells (*spawn*

or *mycelium*), under the influence of warmth and moisture, the young *M.* is developed—at first enclosed in a tough membrane or wrapper (*volva*): in the process of growth the *volva* is ruptured, a stem manifests itself, bearing at its summit an umbrella-like cap (*pileus*), growing perpendicularly from which in a radiating manner are a number of lamellæ or plates (*gills*). The exposed surface of the gill is the fruiting, spore-bearing, or hymenial surface, certain of the cells of which it is composed (*basidia*) bearing the clusters of the four spores characteristic of the *M.* tribe. It should be noted that during the early stage of growth the *pileus* is attached to the stem by a membrane (*veil*), which on rupturing leaves a portion as a ring round the stem (*annulus*). The mature spores readily germinate, forming a *mycelium*, which in its turn continues reproduction. From the colour of the spores—white, brown, pink, purple, and black—five natural divisions for classification have been established, the total species numbering upwards of 1000, of which over 450 are British. Among those of most interest or use, the following may be enumerated. Fly *M.* (*A. muscarius*), viscid, with a warted orange or scarlet *pileus*, and having a yellowish flesh, found in woods in autumn. It is highly narcotic, producing intoxication, delirium, and death. Parasol *M.* (*A. procureus*), *pileus* 3-7 in. broad; cuticle velvety, red brown; gills very remote; common in pastures; esculent, with a pleasant taste and smell. Horse *M.* (*A. arvensis*), *pileus* 4-18 in. broad; white, very thick, firm, and tough; distinguished from the next by the almost white gills (when young), and the yellow stains of the flesh when bruised; found in meadows, often forming large rings; doubtfully esculent, but good for ketchup. Common *M.* (*A. campestris*), with its several varieties, the favourite British esculent, but said to acquire deleterious properties in Italy; the gills are at first of a beautiful pink, becoming dark with age; found in pastures, &c., and common in cultivation. In other genera of the order *Agaricini* may be mentioned as edible species the Fairy-ring Champignon or Scotch Bonnets (*Marasmius oryzae*), common in exposed pastures, and the Chantarelle (*Cantharellus cibarius*), common in woods; of an egg-yellow colour, with a smell like an apricot. A European species (*A. Easarius*) occurring in the middle and S. of Europe, in spruce forests, has long been famed on the Continent as a highly delicious *M.* As to distinguishing poisonous fungi from the edible or harmless species, no precise characters can be given, but as a general rule those that have a disagreeable smell should be rejected; also those of a lurid colour, and those that when tasted

leave a burning sensation in the mouth. In case of accident a strong mustard emetic should be administered, and medical advice obtained. In cultivating *M.* a good bed of half-dried droppings of highly-fed horses to form the bed, good spawn, and a gentle, moist atmosphere are the principal things required.

Mu'sic, one of the most delightful of the arts, is produced by a skilful combination of agreeable sounds. As some people are colour blind, others are so constituted that music affords them no pleasure. But it has a potent influence over the great majority of mankind; and the higher the state of civilisation that influence becomes purer and more refined. *M.* is in truth one of the most glorious of gifts. Even by itself it exerts a wonderful influence upon the emotional part of our being, inspiring kindred feelings within us according as its character is sublime, mirthful, passionate, or plaintive; wedded to poetry it appeals with double force to the intellect and heart. The troubadour has pressed it into the service of love, the warrior has sounded on it the note to battle, the priest has made it the medium of his praises to the Most High. The ecstasy of joy unconsciously breaks forth into singing, as the Israelites sang on their deliverance from Pharaoh; sadness is soothed by sympathetic melody, even as the sweet harp of David drove the evil spirit out of Saul. The character of peoples can often be traced in their national music. Racy of the soil are the deep sentiment of German Volkslieder, the ornate beauty of Italian arias, the light-hearted gaiety of French chansons, the homely ballads of England, the patriotic songs of Scotland, and the changeful—now gloomy, now sprightly—melodies of Ireland. And each great composer has his own secret and his own charm. The enthralling splendour of Mozart carries us into the furthest regions of phantasy and fairyland, while the gate of Heaven itself seems to open in the mighty magnificence of Beethoven and the majestic strains of Bach and Handel.

Theoretical music deals with the nature of sounds, their ratio, and relations, and with the science of acoustics. Practical music embraces the art of composition, and its performance, vocal and instrumental. In the brief space at our disposal, we can do no more than touch on a few of the leading points in each of these departments. Additional information may be gleaned under various headings in the work, but we must refer those who desire anything like a comprehensive knowledge of this vast subject to the list of authorities appended to this article.

Sounds are produced by vibrations of the air, and when these are regular and rapid they become musical. The pitch of a sound depends upon the rapidity of vibrations; the swifter the vibrations, the higher the pitch. Thus the deepest really musical sound gives about 40 vibrations in the second, the highest about 5000 in the same time (D of the piccolo flute, 4752 vibrations). Within these limits rather less than seven octaves are comprised, which may be considered the extent of sound available for the purposes of the art. An octave represents the space between any given note, and the note which produces in the same time exactly twice its number of vibrations. Thus the note called middle C in the pianoforte (although in France it has 522 and in England and Germany 528 vibrations) is usually assumed to give 512 vibrations in the second. The C an octave higher will consequently give 1024 vibrations, and if the notes be struck together the sounds will be in unison, the interval between them including all the notes in the musical system. According to the diatonic scale in use in music there are seven distinct steps of pitch in the octave, all of which bear distinct ratios to the key or primary note as follows:—

Name of note in key	C	D	E	F	G	A	B	C
of C major,	Do	Re	Mi	Fa	Sol	La	Si	Do
Ratio to key-note, I	1	$\frac{9}{8}$	$\frac{5}{4}$	$\frac{4}{3}$	$\frac{3}{2}$	$\frac{5}{3}$	$\frac{7}{4}$	2

These notes form a 'gamut,' and a higher or lower gamut is produced by simply doubling or halving the number of vibrations.

The simpler the ratio, the greater the harmony; the more complex the ratio, the greater the discord. When musical sounds are produced by stretched strings of equal weight and tension, a string half the length of another will give twice the number of vibrations, and thus sound an octave higher. And the ratios given above will apply *reciprocally* to the length of strings producing the respective notes.

Musical compositions are expressed by notes on five horizontal lines called a staff, which notes take their names according to the key or 'clef' used. In pianoforte *M.* there are two

clefs, the treble or G clef and the bass or F clef. In some musical scores, principally Italian, another clef, that of C, is used for tenor and alto parts. Tenor clef. Alto clef.

Higher or lower notes necessary in a piece of music are placed on what are called ledger lines, being supplementary lines placed where required above or below the staff. The following is the musical scale for all ordinary ranges of the human voice :—

the most usual range of voice being from lower G to upper F, as marked thus X. A sharp (#) placed before a note raises it a semitone, a flat (b) lowers it to the same extent. The alteration is increased to two semitones by the prefix of a double sharp (X) or double flat (bb). A sharp or flat placed at the beginning of a staff affects every note in the line. A natural (n) restores a note which has been raised by a sharp or lowered by a flat to its normal state. The notes C D E, &c., on the pianoforte and organ are given by the white keys, while the sharps and flats are supplied by the black keys. In the key of C Major, that is the scale with C for its initial note, no black keys are necessary. All the other major gamuts are modelled on the primitive gamut of C, and are formed by the natural notes modified by the insertion of sharps or flats when necessary to produce the major musical progression. In the key of G, for example, one note (F) requires to be sharpened; in the key of F one note (B) is flattened. Beneath are the signatures of the different major keys :—

In a diatonic scale, the various notes proceed from the key-note to its octave by five tones and two semitones. A tone signifies the distance between two sounds which have only one sound between them; a semitone is the smallest interval recognised in music. In the following major scale the semitones are indicated by slurs :—

Numbering these notes, they take the following names :—(1) tonic, (2) supertonic, (3) mediant, (4) subdominant, (5) dominant, (6) submediant, (7) subtonic or leading note, (8) final note. The tonic, the subdominant, and the dominant are the emphatic or governing notes of the scale. The first four and last four notes of the scale form two 'tetrachords,' each consisting of two tones and one semitone. Another series of diatonic scales are the minor mode, which differ from the major mode by the introduction of a minor instead of a major third. In the ascending scale the 7th requires to be sharpened, and the 6th is usually sharpened also, to avoid harshness. This is not done in the descending scale.

SCALE OF C MINOR.

Major and minor scales which have the same signatures are called relative. The following is a list thereof :—

Major Scale (in)	C	G	D	A	E	B	F#	C#	F	Bb	Eb	Ab	Db	Cb	Cb
Minor Scale (in)	A	E	B	F	C	G	D	A	D	G	C	F	Bb	Eb	Ab

Chromatic scales include thirteen notes in the octave, embellishing the diatonic scale by its semitones, and usually ascending by sharps and descending by flats. The enharmonic scale unites the ascending and descending scale of the chromatic, and includes every note to be found in the octave. An interval is the distance from any one note to another. The following are the various intervals in the octave :—

NAME OF INTERVAL.	NUMBER OF SEMITONES.	DISTANCE.
Minor Second . . .	One . . .	C to D ^b
Major Second . . .	Two . . .	C to D
Minor Third . . .	Three . . .	C to E ^b
Major Third . . .	Four . . .	C to E
Augmented Fourth . . .	Six . . .	C to F
Perfect Fourth . . .	Five . . .	C to F [#]
Imperfect Fifth . . .	Six . . .	C to G ^b
Perfect Fifth . . .	Seven . . .	C to G
Minor Sixth . . .	Eight . . .	C to A ^b
Major Sixth . . .	Nine . . .	C to A
Minor Seventh . . .	Ten . . .	C to B ^b
Major Seventh . . .	Eleven . . .	C to B
Octave . . .	Twelve . . .	C to C

A diatonic interval may be augmented by diminishing or augmenting either of the notes by one semitone. It is then called a chromatic interval.

Harmony is a combination of simultaneous sounds, each combination being called a chord. A note struck together with its 3d and 5th constitute a triad or common chord :—

The addition of a 7th to the triad gives a chord of the 7th, of a 9th a chord of the 9th, &c., &c. The triad is a consonant chord containing perfect concord, the others are all dissonant containing discords. The chord of the dominant 7th consists of a major triad and minor 7th :—

The chord of the dominant 9-7 consists of the chord of the dominant 7th with its 9th added. These chords are all subject to inversion, and also to chromatic alteration. Upon a thorough knowledge of harmony the merits and beauty of a composition greatly rest. Melody depends solely upon the imagination, harmony on the imagination combined with experience and judgment. The closing chords in a piece of music are called a cadence. When the notes in a chord rise or fall together we speak of them as proceeding in direct motion, when one rises and the other falls or vice versa we call it contrary motion. When a piece of music changes from one key to another, the alteration is described as modulation.

Musical Notation.—The following are the forms of notes in

use, each in succession being half the length in duration of the one preceding :—

Breve. Semibreve. Minim. Crotchet. Quaver. Semi-quaver. Demisemi-quaver. Semiquaver.

A number of hooked notes are grouped together thus :—

Quavers. Semiquavers. Demisemi-quavers.

A dot after a note lengthens it by one-half, a double dot by three-fourths. When silence takes place in a musical composition for a longer or shorter time it is indicated by a rest :—

Breve Rest. Semibreve Rest. Minim Rest. Crotchet Rest.

Quaver Rest. Semiquaver Rest. Demisemi-quaver Rest. Semidemisiquaver Rest.

A great number of signs are also used in M. The pause placed over a note or rest signifies that it is to be prolonged; implies repetition; a short note placed before an ordinary note (called an appoggiatura) is meant to be accented, and deprives the second note of one-half or a lesser proportion of its value. The slur signifies that the notes so marked are to run smoothly into one another. A dash | or point placed over a note directs it to be played 'staccato,' sharply and distinctly. *f* (*forte*, loudly), *mf* (*mezzo-forte*, rather loudly), *p* (*piano*, softly), *ff* (*fortissimo*) and *pp* (*pianissimo*) are directions that contain their own interpretation. *crescendo* and *diminuendo* denote a gradual increase or diminution of volume of sound. Musical terms are invariably taken from the Italian language, and are very numerous. Most works of music contain glossaries of these. *Largo*, *Adagio*, *Andante*, *Moderato*, *Allegro*, *Vivace*, and *Presto* are among the more common directions as to time, and express various degrees of rapidity in the order in which they are here written.

Rhythm is to M. what prosody is to poetry. It divides a composition into bars, phrases and sections. Bars each contain

Single bar. Double bar.

a certain and equal number of beats. At the end of a strain a double bar is placed. A composition is said to be written in common time when two or four beats are in a bar, and in triple or

ternary time when three beats are in a bar. In common time the first note and the first note in the second half of the bar are accented, in triple time the first note alone. When beats are of the value of dotted notes, the time is called compound common or compound triple time, as the case may be. The time is indicated at the commencement of a composition by a signature.

for common time
crotchet beats;

for common time
minim beats.

$\frac{2}{4}$ expressed thus : for 2 crotchets in the bar, $\frac{3}{4}$ for 3 crotchets, $\frac{4}{4}$ for 4 crotchets, $\frac{3}{8}$ for 3 quavers, and so on, the denominator of the fraction always expressing the division of the semibreve, and the numerator the number of these in the bar.

Composition.—The key to musical composition was formerly thought to be a knowledge of counterpoint, or polyphony, which is the art of part-writing, or of adding supplementary parts either above or below a musical phrase. Each added part must form a melody in itself, yet the combination must be so arranged as to secure perfect harmony. In a canon the melody repeats itself in the different parts, one portion thus forming an accompaniment to another. In a fugue the parts somewhat similarly follow in imitation. Though a freer and more imaginative

style (homophony) is substituted in modern M. for the stiff and quasi-pedantic teaching of earlier days, counterpoint is still a branch of the art which demands the attention of every composer. The earlier masters were such proficient in it that compositions containing twelve and more individual parts were common. A manuscript is said to be in existence with ninety-six parts. The writing of parts for different instruments is called 'scoring.' A thorough composer is able to write a score without hearing it, and often to judge its effect as correctly in his study as in the concert-room.

Musical compositions are of many kinds. To purely vocal M., arias, part-songs, glees, madrigals, and cantatas may be said to belong, though most of these have instrumental settings. Sacred pieces, such as masses, requiems, oratorios, *Te Deums*, and church service M. are also chiefly written for the voice, with organ or orchestral accompaniments. In opera, though the singing is of course the leading attraction, the instrumentation is of great importance, and entire sections, such as the overture, the entracte, and the ballet, are composed for the orchestra alone. Sonatas, concertos, &c., are among non-vocal compositions, and, written for one or more instruments as solos, trios, quartettes, &c., are usually termed 'chamber M.' The symphony, which is designed for a full orchestra, is the same in form as the sonata, elongated and elaborated, and consists of several (usually four) independent movements. A scherzo is a quick gay movement. A rondo, a kind of piece which rambles round again to the phrase with which it opened, is a very important movement. There are five separate rondo forms, an exhaustive treatment of which will be found in the German edition of Dr. Marx's *Theory of M.* (vol. iii.). Marches of various kinds, and old-fashioned dances like the minuet and gavotte, are favourite interludes. The crowning peroration of an entire work is termed the 'Finale.' The character of many minor pieces, nocturnes, serenades, fantasias, &c., is apparent from their titles.

Musical Instruments may be classed as (1) stringed instruments, (2) wind-instruments, and (3) instruments of percussion. (1) The pianoforte, which has superseded the clavichord, harpsichord, and other instruments of the kind, ought strictly to be called an instrument of percussion, as the notes are produced by hammer striking strings. Stringed instruments of friction include the violin (four strings), the viola (four strings tuned one-fifth below the violin), the violoncello (four strings), the double-bass (three strings, the sounds of which are an octave lower than written). In France and Germany the four-stringed double bass is much used. Double bass is sometimes tuned in fourths. On all these instruments the strings are tuned in fifths, the intermediate notes being procured by stopping the strings with the finger, thus shortening the vibrating portion. Stringed instruments, such as the harp, are called pectral, from being plucked with the fingers. The natural key of the harp is C \flat , and with the aid of pedals the pitch of the strings can be inflected one or two semitones. (2) The organ is built of wooden or metal pipes of widely different lengths, the air being supplied by a bellows, and having various sets of keys for the hands called manuals, and a set for the feet called pedals. The harmonium is another instrument with a key-board and bellows. Various kinds of flutes are used. The highest (the piccolo) plays an octave higher than the notes written. The trumpet, cornet-à-piston, oboe, clarinet, bassoon, double-bassoon, French horn, trombone, serpent, and ophicleide, are other important wind instruments. Some of these are only used in military bands. (3) Instruments of percussion include the kettle-drum, side drum, bass drum, cymbals, the triangle, &c. The usual proportion of instruments in an orchestra may be gathered from the following analysis of the orchestra of the London Philharmonic Society in 1876. Of 78 instruments, there were 13 first violins, 12 second violins, 9 violas, 10 violoncellos, 8 double basses, 2 flutes, 1 piccolo, 2 oboes, 2 clarionets, 2 bassoons, 4 horns, 2 trumpets, 3 trombones, 2 harps, and 6 drums and minor instruments. The Handel Festival Orchestra, at the Crystal Palace, numbering 447 performers, comprised 91 first violins, 90 second violins, 66 violas, 61 violoncellos, 59 double basses, 7 flutes, 6 piccolos, 7 oboes, 8 clarionets, 8 bassoons, 2 double-bassoons, 6 trumpets, 5 cornets, 12 horns, 9 trombones, 2 ophicleides, 3 double drums, 1 bass drum, and 4 side drums.

Female voices are divided into soprano, mezzo-soprano, and contralto; male voices into tenor, baritone, and bass. The

character of a voice is often not determined by range of notes, but by those which are best in quality. The following table shows the compass and relative position of the various voices :

Ordinary voices do not as a rule exceed two octaves in range, but some very extraordinary singers have had voices ranging through three and sometimes even three and a half octaves. The highest note recorded is the (C) one octave above the soprano C in the table, which on the authority of Mozart was taken by Lucrezia Ajugari. On the other hand, some very exceptional bass singers have sung the F one octave lower than the lowest in the table for male voices.

History.—M. of one kind or another has existed from the earliest times. In Asiatic countries it has made scarcely any progress for centuries, and in its present condition is probably akin to the art as known to the ancients. The Hindus at an early date developed a mathematical and scientific knowledge of acoustics. Among the ancient Egyptians certain families were set apart as musicians, and the Hebrews probably derived the art from this source. We know that the singing in the Temple was conducted by alternate choirs, and that both wind and stringed instruments were used by the Jews. M. entered heartily into their religious and national life. There has been much contention as to the acquaintance of the Greeks with the art. In the Greek drama the speeches were made in recitative, and the performers wore metallic masks to add to the resonance of the declamation. The lyre, flute, trumpet, and pandean-pipes seem to have been the chief instruments of accompaniment. The Romans cultivated M. but languidly. It had a place in their drama, and female players performed at their festivals. The early hymns of the Christian Church, borrowed from Hebrew and Pagan sources, form the basis of our modern M. Pope Gregory gave it a vast impetus by the introduction of the chants which bear his name and the formation of a school of musicians. In the 9th c. harmonies were introduced. Meanwhile national melodies sprung up, and the era of minstrels and minnesingers began. The first attempt at musical notation was made by Guido, a Benedictine monk of Arezzo, who conceived in 1022 the idea of representing notes on horizontal lines. The science and the study of counterpoint received great attention in Holland in the 14th and 15th centuries. The most celebrated of the Dutch composers, Josquin des Pres, exerted an influence all over Europe, and Palestrina in Italy, following in his footsteps, made enormous improvements in church M. Madrigals in the 16th c. became greatly in vogue in England, which could boast of such composers as Tallis, Morley, and Willbye. Italian opera seems to date from the production of Peri's *Euridice* at Florence in 1600. Among the composers of the 17th c. were Monteverde in Italy, Cambert in France, and Purcell in England. In the 18th c. M. took wondrous flights. In this century were born Handel, Bach, Haydn, Glück, Mozart, Beethoven, Marcello, Scarlatti, Porpora, Clementi, Cimarosa, Spontini, Cherubini, Rossini, and a host of illustrious composers. It were vain to attempt to follow the giant progress of the art. Church M. was perfected by Bach, the oratorio was almost created by Handel, opera under Mozart and Glück attained its highest

development, orchestral M. became beautiful under Haydn, sublime under Beethoven. Nor have the musical geniuses of our own day been few. The 19th c. can claim Mendelssohn, Weber, Meyerbeer, Auber, Schubert, Spohr, Schumann, Chopin, Bellini, Verdi, Wallace, Sterndale Bennett, and Gounod as its sons. Instrumental performance has been carried to a higher pitch than ever by great virtuosos like Paganini, Thalberg, Joachim, and Von Bülow. The art has become popular as it never was before, and inspires a hundred students for one diletante a century back. And the tide of progress in its history has not yet receded. Brahms, Raff, Rubinstein, Liszt, Gade, Rudorff, Berlioz, Massenet, Bizet, and the great Wagner himself point to a glorious 'M. of the Future.'

A list of over 500 works on M. is given in Dr. F. L. Ritter's *History of M.* (Lond. 1877).

Musical Box, a case fitted with a mechanical contrivance for playing tunes. Such boxes first came into fashion about the beginning of the 18th c., when it was common to attach small ones as pendants to watch-chains. The mechanism consists of a steel board with tongues of different sizes called a comb, a cylinder fitted with small steel points, and a fly or regulator. The notes are produced by the revolving action of the cylinder on the comb; the shorter the tongues the quicker being the vibrations, and consequently the higher the pitch. Some boxes play as many as 100 tunes. The most famous manufactories of these articles are at Geneva and St. Croix, Switzerland, at Prague, and at St. Susanne, France. Musical clocks are extensively manufactured in the Black Forest. The insertion of reeds, pipes, bells, castanets, &c., produce different kinds of boxes, such as the mandoline, organoclede, &c.

Musical Glasses, an instrument composed of glass goblets filled more or less with water, to be struck gently and rapidly with the end of a damped finger. A complete scale is formed by graduating the quantity of water, the less the quantity the lower being the pitch of the sound produced.

Music Halls, cheap-priced places of entertainment, somewhat akin to the French *Cafés Chantants*, where refreshments are supplied, and comic singing, dancing, and acrobatic exhibitions form the leading attractions. Within the last twenty years M. H. have become very numerous in England, every town containing one or more, which are largely resorted to chiefly by the working classes. The entertainments, though usually harmless, are with few exceptions of an inferior and often of a vulgar type. Some of the M. H. in London, the 'Canterbury,' for instance (opened 1876), are enormous and splendid buildings.

Musk Deer (*Moschus*), a genus of deer belonging to the family *Moschidae*, which differs from the true Deer (q. v.) or *Cervidae*, in having largely-developed upper canine teeth in the male animals, while horns are absent in both sexes. The males alone secrete 'musk,' which is contained within a glandular bag placed in the abdomen. The scent of this perfume is exceedingly powerful, and it is said that the musk-bag must be cut off at once from the animal after it has been killed, otherwise the flesh becomes impregnated and tainted with the odour. The *M. moschatus* is the common species of M. D. It occurs in N. India, and attains a height of from 2 to 2½ feet, the colour being a light brown. Another species is the pigmy M. D., or Kanchil of Java (*Tragulus pygmaeus*), which is distinguished by the black stripe running across the chest, and by its smaller size. This animal is exceedingly wary and cunning, and counterfeits death to escape the toils of the hunter. In the M. D. the blood-corpuscles are exceedingly minute, and much smaller than those of any other mammal. When extracted from the musk-gland, musk is in the form of brownish granules or pellets, somewhat greasy to the touch.

About 190 grains are found on an average in each sac. In commerce two forms of musk are distinguished—Tonquin or Thibet musk, worth £3, 10s. per oz. in the grain, and the Siberian or Russian variety, worth about 15s. per oz. The former is thus much the more valuable of the two kinds, and is imported in oblique boxes lined with lead; the musk bags, each separately rolled in Chinese paper of red or blue colour, being placed in these boxes. About 10,000 oz. are annually imported into Britain.

Musk Duck (*Cairina moschata*), a species of Duck (q. v.) found on the Central American coasts, and receiving its name from its musky odour. It is common in Guiana in winter, is of a glossy black colour, with white wing-coverts, and attains a larger size than the common duck. The hinder toe is elevated, and the base of the bill has a tubercle, while the head in the male is crested. A species of duck also named the M. D. occurs in Australia, and belongs to the genus *Biziura*.

Musket (Ger. *musquete*, Fr. *mousquet*, from Med. Lat. *muschella*, a warlike engine for throwing bolts, derived from the name of the male young of the sparrow-hawk, it being customary in the middle ages to name projectile machines after different species of hawks), a firearm introduced early in the 16th c., and carried by European foot-soldiers called musketeers. It was distinguished from the Arquebus (q. v.) merely by its larger calibre and by its great weight, necessitating the use of a rest or staff with a forked head. Gustavus Adolphus reduced the weight of the M. from 15 lbs. to 10 lbs., and thereby dispensed with the support. In the end of the 17th c. the flint-lock M. (Fr. *fusil*) became the approved weapon for infantry. This firearm was improved by the invention of the percussion lock early in the present century, and eventually was superseded by the Rifle (q. v.). Most if not all European nations have schools of musketry. The English school at Hythe is superintended by a commandant and inspector-general of musketry instruction, with subordinate instructors. The inspector-general exercises a supervision over every regiment in the service.

Musketoön, a disused small kind of musket with a wide trumpet-shaped mouth like the blunderbuss, called in France *mousquet tonnerre*.

Musk Ox (*Ovibos moschatus*), a genus of *Bovidae* or oxen found in the Arctic regions and in the extreme N. of the New World, and distinguished by their peculiarly-shaped horns,

which are about 2 feet long, and are broad and united at the base, thus forming a kind of bony shield on the forehead. The horns curve downwards and then upwards in the male; in the female they are set widely apart on the head, and simply curved. The muzzle is hairy, and the woolly hair is extremely long and of dark-brown colour. The flesh is strongly impregnated with a musky odour. The M. O. is active in habits, and lives in precipitous localities. It is considered by some authorities to exhibit a structure intermediate between the sheep and the ox, is gregarious in habits, and feeds on mosses and lichens.

Musk Plant, Musk Root, Musk Tree, Musk Wood, are names given to various plants from their musk-like odour. For the first see *MIMULUS*. The second is generally termed *sumbul root*, and though long known to trade and used in medicine for nervous diseases, it was only in 1869 that M. Kauffman discovered it to be the root of an umbelliferous plant collected by him in Russian Turkestan, to which he gave the name of *Euryangium sumbul*. It has a very powerful odour of musk, and a bitterish acid taste. The third—an old greenhouse favourite for the pleasant smell of its leaves—is the *Aster argophylla*, a native of Tasmania. The fourth is a Jamaica tree (*Guarea Swartzii*) of about 20 feet in height belonging to *Meliaceæ*. All parts, especially the bark, have a strong smell of musk, and probably the tree is possessed of medicinal properties. Other

plants might be brought into the present category, for it is well known that Oriental physicians use a number of vegetable substances with this powerful odour in their various compounds.

Musk-Rat. Under this name several very different quadrupeds are included. (1) The *Musquash* or M.-R. of N. America is described in the article *Musquash*. (2) The *Dæsmian* or *Desman* (*Galemys Pyrenaica*) belongs to the *Insectivora* (q. v.), and is also known by the name of M.-R., from the musky odour it exhales. This animal is found in the Pyrenees. An allied species, the Russian *Dæsmian* (*G. moschata*), is common in the Volga and other rivers of S. Russia. The *Dæsmians* have a long muzzle, ending in a slender proboscis. Their feet are webbed, and have five toes each. The tail is long, and sparsely covered with hair. There are no canine teeth; but two upper and four lower incisors, the molars numbering eight above, and six below. These animals closely resemble the water-shrews in appearance and habits. The Russian species attains a length of 17 inches, and is brown above and white below, the fur being highly esteemed. The French or Pyrenean species is much smaller, its tail tapers, and its colour is reddish-brown above and greyish-white below. The musky odour proceeds from certain glands placed near the tail. The animals feed on the crustaceous worms, &c., which they obtain in rivers and lakes. (3) The Indian M.-R. (*Sorex murinus*), or 'Sondell,' is a true shrew (*Insectivora*). It exudes an odour from musk-glands, so strong that it is even said to be capable of impregnating wine through the cork which it has touched. It is of a reddish-chestnut hue above, and grey on the under parts. The muzzle, as in the shrews, is pointed. The average size is that of a large rat.

Muslin, a fine cotton fabric, used plain, dyed, or printed, for ladies' dresses, or figured or embroidered for curtains and furniture coverings. M. derives its name from the Asiatic town, Mosul, where manufactories of cotton stuffs of great lightness and beauty formerly existed. Two thousand years ago Bengal was celebrated for cotton fabrics of exceeding thinness, and Dacca in that province still excels in the production of the finest muslins. England sends out to all parts of the world muslins of great variety; and in France, figured and embroidered muslins are a speciality of Tarare and St. Quentin.

Musquash (*Fiber Zibethicus*), a species of *Rodentia* (q. v.), also known as the *Ondatra* and as the 'Musk Rat.' It belongs to the *Castoridae* or Beaver family, and is found in N. America above the 20th degree of latitude. It attains a length of two feet; its colour being a dark-brown above, and ashen-grey below. The incisor teeth are white and very prominent. The M. inhabits burrows which it excavates in the banks of rivers, but occasionally builds 'lodges' or habitations like the beaver. It is hunted for the sake of the fur. Its food consists of crustaceans and molluscs, but the M. has been known to feed on vegetable matters and to devastate gardens. The hinder feet are webbed, and the animal swims and dives with great facility. It is doubtful whether the M. exhales a musky odour.

Mussel, a name given to various *Lamellibranchiate* (q. v.) Molluscs, belonging to different families. Thus the Freshwater Mussel (q. v.) belongs to the family *Unionidae*. The marine mussels are included in the *Mytilidae*, in which the shell is equivalve, and the hinge toothless. The impression of the anterior adductor muscle of the shell is small, that of the posterior adductor large. The 'foot' of the mussel secretes a byssus or 'beard,' by means of which it attaches itself to fixed objects; it is cylindrical in shape, and grooved. The halves or lobes of the mantle are united between the apertures by means of which water is inhaled or exhaled. The common M. is the *Mytilus edulis*, abundant on the British coasts, and largely used for bait by fishermen. It occupies the crevices of rocks and stones, and is found adhering in immense numbers to wooden poles immersed in the sea. Mussels are regularly 'farmed' in France like oysters. The horse M. of the sea belongs to the genus *Modiola*, and is larger than the common species; while a species allied to the latter is the Magellanic M. (*M. Magellanicus*). Mussels are a favourite article of food among the lower classes. They may be safely eaten if obtained from pure water, and from coasts on which no sewage-contamination is allowed to escape. Cases are on record in which serious illness has resulted from eating mussels taken from docks and harbours.

Probably the nature of the food on which such molluscs feed is the cause of their poisonous properties. The pearl *M.* belongs to a different family from the common *M.*

Musselburgh, a small seaport town of Scotland, in Midlothian, stands 6 miles E. of Edinburgh by rail, at the mouth of the Esk, which divides it from the suburb of Fisherrow. Its chief objects of interest are a Roman bridge, the tolbooth (1590), Pinkie House, and a monument to D. M. Moir (q. v.), a native of the place; while fishing, brewing, tanning, and manufactures of nets, sailcloth, starch, and oilcake form the leading industries. The Edinburgh races are held three times a year on the M. golf-links. As one of the Leith Burghs, M. joins in returning one member to Parliament. Pop., with Fisherrow and Westpans (1871), 4999.

Musset, Louis Charles Alfred de, the descendant of an ancient Vendomois family, was born at Paris, 11th November 1810, and educated at the Collège Henri IV., where he formed a friendship with the Orleans princes, and carried off the prize of philosophy (1827). His earliest poetical efforts—an elegy (1828), ballad, and drama—exist only in fragments. These bear a strong Romantic impress, and were indeed suggested by a visit to Victor Hugo. His next masters, Shakespeare, Byron, and Richardson, exercised no apparent influence on *Les Contes d'Espagne et d'Italie* (1830), a bizarre, sensuous work, whose mingled passion and mockery, native elegance and studied triviality, ensured its success. The Revolution of 1830 dispersed M.'s comrades of the 'Cénacle,' and thenceforward began that life which was one long suicide, its central episode the visit to Italy (1833-34) in company with George Sand, depicted by that writer in her *Elle et Lui*, and by the poet's brother in *Lui et Elle* (1859). By Louis-Philippe M. was appointed librarian to the Ministry of the Interior, a post which, taken from him in 1848, was restored under the Empire; and in 1852 he was admitted to the French Academy. He died of heart-disease at Paris, May 1, 1857. The *Œuvres Complètes* of M. (10 vols. 1865) include the *Spectacle dans un Fauteuil* (1832); *Les Nuits* (1835-37), in which, says Sainte-Beuve, his lyric talent reaches its loftiest elevation; *Lettre à Lamartine* (1836); the famous retort to Becker's *Rheinlied*—*Nous l'avons eu votre Rhin Allemand* (1840); *Namouna* (1832), a prose romance of the Don Juan type; and a series of comedies, of which *La Nuit Venitienne* was condemned at the Odéon (1st December 1830), and *Le Chandelier*, prohibited after forty representations (1847). Many of these appeared originally in the *Revue des Deux Mondes*, and all are marked by that contest of a twofold nature, seeing the good but following evil, by that blending of cynicism with enthusiasm, of child-like naïveté with blasé heartlessness, of melancholy with wild abandonment, which have endeared M., above all his brethren, as the typical and national poet of the France of the 19th c., to the present generation of Frenchmen. Wanting the wit of Heine and the sublimity of Byron, he is yet far nobler than the German, more tender than the English poet. See the *Biographie de A. de M.* (Par. 1877), an elaborate *pièce justificative* by his brother, Paul de M.; and the soberer *A. de M.* (Berl. 1877) of Paul Lindau. The most recent edition of his *Œuvres Complètes* was published by Charpentier (Par. 1876).

Mussou'ree, a hill station and sanitarium, in the district of Dehra Dûn, N.W. Provinces, British India, 6282 feet above the sea, and 1058 miles N.W. of Calcutta. Pop. (1872) 2445, but in the season about 8000. In the hot weather M. is crowded with Europeans, who have established churches, schools, hotels, clubs, and banks. Beer, also, is largely brewed. The railway station is Rârkee, from whence there is a good road. M. was a refuge for non-combatants during the Mutiny of 1857. It has recently obtained a bad reputation for gambling.

Musulman (Arab. *moslemâna*, pl. of *moslem*), a Mohammedan. The English plural is *Muslimans*. See ISLAM.

Mus'tang. See HORSE.

Mus'tard, a word of doubtful derivation, but accepted as the common name for the genus *Sinapis*, to which the plants belong that supply the condiment so generally used. The species are herbaceous plants, found in most quarters of the globe, but especially in the Mediterranean region. *Sinapis* is now, however, reduced by some botanists to a section of *Brassica*. The Black M. (*S. nigra*), widespread in the eastern hemisphere, and

probably a native near the coast in Britain, is a tall, rigid, branched annual, with bright yellow flowers, succeeded by tortuose pods of about half an inch in length, containing seeds of a reddish-brown colour. These furnish the bulk of the M. of trade, causing the plant to be largely cultivated in Durham, Yorkshire, &c. A further supply is obtained from the white M. (*M. alba*), of like distribution to the above, and met with as a colonist in Britain from mid-Scotland southwards. It bears a hispid pod two inches in length, with a sword-shaped beak. The seeds are larger than those of the black M., and of a yellow colour externally. The seed-leaves of *S. alba* are used with those of *Lepidium sativum* to form the salading called 'M. and cress.' Charlock is another species of *Sinapis* (*S. arvensis*). An oil for burning can be obtained from it, and on the Continent the plant is used for fodder. In Britain it is simply a mischievous weed, in some parts during early summer rendering the corn-fields a sheet of yellow by its gaudy flowers. In the E., the leaves of *S. cernua* and *S. Pekinensis* are eaten, and *S. ramosa*, *S. dichotoma*, and *S. glauca* (the last two united by Dr. Hooker to *Brassica campestris*) are cultivated in India for their seeds, where also *S. juncea* is grown for its oil, which is used for burning, and for medicinal purposes. The M. of Scripture (Matt. xiii. 32) is by most supposed to be *S. nigra* (it grows to 15 feet in Palestine), and by others a species of *Salvadora*.

The condimental value of M. depends principally on a pungent volatile oil containing sulphur and nitrogen, and which is present only in the black M. seeds. This oil is not developed till the M. flour is wetted, and consequently M. ought to be prepared for use by moistening it with cold or lukewarm water, and neither hot water nor vinegar should be in the first place mixed with it. There are a considerable variety of recipes for the preparation of flavoured M. for table use, in which flavoured vinegars, spices, ketchup, &c., are employed. M. is also much employed as a stimulating poultice in colds and inflammatory disorders of the chest. For poultices, 'Rigollot's leaves,' consisting of a thin coating of M. on paper, are very convenient and elegant.

Medicinal Properties of M.—The powder of the seeds of *Sinapis nigra*, and *Sinapis alba*, is used in medicine as an emetic and rubefacient. Mustard poultice is prepared by mixing 2½ parts of mustard, 2½ of linseed meal, and 10 of boiling water. The two latter should be mixed first, and the mustard should be gradually added while constantly stirring. M. poultice is used as a counter-irritant in inflammation, neuralgic pains, and spasms. M. paper, or *Charta sinapis*, is a more elegant and convenient preparation. Before application to the skin, it should be dipped in warm water for about fifteen seconds. Compound liniment of M. is used as a stimulating liniment. Oil of M. is prepared from the seeds of black M. by distillation with water, and when applied to the skin, it produces almost instant vesication; it is contained in the compound liniment.

Mustel'idæ, the weasel-family, belonging to the *Carnivorous* order of *Mammalia* (q. v.). In this family the animals are small in size. Their bodies are long, and the legs short. They walk partly on the tips of the toes, and are hence known as *Semiplantigrade* carnivora; the truly *Plantigrade* forms, such as the bears, placing the whole sole of the foot to the ground in walking. The M. have five toes on each foot.

Musters (It. *mostre*, from Lat. *monstrare*, 'to show'), parades of officers and men for inspection, receipt of pay, or verification of the returns sent in to the Admiralty and War-Office (muster-rolls), are held weekly in the navy, and in the army on the 24th of each month.

Mute, a little utensil composed of wood, brass, &c., intended to soften or deaden the sound of certain musical instruments, such as the violin or cornet.

Mutiny (Fr. from *meute* = *émute*, 'a revolt'; *mente* = Lat. *mota* from *movere*, 'to move or stir') is a word that expresses any kind of seditious or rebellious conduct on the part of soldiers, sailors, or other public servants, but in Great Britain the *Mutiny Act* refers chiefly to the first of these. It includes the planning, investigating, or taking part in any insurrection against authority, the failing to use the means in your power to suppress it, or to give information to your superior. Under the annual Mutiny Act the sovereign may form Articles of War (q. v.) and constitute courts-martial (see COURT-MARTIAL and MARTIAL LAW), with power to try

criminals in accordance with the articles, and with the provisions of the statute. This Act was first passed in 1689, from which year it has been passed annually with some alteration in its provisions, but without change in any radical point, such as the dependence of a standing army on the consent of Parliament, and the subjection of soldiers to the civil law. It is provided that any officer or private soldier who shall excite a mutiny or join it, or knowing of it shall not give notice to the commanding officer, or who shall desert, or sleep at his post, or leave it before he is relieved, or hold correspondence with a rebel or enemy, or use violence to his superior officer, or disobey his lawful commands, shall incur the penalty of death, or such minor penalty as a court-martial may inflict. The Act, as stated, recognises the supremacy of the civil courts; and any officer or private accused of a civil offence must be delivered to the civil power. Any commanding officer refusing to deliver the accused will be cashiered (see CASHIERING).

Mutton (Fr. *mouton*, 'a sheep') is the flesh of full-grown sheep. The best M. is obtained from animals from four to five years of age, but it is seldom sheep are kept more than from two to three years. The flesh of Southdown and of blackfaced sheep is esteemed the sweetest. M. contains considerably more fat and much less nitrogenous matter than beef, but next to beef it is the most valuable and extensively used flesh-food.

Mutt'ra (*Mathurā*), the chief town of the district of the same name, N.W. Provinces, British India, on the right bank of the Jumna, 35 miles N.W. of Agra, and 97 S.E. of Delhi. Pop. (1872) 59,281. It is an ancient city, mentioned by Arrian and Pliny, and it is known to have been a religious centre in the Buddhist period. But it is most famous as the scene of the birth and adventures of Krishna, and as such it is crowded by Vishnuvite pilgrims, for whose guidance there are 1400 families of Chowbays, a sect of Brahmins. The river is lined with *ghauts* or bathing-places, built from the neighbouring quarries of sandstone. M. has twice been sacked by the Mohammedans: by Mahmud of Ghuzni in 1017, who carried off untold wealth from the golden and jewelled idols, and again by the Afghans in 1757. It was acquired by the British in 1803 from the French adventurer Perron, who had received it as a fief from Scindiah. Its trade is now very great, and its merchants are reckoned extremely wealthy. The chief buildings are the Jumma Musjid of Aurungzebe, the Observatory of the Rajput Prince, Jey Singh, now both in a ruinous state; and the residence and Jain temple of Paruckji, the former treasurer of Scindiah, reputed to be the richest banker in India.—The district of M., which is crossed by the Jumna river, and watered by the newly-opened Agra Canal, has an area of 1612 sq. miles, and a pop. (1872) of 887,689. The crops are wheat, barley, millets, pulses, and sugar-cane. It contains the hills of Goverdhun, among which lies Brindaban, the scene of the amorous youth of Krishna. See *Travels of a Hindoo*, by Baboo Bholanauth Chunder (Lond. 1860).

Mu'za (Arabic form of Hebr. *Mōsheh*, 'Moses') **Ben-Nasser** (*Abu Abd el Rahman*), a famous Arab soldier, was born at Mecca in 640. Being appointed governor of Africa by the calif Walid I., he reduced (703-9) all the country on the S. shore of the Mediterranean as far as Morocco. After this he sent into Spain his lieutenant Tarik, who quickly overran Andalusia, worsted Roderic, the Gothic king, at the river Guadalete, and took Toledo, the capital of his kingdom. The next summer M. entered Spain with 18,000 men, took Asido (now Medina Sidonia), Beja, Merida, and Saragossa, and sent his son Abd el Aziz to complete the conquest of Andalusia, he himself leading his troops into Catalonia. After the greatest success in other parts of Spain, M. was preparing to carry the war into the mountain-lands of Galicia, when an order from the calif summoned him and Tarik, who had long been rivals, to Damascus. Before their arrival Walid died, and the new calif, Suleiman, deposing both generals, fined M. in a sum equal to £80,000. The calif having caused Abd el Aziz, who had been governor of Spain in his father's absence, to be beheaded, M. soon after died of grief (718).

Mycelium. Immediately on the germination of the spore in fungi M. is developed. It is a living matted mass of cells in a resting condition, needing only suitable surroundings for vivification and renewal of the species. M. has a great tenacity

of life, and is commonly, if not always, perennial. In substance it may consist of simple filaments, loose flocculent masses, branching bundles, pellicular expansions, or compact tuberculous masses (as in *Ergot*), and may produce its 'fruit' only once or repeatedly. It is what in the mushroom is called 'spawn.' The M. of certain fungi that did not pass beyond that condition gave rise to the spurious genus *Rhizomorpha*.

Myce'næ, one of the oldest cities of Greece, situated in the N.E. of Argoli, was said to have been built by Perseus. It was celebrated as the city of Agamemnon, and in his time was at the head of Greece. It was displaced from this supremacy by Argos, after its destruction, by which in B.C. 468 it remained desolate. Its ruins, which are of great extent and remarkable interest, include the great Gate of Lions, the chief entrance of the Acropolis, and the Treasury of Atreus, the largest of five subterranean buildings, to which special attention has been recently attracted by the discoveries of Dr. Schliemann.

Myelitis (Gr. *myelos*, 'marrow') is the term employed to signify inflammation of the substance of the spinal cord. The acute inflammatory stage, or M. proper, may be followed by softening or ramollissement, by undefined suppuration, or by abscess. The most common affection, however, is the ramollissement, or serous inflammation. This disorganisation may embrace the whole substance of the cord, or only one of its columns; but the centre, or grey substance of the cord is usually more softened than that of the circumference or white surface. M. may exist in the cervical, dorsal, or lumbar portions; but it is most common in those parts which contain the greatest amount of grey substance, the lumbar and the cervical portions. The symptoms of M. are, in general, limited to the parts below the seat of the disease, but they are occasionally reflected from below upwards. The first symptom is numbness, with a sensation of coldness extending up the limb—the arm or leg. This is followed by pain in the back, aggravated by pressure on the seat of inflammation, the pain being succeeded by impaired motion and sensation of one or both limbs, followed by paraplegia, or some other form of palsy. If one side only of the cord be affected, the symptoms are confined to one side only of the body; if the anterior columns be affected the paralysis is that of muscular motion; but if the posterior columns, the more prominent symptoms are those of sensation, and when the grey substance is implicated the function of reflex action is impaired. The peculiarity of the symptoms indicates the seat and nature of the spinal lesion. The disorganisation of the substance of the cord causes paralysis, more or less extensive, according to the seat and extent of the inflammation. When the disease is situated above the origin of the phrenic nerves, death may speedily follow from paralysis of the nerves supplying the diaphragm and other muscles of respiration; but when it extends throughout the cord to the fifth pair of cervical nerves, the upper extremities and those parts which receive their nerve power from a lower level of the cord are paralysed. M. is thus dangerous to life according to the portion of the cord affected.

Mygale, a genus of *Arachnida* or Spiders having large hairy bodies, four breathing sacs, and only two pairs of *spinnerets* or silk-secreting organs. The eyes or *ocelli* are eight in number. The M. excavates holes in the earth, and closes its dwelling by means of a movable lid. Among the various species may be noticed *M. avicularia* of Surinam, which captures small birds; *M. cancerides*, or the great crab spider; *M. nidulans* of the W. Indies, which makes a trap-door to its nest; and *M. Heutsii* of America.

Myhere' (*Maikhr*), the capital of a native state of the same name, in connection with the Baghelcund Agency, Central India, 128 miles S.W. of Allahabad by rail.—The state of M. has an area of about 400 sq. miles; pop. 70,000; revenue, £8000. The title of Rajah was conferred on the chief, who belongs to the Jogi or mendicant class, in consideration of losses sustained by him from the construction of the E. Indian Railway.

Myhi Gaunta (*Mahl Kāntā*), the generic name given to a group of native states in Gujerat, India, which are subordinate to one political agency in connection with the Bombay government. They number seventy-nine altogether, of which by far the most important is Edur (q. v.), and cover a total area of 4000 sq. miles, with a pop. (1872) of 447,000. By treaty with the

British in 1812 they pay a tribute to the Guicowar of Baroda of £13,840, which is collected and guaranteed by the Imperial Government. Many reforms have lately been introduced. The inhabitants mostly belong to the wild tribe of Bheels.

Mylabris, a genus of beetles allied to the blister beetles (*Cantharis*). Some species have also blistering properties, and are used under the name of 'blister-flies' to produce vesication. *M. Cichonii*, found in India and China, and *M. Fuesslini* of S. Europe, are thus used.

My'odon (Gr. 'grinder-teeth') a genus of extinct *Edentata*, the remains of which occur in recent deposits in S. America. The M. attained a length of eleven feet. It had five upper and four lower flat-crowned molars on each side. The front feet were five-toed; the hinder feet had only four toes; and the two outer toes of the hind feet were nailless. *M. robustus* is a familiar species.

Mymensing' (*Maimansink*), the chief town of the district of the same name in Bengal, British India, on the left bank of the Biahmaputra, 160 miles N.E. of Calcutta. Pop. (1872) 8253. It is also known as Nussirabad.—The district of M., which lies between the river and the hills of Assam, has an area of 6293 sq. miles. Pop. (1872) 2,349,917. It is extremely fertile, and forms the great jute-producing tract of Bengal. The external trade is entirely carried on by river. In the year 1875-76 the registered exports were valued at £1,300,000, including £576,000 of jute and £266,000 of rice; the imports were £835,000, chiefly piece-goods, salt, sugar, spices, and timber. The chief centres of trade are Bhyrul, Bazar, and Kerimgunj. The staple food-crop is rice.

Myn'ias, erroneously for **Minyas**, the ancestral hero of the Minyans, a race of nobles in Orchomenus of Boeotia. He is said to have built the first treasury.

Myn'pooree (*Mainpuri*), the chief town of the district of the same name, N.W. Provinces, British India, on the E. Jumna Canal, 727 miles N.W. of Calcutta, and 71 E. of Agra. Pop. (1872) 21,177. During the Mutiny of 1857, the treasury was preserved by the bravery of a single officer, Lieut. de Kantzow; and the Europeans escaped safely to Agra.—The district of M., which is bounded S. by the Jumna, and also watered by the canal, has an area of 1696 sq. miles. Pop. (1872) 765,845. The crops are wheat, barley, rice, millets, pulses, and sugarcane. The exports by rail to Calcutta include wheat, raw cotton, and indigo.

Myo'pia is the term used in ophthalmic medicine to denote short-sightedness or near-sightedness. It is the opposite condition of *Presbyopia*, or long-sightedness.

Myoso'tis. See FORGET-ME-NOT.

Myr'cia, a large genus of *Myrtaceæ*, natives of the tropics of America. The fruits of *M. lanceolata* have a strong turpentine odour, and are used by the Indians for making necklaces. *M. acris* produces berries that have an aromatic smell and taste, for which reason they are utilised in the W. Indies for culinary purposes, as are also the more pungent ones forming the fruit of *M. pimentoides*.

Myriap'oda (Gr. 'myriad-footed'), a class of *Arthropoda* or higher *Annulosa* (q. v.), distinguished by the large number of legs, the possession of two antennæ or feelers, and the absence of wings; by breathing being carried on by means of *trachea* or air-tubes; and by the head alone being distinctly marked. The bodies may consist of from 10 to 200 segments. The M. as a whole present very many points of affinity to Insects (q. v.), and especially to the larval stages of some of the latter animals. Newport long ago pointed out this fact, and added that the nervous system of the M. was even more nearly related to that of the *Annelides* or worms than to that of the larval insects. The head in the M. bears two antennæ, and mandibles—provided with poison-fangs in centipedes—and there are maxillæ as in insects. The legs are disposed two to each segment of the body, but, as seen in the *millepedes*, two segments may unite, and four legs thus come to be borne on an apparently single joint. The *digestive system* includes a gullet, stomach, and intestine; there are also salivary glands and biliary tubes. The *heart* consists of a dorsal vessel,

divided into a series of chambers, the blood-current being propelled forwards, or in the direction of the head as in insects. The *breathing organs* consist of *trachea*, or air-holes opening externally by *stigmata*, and resembling in all essential points those described in insects. The *nervous axis* exists as a double cord in *Chilopoda*, of which group the Centipede (q. v.) is a familiar example, but is more usually found as a single cord. The organs of sense comprise *simple eyes* or *ocelli*, and the antennæ already mentioned. The *generative system* in the females is a long tubular ovary opening posteriorly in the centipedes, but anteriorly in the millepedes. The male organs are also tubular, but are more complicated than those of the female. The M. are divided into two orders—*Chilopoda* and *Chilognatha*.

Fossil M. first occur in the coal measures, and two genera, *Xylobius* and *Archibius*, are found associated with fossil coal-plants which they doubtless inhabited.

Myr'ica. See CANDLEBERRY and GALE.

Myristica'ceæ, a small natural order of Dicotyledons, consisting of trees with simple alternate leaves, small flowers in panicles or racemes, and a one-seeded fleshy fruit covered with an arillus. They are chiefly natives of tropical Asia, and possess aromatic and acrid properties. A red pigment made from *Pyrrosia tinagens* is used in Amboyna for staining the teeth. For the most important species see NUTMEG.

Myristic Acid ($C_{14}H_{28}O_2$) occurs as a glyceride in nutmeg, butter, and otola fat. From the latter it is obtained purest, and that most easily by saponification. It is insoluble in water and ether; but dissolves in hot alcohol, from which in cooling it crystallises in white shining laminae. It forms myristates with metals.

Myrmecoph'aga. See ANT-EATER.

Myrob'alans are the astringent fruits of *Terminalia Chebula* and *T. Bellerica*, two large Indian trees belonging to the natural order *Combretaceæ*. Those of the first are smooth and oval; those of the second obscurely five-angled, and covered with silky down. Both kinds are largely imported for tanning purposes, and for the production of a permanent black in calico printing. Emblic M. are the fruits of a euphorbiaceous tree named *Emblia officinalis*. In the East they are eaten raw, made into a sweetmeat, or pickled. The bark is used for tanning, and for dyeing black; and the seeds, fruit, and leaves are employed for various medicinal purposes.

Myrrh, an aromatic gum-resin, of which three distinct varieties are known to the trade. Its origin is still enveloped in some mystery, but it is nearly certain that it is an exudation from the bark of one or more species of *Balsamodendron*, growing as scrubby spiny trees in S.W. Arabia, and about the African coast from S. Abyssinia to Cape Guardafui. One species has been called *Balsamodendron Myrrha*. M. has been an article of commerce from the most remote period. According to Scripture, it was highly esteemed more than 3500 years ago. It was primarily valued for burning as incense in temples and public worship; but by Hippocrates it was used medicinally in several diseases. At the present day it is used in incense, and medicinally as a stimulant, aromatic, and tonic. It is also applied externally as an ingredient in dentifrices, and is considered a useful application for ulcerated gums, caries of the teeth, and similar affections.

Myrrh.

Myrsina'ceæ, a natural order of evergreen shrubs or small trees, with alternate, simple, firm, smooth, entire, or spiny leaves; flowers in lateral spikes or loose umbels, and fruit a firm hard berry. They are widely distributed, abounding in the islands of the Pacific and Indian Oceans, and extending southwards to New Zealand, and N. to the Azores. None are European. The

order is in the same alliance as the holly and jasmine families. They possess no special medicinal qualities, but many are ornamental as hothouse and greenhouse plants, such as sundry species of *Ardisia*, *Jacquinia*, and *Myrsine*.

Myrtaceæ, a large, important, and interesting order of trees or shrubs with opposite, rarely alternate leaves, which are usually smooth, and entire, bear pellucid dots, and frequently have an intra-marginal vein. The flowers vary considerably, and the fruit is either a fleshy drupe or berry, or a dry hard capsule, opening by fissures at the apex. They are distributed over all tropical countries, abound in Australia, and are doubtfully represented as European by the genus *Myrtus*. Many of the species yield an aromatic volatile oil, others furnish valuable timber, and various well-known fruits and spices are the produce of the order. See ALLSPICE, BRAZIL-NUTS, CLOVES, EUCALYPTUS, EUGENIA, GUAVA, LECYTHIDACEÆ, MYRTLE, POMEGRANATE, &c.

Myrtle (*Myrtus*) the typical genus of *Myrtaceæ*, principally distinguished from its allies by its kidney-shaped seeds being enclosed in a two or three-celled berry crowned with the calyx lobes. The species are widely scattered. It is doubtful whether the common *M. (M. communis)*—so well known by its shining evergreen leaves, and scented white flowers, and by the frequent reference to it in ancient and modern writings—is really indigenous in Europe. At any rate it is now thoroughly established, and even in the S. of England it well protected is sufficiently hardy to stand the climate. The dense and knotty wood is esteemed in turnery; the aromatic, pulpy, black fruits are eaten fresh or dried as a condiment; the flowers, leaves, and a prepared oil are used in perfumery; and a Tuscan wine is manufactured from it. It is also in requisition for bridal ornament. *M. Luma*, a tree of the forests of S. Chili, grows fully 100 feet high; the wood is very hard and heavy. *M. Nummularia*, a trailing, cranberry-like plant of Fuegia, &c., produces berries of an agreeable flavour. *M. tomentosa* is a showy shrub of India and China; the dark purple berries have an aromatic sweetness. Various other species of different warm countries also yield edible fruits.

My'sis, a genus of *Crustacea* (q. v.) belonging to the order *Stomatopoda* (q. v.), and represented by species popularly named 'Opossum Shrimps,' from the fact that the females carry the young under the tail during the earlier stages of development. The eyes are stalked; and hence the name *Podophthalmate*. *M. relicta* is found in the lakes of Sweden and N. America; and another species is the *M. Chameleon* of our own coasts. *M. flexuosus* is a northern species, devoured in large numbers by salmon and other fishes.

Mysore (*Maisûrî* = buffalo town), a state in Southern India. It is surrounded on all sides by British territory, and by districts of the Madras Presidency, except on the N.W., where it is touched by the Bombay districts of Dharwar and N. Canara. It occupies the broken plateau extending from the E. to the W. Ghauts. The general elevation 2000 feet, and *drugs*, huge isolated rocks on which former chieftains placed their forts, are everywhere conspicuous. Mountains cover a large area, infested by tigers, elephants, bisons, and wild dogs, but productive of teak and sandal-wood, and now in some parts cultivated with coffee, cardamoms, and a little cinchona. The highest peaks reach a height of more than 6000 feet above the sea-level. The rivers are the Cauvery and its tributaries, and the Tunga and the Bhudra, tributaries of the Kistna. There are several beautiful waterfalls. The average annual rainfall is not much over 30 inches, though in the W. Ghauts 180 inches have been registered in the year. Irrigation, therefore, is a necessity, which was recognised of old by the Hindu rulers. It is practised from canals cut along the river valleys, and from tanks. The total number of tanks is 37,682, but many of these are in disrepair. The largest is 40 miles in circumference. The drought of 1876-77 affected M. more severely than any other part of S. India, and in Bangalore itself the mortality from actual starvation was very great. The staple crop is *ragée* (*Eleusine corocana*); other crops are rice, gram, oilseeds, coffee, sugar-cane, cotton, and the areca and cocoa-nut palms. In 1874, 111,597 acres were under coffee, of which less than one-third was owned by Europeans; the export was 2749 tons, valued at £305,000. In the same year, 43,798 acres were under cotton. There is a famous breed of cattle called the *amrit mahal*, the property of Government.

which is said to have been instituted by Hyder Ali for military uses, for which purpose it is unrivalled. Sheep also are largely bred for their wool, and a Merino cross has been introduced. The total area is 29,325 sq. miles, divided into three administrative divisions, and subdivided into eight districts. The pop. (1871) is 5,055,412, or an average of 187 to the square mile. Hindus form 96 per cent., and there are 26,000 Christians. The languages spoken are Canarese, Telugu, and Hindustani. A native force is maintained, apart from the British cantonments at Bangalore, of 2000 cavalry, called *silladars*, and 2400 infantry. The police numbers 6044 officers and men. In 1874 there were 2310 government, aided, and unaided schools, attended by 46,212 pupils. The total revenue amounts to £1,020,972 per annum, of which three-fourths come from the land, which is settled individually with the cultivators at a money rent, for a term of thirty years, according to the Bombay method. The general system of administration is similar to that of the Madras Presidency. The seat of government is Bangalore (pop. 142,513); M. town is the residence of the Rajah; and Seringapatam is the historic capital. A branch of the Madras Railway runs to Bangalore. The chief manufactures are cotton-weaving, blanket-making, brass and copper ware, and iron. Gold is supposed to exist in considerable quantities. The total exports are estimated at £1,500,000, chiefly coffee, betel nuts, rice, and cotton goods; the imports at £2,300,000, chiefly European piece-goods, salt, wheat, and silver.

The Hindu dynasty of M., which is of the Yadu caste, akin to the Rajput, and whose family name is Wodeyar, dates from about 1400. It rose to prominence in 1609, when Seringapatam became the capital, and it was overthrown by Hyder Ali in 1766, to be restored by the British after the death of Tipu Sultan in 1799. In accordance with the conditions of the treaty of 1799, Lord William Bentinck, the Governor-General of India, intervened in 1832 to restore order to the finances and peace to the country. The state has ever since been directly administered by British officials; but it has been announced that when the present Rajah, who was born in 1862, shall attain the age of eighteen years, the government will be conditionally intrusted to him. The European officers of the administration are now being gradually superseded by natives. See the *Annual Administration Reports of M.*, and the *Gazetteer of M.*, by Lewis Rice (Bangalore, 1876); Buchanan's *Journey from Madras through Mysore, Canara, and Malabar*; Wilks' *Historical Sketches*.

Mysore, capital of the preceding state, lies in a valley between two ridges, 10 miles S. of Seringapatam, has a pop. (1871) of 57,815. It was founded about 1524 as the first capital of the existing Hindu dynasty. Tipu Sultan attempted to raze it to the ground, but it was rebuilt after his death. The fort contains the palace of the Rajah, which is ornamented with wood and ivory carving. Here is an old throne, the national emblem of royalty, made of fig-wood overlaid with ivory and gold and silver. The British Residency is a large building, and the house is still pointed out where the Duke of Wellington lodged. The only manufacture is cotton-weaving.—The *district* of M., which occupies the extreme S. of the state, has an area of 4128 sq. miles; pop. (1871) 943,187. It is traversed by the Cauvery river. Wild elephants are abundant, and the breed of cattle is famous. There are special manufactures of refined sugar, leather, blankets, carts, a tannery, and works for coffee pulping.

Mystagogue (Gr. *mystês*, 'one initiated,' and *agôgos*, 'a guide'), a name borrowed from the ancient Greek religion, in which it signified one who assisted those who were being initiated into the *mysteries*, in the early Christian Church was sometimes applied to the priest or catechist who prepared Catechumens (q. v.) for baptism and confirmation. Hence *Mystagogia* was a name sometimes applied to the ceremonies and services of baptism and the eucharist.

Mysteries (Gr. *mysteria*, from *mueō*, 'I initiate'; cf. *muain*, 'to be shut') originated in that love of speaking in parables, of conveying esoteric doctrines by outward signs and ceremonies, that is common to all times and to all places, but is more especially familiar to the Eastern mind. The Eleusinian and Egyptian M., the rites of the Idæan Zeus in Crete, and of Dionysus at Thebes and Delphi, the formulæ of Rosicrucianism and Freemasonry, alike present the feature of a something hidden from

the profane vulgar, and revealed only to the initiated. What that something was it is now almost impossible to determine. Some historians have believed that the Eleusinian M. (q. v.) were local in their significance, and enshrined the elements of an older Pelagic faith, much as the Knight-Templars were suspected of Crypto-Judaism. Others, again, have sought to trace the M. of Egypt, Greece, Syria, and India to the common root of nature-worship, maintaining that the adoration of the *linga* of the Hindus—answering to the Gr. *phallos* and the Heb. *asherah* ('grove' in A. V.)—underlay the rites of Isis, Adonis, Thammuz, &c.; while the corresponding symbol of the *yon*i or *argha* ('boat') reappears, they tell us, in the myth of Argo, and consequently in the Dionysiac worship. Our knowledge of the gross licentiousness prevailing in the M. of Isis, which caused their prohibition at Rome, is certainly a confirmation of this theory. See Lecky, *History of Rationalism* (vol. ii.); Grote, *History of Greece* (part i. ch. i.); and Milman, *History of Christianity* (vol. i. ch. i.).

Mysteries, Miracle Plays, and Moralities are the names given to certain theatrical representations which were popular during the Middle Ages, and before the rise of the modern drama in Europe. Mysteries were religious dramas which dealt with cardinal events in Scripture, and especially with the mystery of the Nativity, Passion, and Resurrection of Christ; Miracle Plays set forth incidents in the lives of the saints of the Catholic Church; while Moralities or Moral Plays were dramas intended to inculcate ethical lessons by means of abstract and allegorical characters. But in many cases no sharp line can be drawn marking off the one class of plays from the others, and while in France the term *mystère* was applied to all religious dramas, in England the word *mystery*, as applied to a play, was never in use. Some have endeavoured to connect the mediæval religious plays with the classic Greek drama, to which, it has been said, they are linked by the plays ascribed to Gregory Nazianzen, in which scriptural subjects are cast into the forms adopted in Greek tragedy. But this view is probably incorrect, the true origin of Mysteries and Miracle Plays being found, in all likelihood, in the half-dramatic performance of the liturgy of the mass. Soon after Christianity had become the prevalent religion in the Roman Empire tableaux were established in churches, setting forth scriptural scenes; besides dumb show, dialogue, and lyrical interludes were afterwards introduced; and gradually genuine religious plays were elaborated—the Latin tongue, in which these dramas were at first couched, giving way to the vernaculars of the various countries in which the plays were performed, and gorgeous dresses and costly theatrical appliances superseding the simple stage accessories of earlier times. Tableaux representing scriptural events were adjuncts to public worship in the 5th c., but the earliest Mysteries proper with which we are acquainted were composed in France, and belong to about the time of the 11th c. They are in Latin. The earliest Miracle Plays of English origin are those based partly on the New Testament, partly on the legends of St. Nicholas, ascribed to Hilarius, a monk born in England about the beginning of the 12th c. Mysteries were generally written in short verses with alternate rhymes, and were not divided into acts, but into days of representation; a connected series of Mysteries or Miracle Plays being generally exhibited at the great festivals of Whitsuntide and Corpus Christi, the entire performance occupying four or sometimes even eight days. At first these plays were solely under ecclesiastical management, but afterwards they were performed by the members of the trades or guilds, and by such associations as the *Confrères de la Passion* in France. In England, the parish 'clerks' (clergy) took a large part in performing Miracle plays—*Clerkenwell* in London deriving its name from performances of religious dramas by the parish clerks of London in 1390 and 1409. Chaucer says of his clerk Absolon:—

'Sometimes to show his lightness and maistrie
He playeth Herod on a scaffold high.'

Of the various sets of plays performed by the English guilds, three great collections remain, known as the *Chester Plays*, the *Wakefield Plays*, and the *Coventry Plays*. The *Chester Plays*, twenty-four in number, were written by Ralph Higden, a monk of St. Werburgh's, Chester, and were first acted in 1327. An edition of these plays, edited by Mr. Thomas Wright, was published by the Shakespeare Society in 1843 and 1847. The *Wakefield or Towneley Plays*, thirty-two in number, were written,

it is supposed, by an Augustinian monk of Woodkirk, near Wakefield, and display a humour, liveliness, and pathos that render them superior to the other collections. An edition of these, accompanied by an excellent glossary, was issued by the Surtees Society in 1836. The *Coventry Plays*, a series of forty-two, were mainly written about 1470. An edition of them, edited by Mr. J. C. Halliwell, was published by the Shakespeare Society in 1841.

In general, Mysteries and Miracle Plays were disfigured by ribaldry and coarse buffoonery; and a purely comic interlude, styled *The Shepherd's Play*, was generally introduced between the Old Testament and the New Testament portions of the series. Miracle Plays retained popularity in England down to the 16th c., one of them being acted at Coventry in 1580. In France, on the other hand, these dramas early gave way to witty, bright, and reckless farces satirising the clergy, which were performed by lay companies or by vagrants; while in Southern Germany the old religious drama is not yet wholly extinct, a Miracle Play being represented in the present century at intervals of ten years by the peasants of Ober-Ammergau (q. v.).

The *Moralities* must not be regarded as marking a distinct stage in the growth of the drama, as connecting the English Elizabethan plays with the mediæval Mysteries. The love of allegory, which prevailed during certain epochs of the Middle Ages, found scope in the creation of these symbolical pieces, or interludes as they are frequently termed, which grew up alongside of the Mysteries and Miracle Plays, but never rivalled the popularity of the latter. Moralities first became generally known in England as a form of entertainment in the reign of Henry VI., and attained their greatest literary merit as well as their widest popularity in the reign of Henry VIII., when this form of the drama was adopted by several of the Reformers as a vehicle for satire on the abuses of the age. A salient feature of the Moralities was the part played in them by the characters styled the *Devil* and the *Vice*, the latter being a kind of demoniacal jester, whose function was to beat and flout the superior fiend for the amusement of the audience. The *Vice* is alluded to by Shakespeare as 'the old Vice,' 'the formal Vice, Iniquity,' &c. He is also alluded to in Jonson's *Staple of News*. Among the oldest existing Moralities in English are *The Castle of Perseverance*, belonging to the reign of Henry VI., which relates the siege of the *Humanum Genus*, in the Castle of Perseverance by the Seven Deadly Sins; *The World and the Child*, a play written about 1520; *Every Man*, an earnest Catholic piece produced about 1531; *Lusty Juventus*, composed by one R. Wever, in the times of Edward VI., a very interesting play reflecting the spirit of the Reformation; and John Skelton's *Magnificence*, a vigorous, lively piece distinguished by the writer's characteristic ingenuity in rhyming and wealth of racy diction. *Magnificence* was written about 1520, and is included in Dyce's edition of Skelton's works (2 vols. 1843). But the best of all the Moralities produced in England or Scotland is Sir David Lindsay's *Satire of the Three Estates*, produced in 1535. (See LINDSAY.) The Moralities survived in England until the beginning of the 17th c., though they had long before that been completely eclipsed by the rise of the true English drama. In the reign of Elizabeth they began to vary considerably in their character, real historic personages being introduced amid their allegorical figures, as, for example, in Bale's *King Johan*. The term *Morality* was applied in France to plays partly similar to their English namesakes, but in general far sprightlier, and more audaciously satiric. They give valuable glimpses of the old French society, and are farcical rather than didactic. They sometimes contain scriptural personages as well as personified qualities among their characters. They were popular during the 14th and 15th centuries, and were represented by the dramatic fraternities of the *Basoche* and the *Enfants sans souci*.

Collections of French Mysteries and Miracle Plays have been made by Monmerqué and Michel (Par. 1839) and Jubinal (Par. 1837). Mone has done the same service for Germany in his *Deutsche Schauspiele des Mittelalters* (Quedt. 1841). See Ward's *History of English Dramatic Literature* (Lond. 1875), Hazlitt's edition of Dodsley's *Select Collection of Old English Plays*, Collier's *History of English Dramatic Poetry*, Wright's *Early Mysteries and other Latin Poems* (Lond. 1838), Gidel's *Histoire de la Littérature Française* (Paris, 1875), Wilkens' *Geschichte des geistlichen Spiele in Deutschland* (Gött. 1872).

Mysticism has been defined as the Christian form of Pantheism. A *mystic* was one initiated into a knowledge of the Greek mysteries—one to whom secret things had been revealed. Hence a mystic came to mean one who claimed to know, either by intuition or by inward revelation, what was hidden from other men. And as these two methods have generally been assumed to be identical, M. includes 1. 'All those systems of philosophy which teach either the identity of God and the soul, or the immediate intuition of the Infinite.' In this sense the pantheism of the Brahmins and Buddhists, the theosophy of the Sufis, the Egyptian and many forms of the Greek philosophy, as well as the modern system of Spinozism, are all mystical. 2. Evangelical Christians, who believe in a supernatural influence of the Holy Spirit, and recognise a higher form of knowledge, holiness, and fellowship with God as the effect of the influence, are regarded as mystics by those who discard the supernatural from religion altogether. 3. The epithet of mystic has been applied to any system of philosophy or religion which, like Schleiermacher's, assigns more importance to the feelings than to the intellect. 4. M., as known in Church History, has generally been a reaction against the dogmatism of the Church. Mystics in this field have been divided into two classes: Theosophists, 'whose object is knowledge, and with whom the organ of communication with God is the reason; and Mystics proper, 'whose object is a pure and happy life, and with whom the organ of communication is the feelings.' There was a good deal of M. in the first forms of Monachism (q. v.), as well as in Montanism (q. v.). The father of thoroughgoing M., however, was the Pseudo-Dionysius (q. v.), whose writings appeared about 523. His theology, which was founded on Neo-Platonism (q. v.), had much influence on the religious thought of the Middle Ages. The originators of the later M. were those Schoolmen who endeavoured to reconcile the claims of speculative piety with those of scientific theology, and have hence been called the Dialectical Mystics. These Mediæval Mystics have been divided into three classes: I. The Mystic Scholastics, who held to the orthodoxy of the Church, e.g., Bernard of Clairvaux, Norbert, Hugo and Richard of St. Victor, &c.; II. The Heretical Mystics, e.g., Scotus Erigena (pantheistic), Eckhart, Ruysbroëk, &c.; III. The Latitudinarian Mystics, an intermediate class, e.g., Von Cölln, Tauler, Suso, Gerson, Thomas à Kempis, &c. The mystical school of writers was continued in the 16th c. by such men as Paracelsus, Weigel, Boehme, &c., and in more recent times by Swedenborg, Heinrich, Stilling, and Lavater. Special forms of M. are noticed under PIETISM and QUIETISTS. See Hodge's *Syst. Theol.* (Edinb. 1873), Hagenbach's *Lehrb. d. Dogmengesch.* (Eng. trans. 1847), Ullman's *Reformers before the Reformation* (Eng. trans. 1856), Bampton Lectures for 1824.

Mythology, Comparative. Wherever speech is uttered, tales are told—tales that, whether couched in stately epic or lowly nursery rhyme, narrated by an Andersen or in a Bushman's *krakal*, whether beautiful or grotesque, repulsive or sublime, have all one common feature—their inefable antiquity. The Arthur of Tennyson is the same Arthur from whom the everlasting hills received their names; Lafontaine's milkmaid had broken her pot in India two thousand years before; and the siege of Troy forms the subject alike of Homer's *Iliad* and of a Suffolk 'horkey ballad.' To solve the origin of these tales or myths (Gr. *mythoi*), as they are called, is the problem of the science of M. Bacon, with many of the old philosophers, read in them allegories invented by priests for the conveyance of esoteric doctrines. The Sphinx, he explains, is science; her talons, arguments and axioms; while Œdipus' lameness hints how through overhaste men fail in the solution of her riddles. The Euhemerist, or historical theory again, regarded the Centaurs as skilled horsemen, Atlas as a great astronomer, Priam as an Eastern, and Woden as a Western king. Bochart, Vossius, and Huet belonged to this school, only that they sought in classical M. for traces, not of profane, but sacred personages, identifying Saturn with Noah, Vulcan with Tubal Cain, and Typhon with Og the King of Bashan. So, too, Mr. Gladstone, its latest and ablest exponent, discovers in myths the relics of a corrupted revelation, granted by God to man before the dispersion of Babel; Zeus, Hades, and Poseidon representing the Christian Trinity, Athene and Apollo dividing the Messianic attributes, and Leto, their mother, shadowing forth the woman whose seed should bruise the serpent's head (*Homer and the Homeric Age*, and *Juvenius*

Mundi). The clue to a third system of investigation was furnished by Comparative Philology. The science that had traced a connection between the Gr. *mytē*, the Lat. *mola*, the Eng. *mill*, and the Erse *meile*, detected the identity of names in mythologies so widely remote as the Sanskrit and Celtic, the Norse and Hellenic, the Slavonic and Iranian. Dyu, Zeus, Jupiter, and Tyr, Varuna and Ouranos, Sarvara and Cerberus, Pani and Paris, Sarāmā and Helene—these and a host of other names phonetically identical, even in their accent, showed that the mythologies of the Aryan races were, like their languages, the descendants of a common stock. But as in fiction such names as Verisopht, Deuceace, or Bareacres suggest the characters of those who bear them, so does the mythic nomenclature convey to the philologist a no less pregnant meaning. One common concept—that of the powers of nature—is seen to underlie the names of gods and heroes in the *Iliad*, the *Zendavesta*, and clearest of all in the *Veda*, as there oftenest are those names used, not merely as proper names, but as appellative nouns—Ushas (Gr. *Ēōs*), Saranya (Gr. *Erinyes*), and Ahanā (Gr. *Athenē*) all signifying the 'dawn'; Marut (Lat. *Mars*), the 'storm-cloud'; Varuna (Gr. *Ouranos*), the 'sky,' and so on through a hundred other instances. How comes it, though, is the next question, that the early myths dwell on nature to the exclusion of all other subjects? Because to primeval man, set naked in an unknown world, nature was all in all. He hailed the warmth and radiance of the sun; like a child, he dreaded the horror of night's darkness, and all his emotions of hope and fear centred around the glowing disc, for which his struggling faculties of speech devised a hundred names—the Bright, the Warm, the Riser, the Setter, the Victor, and the Vanquished. In rude and early languages there is always a wealth of synonyms, some of which by a process of natural selection, either drop wholly out of use, or lingering on in a corner of the brain, give rise thereafter to countless misconceptions. Thus epithets, originally synonymous, applied by man to his vague conceptions of nature's divine phenomena, were certain to give rise to polytheism; just as the phrase *Daphnē* flies from Apollo, i.e., the dawn fades before the rising sun—first used, not as a conscious metaphor, but as the nearest expression of a visible fact—would invest Apollo, regarded as a god, with anthropomorphic attributes. A source of further error arose from the identification of words similar in sound, but of a different meaning—of *daphnē*, 'the dawn,' with *daphnē*, 'a laurel,' of the seven *rikshas* or 'bright stars,' with seven *rikshas*, or 'bears,' and later with seven *rikshis* or 'sages'; of *leukos*, 'shining,' in Lykaon 'with *lukos*, 'a wolf' (whence the were-wolf superstition); and in more recent times of *fairies* with *Pharisees*, and *barnacle* shells with *barnacle* geese. We may distinguish, therefore, four stages of myth-making—(1) The Unconscious, when man first used such phrases as 'The brilliant dawn is dead'; (2) The Polyonymous, when he might either say 'The brilliant (*daphnē*), or the seaborne (*aphrodite*), dawn is dead'; (3) The Anthropomorphic, in which 'dead' would cease to be the figurative language of childhood; and (4) The Homonymous, when *Daphnē* would be metamorphosed into a laurel. Not that these stages were ever perfectly distinct. Like the Stone, Bronze, and Iron Ages of Palæontology they overlapped one another; and the primary signification of the Aryan *dyu* survived in the phrases *Zeus hydor poiē* and *sub Jove* long after Zeus and Jupiter had taken their places in the Hellenic and Roman pantheons. Other important elements in the later development of M. were—Change of surroundings; the localisation of myths; and their poetic embellishment. That the Aryan nations went forth at their dispersion carrying with them a common M. is attested both by corresponding nomenclatures, as we have already seen, and by countless recurring episodes. For instance, Arthur's Excalibur answers to the swords of Theseus and Odin; and the Greek Achilles, the Persian Isfendiyar, and the Norse Baldur are alike invulnerable save in a single spot. But as the languages of southern differ from those of northern Europe, though sprung from the same stock, as the devil of the negro is white, and the hell of the Eskimo a region of frost and snow, so little wonder if in the Edda and Volsung Tale we recognise the warring, not of the sun with night, but of winter with summer, if spring replaces dawn, and dwarfs—not giants—are the guardians of the hidden treasure. Secondly, in numerous myths we light on mention of real places and historic personages—Troy and Caerleon, Arthur and Karl the Great. Therefore, say the Euhemer-

ists, these myths enshrine the germs of history. But is not the scene of *The Virginians* laid mainly in London, and do not General Wolfe and Dr. Johnson walk through its pages? Only when the mythologist can dis sever the true and fictitious in Thackeray's novel without a previous knowledge of English history, may he hope to do the same in the *Iliad*, the *Nibelungen*, or the *Arthurian Cycle*. Still, M. had undoubtedly been at all times deeply tinged by past and passing events, by man's fondness for patching new cloth on old, although to what extent can be shown only by external evidence. And this conducts us to our closing argument. To listen to many advocates of the solar-mythic theory, one would imagine that no incident could be historical because enshrined in a myth, or that every mythic episode was necessarily solar in its origin. A fallacy like his who should fancy that, because the first conception of a pillar was borrowed from the trunk of a tree, therefore every succeeding pillar must reproduce the bark and knots, and nothing else; or that the *Paradise Lost* of Milton contains nothing but what may be found in the Book of Genesis! Whateloy satirised the extravagances of this school in his *Napoleon a Solar Myth*, where nApoleon = Apollon, the sun-god, who rises in the eastern and sets in the western waves; but the parody falls short of reality, as contained in De Gubernatis' *Zoological M.* (2 vols. Lond. 1872) and the works of sundry of his followers. No, we cannot refuse to the poets of antiquity a power that must needs be conceded to Tennyson and Morris, of clothing a mythic skeleton in the flesh and blood of the poet's new thoughts and experiences, of adding and taking away, blending and harmonising, until his work, substantially the same as Homer's or Malory's, grows to a new creation. We have dwelt exclusively on the myths of the Aryan races, because theirs alone have been adequately investigated, and of theirs alone do we possess ancient, and therefore more typical, records. But other mythologies—

Accadian, Semitic, Turanian, and Iberian—exist or have existed; and what their character was, whether solar or otherwise, is a question affecting the Aryan M. itself. That mixed mythologies are, like mixed languages, a thing impossible, that the Persians can have borrowed nothing of the Assyrians, the Greeks of the Egyptians, or Christendom of Judaism is at least opposed to probability; and why, if the Basque folklore of to-day is purely French, should not the Celts have conversely adopted something of the M. of the conquered Iberians? A word as to what M. was not. It was never identical with religion, one whit more than Legend (q. v.) forms an essential part of the Catholic system. In Homer and Hesiod we recognise, amid all their fantastic pantheon, a one Zeus, 'omniscient and omnipotent,' who 'can do all things,' and 'fulfils the prayer that man utters' (Od. iii. 26; xiv. 444, &c.); but that the mythic Zeus, the intriguer and adulterer, swayed the Hellenic mind for good or ill is nowhere more apparent than that the legend of the Holy Grail had any influence on the doctrine of the Eucharist, or the Alsatian folk-tale of St. Peter and the Lamb's Liver upon the dogma of the Infallibility. See Max Muller, 'Comparative Mythology' in vol. ii. of *Chips from a German Workshop*, and vol. ii. of the *Science of Language*; G. Cox, *Mythology of the Aryan Nations* (2 vols. Lond. 1870); Kelly, *Indo-European Folklore*; Grimm, *Deutsche Mythologie* (Gött. 1835); Tylor, *Primitive Culture* (2 vols. 1871); Dasent, *Popular Tales from the Norse* (Edinb. 1857); Welcker, *Göttenlehre* (3 vols. Gött. 1857-62); Creuzer, *Symbolik der aller Völker* (4 vols. 1810-12); Fiske, *Myths and Mythmakers* (Lond. 1873); Sayce, *Principles of Comparative Philology* (Lond. 1874); and Goldziher, *M. among the Hebrews* (Eng. trans. Lond. 1877).

Myx'ine. See HAGFISH.

N.

the fourteenth letter in the English alphabet, corresponding to the Greek *nu* and the Semitic *nun*, is formed by the tongue at the junction line of the upper teeth and palate, and passes mainly through the nose. It is therefore a nasal liquid, and an imperfect mute. N is interchangeable with *l*, as *luncheon*, *nuncheon*; is mute after *m*, as *hymn*, and often before *v*, as *Covent* (for *Convent*) *Garden*; and is extremely liable to be improperly affixed or taken from words, as *nonce* for *once*, *adder* for *nadder*, &c. With the Romans N stood for 900, and with a stroke over it for 9000; while as an abbreviation it now usually signifies *North*. It also appears in N. B. (*nota bene*), N. S. (*new style*), &c.

Naaf, a small river or rather arm of the sea in the E. coast of the Bay of Bengal, running due S., and forming the frontier separating the Bengal district of Chittagong from that of Akyab in British Burmah.

Naas (Irish Gael. *Nás*, 'a fair,' or 'meeting place'), the second largest town in county Kildare, Ireland, on the Grand Canal, 20 miles S. W. of Dublin, and 3 S. of the railway station of Salins. It was anciently the residence of the kings of Leinster, and, according to bardic history, was founded by Lewy of the long hand. The great mound of the royal palace still remains just outside the town. See Joyce's *Irish Names of Places* (vol. i. 1869). N. received charters from Henry V., Elizabeth, and James I., but in recent times it has greatly declined, though still a municipal and assize town, with a court house, infantry barracks, a workhouse, &c. Pop. (1871) 3660.

Nabathæans. In Scripture history Nebajoth was the first-born of Ishmael (Gen. xxv. 13; 1 Chron. i. 29), and father of a tribe in Western Arabia beside the tribe of Kedar (Isaiah lx. 7). This tribe is by Josephus (*Ant.* i. 12, 4) and Jerome (Gen. *in loc.*) identified with the N. or Nabateans, who, according to these writers, gave their name to all the region from the Euphrates to the Red Sea, and who in the time of the Maccabees (about B.C. 160) occupied the same region (1 Macc. v. 25, ix. 33-37; Jos. *Ant.* xii. 8, 3). During the height of their power the country of the N. embraced the whole of Edom, from which they drove the Edomites (see *EDOM*), and the plain of Arabia between the northern half of the Red Sea and the Mountains of Nejd, being bounded on the west and north by Palestine and Bashan. Besides being rich in flocks and herds, nearly the whole commerce of Western Asia was in their hands. From their capital of Petra, the ruins of whose rock-hewn buildings yet testify to their great wealth and civilisation, caravan tracks radiated in all directions: to Palestine, Phœnicia, Damascus, Palmyra, Mesopotamia, to the ports on the Persian Gulf and the Red Sea, and to Egypt. The first mention of a king of the N. is about 166 B.C. (2 Macc. v. 8). All their kings bore the title of Aretas or Obodas, and the country was called Arabia Petraea or simply the kingdom of Arabia. Herod Antipas married a daughter of the Aretas of the time (Jos. *Ant.* xviii. 5, 1), probably the same who captured Damascus and governed it by an Ethnarch (2 Cor. xi. 32). The first blow to their prosperity was received when a new route between the east and west was opened through Egypt. The kingdom was annexed to the Roman Empire in A.D. 105, and the cities ruined by the Mohammedan conquest.

That the N. were Ishmaelites has been disputed in modern times. There is an Arab tribe, the Beni Nabat, believed by Oriental scholars to be of Aramean or Syro-Chaldean origin,

who in the time of their early prosperity inhabited Chaldea and Mesopotamia, and were celebrated for their knowledge of agriculture, magic, astronomy, medicine, and science. For numerous considerations which cannot here be given, it is believed by the best authorities that the N. are identical with this ancient nation of Nabat.

Nablus, or **Nabulus** (Gr. *Néapolis*, 'new city'), the ancient *Shechem*, and former capital of Samaria, a town of Palestine, in the valley of Erd-Mûkhna, 1½ miles W. of Jacob's Well, and 30 N. of Jerusalem. The valley, one of the richest in Palestine, produces abundance of figs, grapes, oranges, and olives, and the town has manufactures of oil, cotton, soap, &c. Pop. about 10,000, of whom 500 are Christians, 150 Samaritans, 100 Jews, and the rest Moslems. See the Rev. J. Mills, *N., a Narrative of a Three Months' Residence* (Lond. 1877).

Nabob, an English corruption of *NAWAUB* (q. v.).

Nabonassar, **Era of**, in Babylonian chronology, commences with February 26, 747 B.C. It seems to have been invented by Ptolemy, as it is not the system of the Cuneiform inscriptions, nor do its dates agree with established historic facts, such, for instance, as the destruction of Nineveh.

Nachimov, **Paul Stepanovitch**, a Russian admiral, born in 1803, in the government of Smolensk, circumnavigated the globe under Sasarev (1822-25), was present at the battle of Navarino (1827), and commanded a corvette in the blockade of the Dardanelles (1830). Appointed, on the outbreak of the Crimean War, to the command of the Russian fleet in the Black Sea, he annihilated a Turkish squadron off Sinope (November 30, 1853), and having played a gallant part in the defence of Sevastopol, was raised to the rank of Admiral (April, 1855). On the 10th July of the same year he was struck by a bullet, and died the following day.

Nach'od, a town in Bohemia, on the Mettau, near the Prussian frontier, 21 miles N.E. of Königgrätz, famous as the scene (27th June 1866) of the first of the struggles between the Prussians under Von Steinmetz and the Austrians under Ramming, which ended in the battle of Sadowa.

Nacre. See *MOTHER OF PEARL*.

Na'dir is the point of the heavens vertically below us. It is thus diametrically opposite to the Zenith (q. v.), and geometrically is one of the poles of the true horizon.

Nádír Sháh, the hero of Persian independence, and the last of the great Mohammedan invaders of India, was born near Khelat, November 11, 1688. He commenced life as a robber chief in Khorassan, but, though himself belonging to a Turcoman tribe, became the national leader of the Persians in their successful attempt to throw off the yoke of the Afghans and to recover Armenia from the Turks. At first he permitted the restoration of the old royal family, but in 1736 he had himself crowned Shah. N. extended his conquests over Georgia and Afghanistan, and in 1738 occurred his celebrated invasion of Hindustan. He sacked Delhi, and is related to have brought back with him a treasure of twenty millions sterling, including the Kohinûr diamond and the peacock throne. On his return his character is said to have changed. He became avaricious and tyrannical, and he was assassinated June 20, 1747. N.'s dynasty perished with him. His son finally became an officer in the Austrian service, and his wealth was carried off by his treasurer, Ahmed Shah Abdali, who founded the Durani dynasty in Afghanistan.

Nævius, Qn., is really the earliest of the Roman poets whose writings evince genuine power and originality. On the authority of Aulus Gellius (i. 24), who characterises his famous epitaph as 'plenum superbiæ Campanæ,' he is believed to have been a Campanian. Klussmann, one of his most careful editors, thinks he was a Roman; but the above expression could scarcely be applied to any one but a native of Campania. N. was, however, thoroughly Roman in character and sympathies. He came to Rome early, but from the uncertainty attaching to the date of his birth—some time between 274 and 264 B.C.—it is impossible to say definitely in what year. N. served in the first Punic war, which began in 264 B.C. and lasted 24 years. He produced his first play in 235 B.C. Like the writers of the old Attic comedy, he employed the stage as the arena for popular invective and political warfare. He was a keen partisan of the plebeians, and a sworn foe to the senatorian party. In addition to his dramatic works he wrote an epic poem on the first Punic War in the Saturnian metre—a work of which a few unimportant fragments remain. N. also wrote 'ludi' or 'satiræ.' These were probably the vehicle of his attacks on the aristocracy. For a lampoon on the Metelli, preserved by Asconius (see *Cic. Verr.* i. 10), he was indicted by one of the family. By the laws of the Twelve Tables a libel was a capital offence. N. escaped with his life, but was handed over to the custody of the triumviri capitales. Confinement brought the poet to a recantation of his imputations, but his repentance can hardly have been sincere, as a fresh offence had soon to be expiated by exile. N. died at Utica, his self-chosen place of banishment, in 204 B.C., according to Cicero, Varro and Hieronymus say two years later. See Klussmann's *Life and Remains of N.* (Jena, 1843); M. J. Berchem *de Cn. Nevii. Poeta Vita et Scriptis* (Münster, 1861) and Sellar's *Roman Poets of the Republic* (Edin. 1863).

Nævus, or **Erectile Tumour**, known popularly as **Mother's Mark**, consists essentially in an excessive development of the vascular tissue of a part, arterial, capillary, or venous. *Arterial N.*, commonly called *aneurism by anastomosis*, is an irregular, lobulated, pulsating tumour, into which numerous large vessels can be traced, and in which a considerable *bruit* can often be heard. The usual seat of such tumours is the scalp and lip. Small tumours may be cured by ligature, and large ones by the galvanic cautery. *Capillary N.* are slightly elevated, but flat spots on the skin of a bright red or purplish tint, entirely confined to the skin, congenital, and though at first small may attain a large size, and involve the whole of the face. *Venous N.* are usually subcutaneous; but those in which the skin and cellular tissue are affected simultaneously are usually of the mixed kind, and large veins may be seen passing away from them. The venous N. are of a dark purple or reddish colour, smooth and ovoid, or somewhat lobulated, and often of considerable size. N. may be cured (1) by exciting adhesive inflammation in them, so as to produce plugging and obliteration of the vascular tissue, as by vaccination or injection of perchloride of iron; (2) by agents that destroy the growth, as nitric acid; (3) by removal with the knife or ligature.

Näfels, a village of Switzerland, in the canton of Glarus, on the Linth, 5 miles N. of Glarus by rail. Here on the Rautfeld 1500 Swiss defeated 8000 Austrians, April 9, 1388. The battle-field is marked by eleven stones, and the people of the surrounding villages come yearly on the second Thursday of April to celebrate the anniversary of the victory which secured their independence. Pop. (1870) 2490.

Nāgarī (an adjective derived from the Sanskrit *nagara*, a town), the term applied to the character used in writing the Sanskrit alphabet, and to its modifications in Hindi, &c. It is sometimes written Devanagari (*deva*, signifying 'divine'). See **NUGUR**.

Nāga's, a wild race of Aborigines, bordering on Assam, in the N.E. frontier of British India. They are divided into many tribes, some of whom are inoffensive and trade freely with British subjects. Their exports are cotton, caoutchouc, timber, and beeswax. Other tribes are very warlike, and are notorious for their practice of carrying off as trophies the heads of their enemies. Since 1866 a British officer has been stationed in political charge of the N. tribes between the State of Munnipur and Assam, who exercises a general control but no direct

government. The area of the tract held by the N. is 4900 sq. miles; the pop. (1872) 68,918. In 1875, and again in 1876, officers were murdered who were engaged beyond the frontier on survey duties, but the prestige of the British name has now been restored.

Nagasakī, a town of Japan, on the N.W. side of the island Kiu-Siu. Its excellent harbour was the only place in Japan where, under severe restrictions, the Dutch were allowed to trade for nearly two centuries, but since 1859 N. has been freely open to foreign commerce. It is famed for its figured porcelain, which, on account of its extreme thinness is called 'eggshell china.' The imports are chiefly cottons, woollens, metals, arms, and ammunition; the exports, coal, tea, dried fish, tobacco, camphor, copper, and vegetable wax; and the total value of the former in 1875 amounted to £317,727; and of the latter to £449,855. In the same year there entered the port 296 foreign ships of 276,415 tons, and of these 120 were British ships of 67,791 tons. A great coal mine on the island of Takashima, which is under the superintendence of English engineers, employs some 3000 natives, and yields 600 tons daily of excellent coal (124,930 tons in 1875). N. is retarded much by the want of good roads leading to the surrounding tea-districts. Pop. of town, 80,000; of the Ken (1875), 668,974.

Nagelhue. See **MOLASSE**.

Nagode or **Ucheyra**, the capital of a native State of the same name, in connection with the Baghelcund Agency, Central India, 110 miles S.W. of Allahabad. The State of N. has an area of about 450 sq. miles, and a pop. of 75,000. Revenue, £15,000, of which half is alienated in feudal or religious grants. The Rajah received an accession of territory for services during the Mutiny.

Nāgpūr (*i.e.*, Snake-town), the capital of the Central Provinces, British India, and of the district of the same name, on the left bank of a stream called the Nag, 520 miles E.N.E. of Bombay by rail. Pop. (1872) 84,441. It lies in a hollow round the fort and European station of Sita-baldi. The cantonments are at Kampti (q. v.), 9 miles N.E. Outside the city are handsome tanks and gardens, constructed by the Mahattas. The streets are well laid out, and the houses are ornamented with wood carving. Conservancy arrangements are good, and the city is healthy. The palace of the Bhonslas, built of black basalt, was burned down in 1864. Tombs of the former sovereigns are numerous, but not magnificent. There are the usual large buildings of British civil administration. As a railway terminus, N. is the centre of a great and increasing trade. The chief imports are grain, salt, and European goods; total value, about £500,000. The grand article, both of manufacture and export, is fine cloth; total value of exports, £120,000. N. city was founded about 1700 by Bukht Bulund, one of the last of the Gond dynasty, whose descendants still survive as state pensioners. The Mahratta family of the Bhonslas conquered the country in the middle of the 18th c. They were powerful enough to overrun Bengal, and permanently occupy Orissa; but they were defeated by Wellington at Assaye and Argaum. Nevertheless they continued to give much trouble to the British until the state of N. was annexed by Lord Dalhousie, after the death of Raghoji III. without heirs in 1853.—The *district* of N., which presents great variety of surface, has an area of 3734 sq. miles; pop. (1872) 631,109. The staple crop is wheat, and of late years cotton has been extensively grown. There is a peculiar breed of trotting bullocks, that will draw a light cart 30 miles in five hours. Weaving is carried on in every village, and the finer sorts of cotton and silk cloths are in demand throughout India. The balance of trade is in favour of the district, and the banking firms of Marwaris or Jains make large profits. During the Mutiny of 1857, the Madras regiments at Kampti stood firm, but it was found necessary to disband the cavalry regiment of N. irregulars. See Grant Duff's *History of the Mahrattas* (Lond. 1826), and Grant's *Gazetteer of the Central Provinces* (Bomb. 1870).

Nag's Head Consecration. When Elizabeth revised the Prayer Book and passed the Act of Supremacy, Convocation protested against these things; and when she desired to have Matthew Parker consecrated Archbishop it was found that only five of Edward's hierarchy had survived the Marian persecutions, Llandaff having apostatized. It requires three bishops to conse-

crate an archbishop, and Kitchen and Bale being both disreputable persons, the Queen summoned Barlow of Bath, Scory of Chichester, Hodgekins of Bedford, and the venerable Miles Coverdale to impose hands at Lambeth on 17th December 1559. This was duly done according to the ordinal of Edward VI. The stupid story that on account of a prohibition from Bonner, Scory performed the consecration by laying a Bible on Parker's head in Nag's Head Tavern, Cheapside, probably arose from the fact that after the *congé d'lire* was originally issued, and several bishops summoned, they refused to officiate or tolerate the oath of supremacy, and were therefore deprived. Accordingly, the consecration was actually carried through by bishops, some ordained according to the Roman Pontifical, and others according to the reformed ordinal; and the Queen's second mandate bears a clause supplying all deficiencies there might be in the proceeding according to the statutes of the realm or the laws of the Church. (*Lingard*, v., p. 631.)

Nagy (pron. *Nadji*), a Magyar word signifying 'great,' prefixed to the names of several Hungarian towns. Of these Banya, Karoly, and Kikinda are given under those headings, and N. Varad and N. Szombat under their German names Grosswardein and Tynau.

NAGY-ENYED, a town of Transylvania, on the Maros, 18 miles N.N.E. of Karlsburg by rail, has a celebrated Calvinist academy. Pop. (1869) 5779.

NAGY-KOROS, a market-town in the comitat of Pesth, 55 miles S.E. of that city by rail, with a large gymnasium, and a trade in sheep, cattle, and wine. Pop. (1869) 20,091.

NAGY-SAROS-PATAK, a market-town in the comitat of Zemplin, on the right bank of the Bodrog, contains a Calvinist college, with a fine collection of minerals, and a library of 25,000 volumes. Pop. (1869) 5366, who make wine and manufacture cloth.

NAGY-SZENT-MIKLOS, a market-town in the comitat of Torontal, on the Aranka, 37 miles E.S.E. of Szegedin by rail, has an Agricultural Institute, and a trade in wine and grain. Pop. (1869) 9205.

Nahum (Heb. 'consolation'), the Hebrew prophet, is styled in the superscription of his book the Elkoshite, i.e., a native of Elkosh, understood to be Elkesei in Galilee, or according to some, Elkosh on the E. of the Tigris. The Book of N., which is the seventh of the 'minor' prophets, is all directed against Nineveh and its king, both being threatened with destruction for their hostility to Jehovah and his people. As to the time of the prophet, there is hardly a reign from that of Jehu to Zedekiah under which he has not been placed by some critics. The majority make him a contemporary of Hezekiah, and his prophecy to have been delivered soon after the siege of Jerusalem by Sennacherib, about B.C. 711 (Isa. xxxvii. 36).

Nāhun, or **Sirmūr**, the capital of the native state of the same name in N.W. India, at the foot of the Himalayas, 128 miles N.E. of Delhi. It is a particularly well-built and clean town; the houses are of stone, and the streets paved. The palace is handsomely carved.—The state of N. ranks first among the hill states of the Punjab; it is crossed by the Giri River, and lies between the British districts of Dehra Dūn and Umballa. Area, 1096 sq. miles; pop. 90,000; revenue, £28,500. The Rajput dynasty dates from the 11th c. They were restored by the British after the Goorkha War of 1803, and were loyal during the Mutiny.

Naiada'cese, or **Juncagina'cese**, a natural order of monocotyledonous submerged fresh, or salt-water plants, found in all climates of the globe, and numbering about twenty genera and 100 species. The flowers, with few exceptions, are inconspicuous, and the properties of the order may be classed as unimportant. In Britain there are numerous representatives, but they only have an interest to the botanist. The riband-like leaves of the grasswack (*Zostera marina*) are sometimes used for packing purposes, and by upholsterers for stuffing mattresses and cushions; a patent has also been taken out for their manufacture into paper. The Lattice-leaf (q. v.) of Madagascar is an attractive curiosity. The Cape pondweed (*Aponogeton distachyon*) is grown as a fragrant ornamental aquatic, and at the Cape the starchy tubercular rhizome is roasted for food, and the flowering tops are used as a pickle, and as asparagus.

Nai'ade, the general designation of the nymphs of the fresh water, whether of lake, river, or fountain. Certain waters or springs presided over by the N. were supposed to inspire those who drank therefrom, hence these nymphs were thought to be possessed with oracular power, and to impart to mortals the gifts of prophecy and poetry. From this circumstance seers were sometimes termed *nympholeptoi* (nymph-struck). The N. were an inferior order of female divinities, designated, nevertheless, Olympian, and described as the daughters of Zeus. As conferring life and blessings they were worshipped with Dionysus and Demeter; in their prophetic character with Apollo; while as tenants of lake and stream, they mingled on green bank and vale with Pan, the Sileni, and the Satyrs, in the gamesome revel and the dance. They are usually represented in works of art as lovely maidens, nude or nearly so. Goats, lambs, milk, and oil were offered to them, but never wine. See **NYMPHS**.

Nail (Old Eng. *naegl*, comp. Ger. *nagel*; allied to Lat. *unguis*, Gr. *onyx*, Sansk. *nakha*), the name given to the horny plate forming a skin appendage in vertebrate animals. It is a typical example of the *horny tissues* of the body, in the chemical composition of which an albuminous substance in combination with sulphur is found. There is a larger proportion of the latter element in horny tissues than in albumen or fibrine. A N. consists essentially of an arrangement of the cells of the Epidermis (q. v.) or outer layer of the skin. In vertical section it is composed below of rounded or elongated cells; those of the upper part of the N. being flattened and more markedly horny than the under. The N. is formed, like the epidermis itself, as a secretion of the *dermis* or true skin, the N.-producing surface being termed its *matrix*. The *root* of the N. is the part lying next the matrix, and is embedded in a semicircular groove in the latter. The *bed* of the N. is the somewhat flattened part of the skin on which it rests, and is composed of a number of parallel ridges, forming the cells of the N. The N. thus grows in length from behind—new matter being formed by the *matrix*—and in thickness from below through the new material contributed by its bed. Hoofs, claws, and like organs are merely modifications or excessive developments of nails. *Ingrowing* nails are a troublesome affection requiring skilful surgical treatment.

Nail, an implement of almost universal use, but varying so much in size, material, and application, as almost to defy general definition. A common N. is, however, a tapering spike of iron, headed at the thick end, employed in joining and fastening together all kinds of joinery and woodwork. The N. has been known and used from the most remote antiquity, and indeed, considering its simplicity of form and indispensable utility, it may almost certainly be said to be coeval with the use of metal in any form. Nails are of three leading kinds—handmade or forged nails, cast nails, and machine-made or cut nails. In the hand-made N.-trade, again, three subdivisions are recognised, these being 'thousand' work, 'hundred' work, and fariery, or horse-shoe nails. 'Thousand' work consists of nails of a small size, while 'hundred' work includes heavy nails, spikes, &c. The work is conducted at the homes of the operatives, attached to which are small smithy hearths termed 'N.-shops,' and the material—'N.-rods'—is supplied by the N.-masters, or middlemen, called factors or 'foggers.' Women and small children perform much work of a character unsuited for them, and the social condition of the nailers or N. villages is of the most wretched description. The great centre of the N. trade of Great Britain is in the Midland hardware district, and in Dudley, Walsall, Bromsgrove, and Halesowen it forms with chainmaking the leading industry, while it is also prosecuted extensively in Birmingham, Wolverhampton, and other towns. Hand-made and farriers' nails are also extensively made in the village of St. Ninians, near Stirling, but there the men are industrious, sober, and prosperous. Cast nails are of limited application, and are principally used for studding the soles of boots and shoes. For the manufacture of 'cut' or machine-made nails a great variety of ingenious and complex machinery has been adopted, and by far the greater proportion of the nails now in common use is made by machinery. For some machines the iron is heated to a forging heat, while in others the operations of cutting and heading are performed on metal rods or plates in a cold condition. The machinery invented in 1873 by Mr. Whittle of Harborne, near Birmingham, is the best yet devised for the manufacture of hot wrought nails. The quantity of nails turned out in a given time is double that at

tained by any previous machinery, while the tear and wear of the cutting instruments have been greatly reduced. Nails and brads are also punched out of plate iron, the punches being so

arranged that headed nails are cut out without any loss of metal, as shown in the accompanying diagram, in which *A* shows brads with heads on one side, and *B* represents nails with a head projecting over both sides.

Nain de Tillemont. See TILLEMONT.

Nain Singh Pundit, a native of India, on whom the Royal Geographical Society conferred its gold medal in 1877, on the ground that he had 'added a greater amount to our positive knowledge of the map of Asia than any individual of our time.' He is a native of Kumaon, and commenced his career as an explorer in 1856 with the brothers Schlagentweit, the Himalayan travellers. Subsequently, as a subordinate in the Trigonometrical Survey, he traversed the whole plateau of Thibet, and fixed by observations the upper course of the Brahmaputra and the site of Hlassa. He has now retired on a pension of £50 a-year.

Nairn, a royal burgh, and chief town of its county, is situated on the W. bank of the river N., where it enters the Moray Firth, 15 miles N.E. of Inverness by rail. It commands splendid views of the opposite coast of Ross-shire, distant 8 miles, and attracts a great number of visitors in summer by its excellent sea-bathing and artificial baths. The town, which has a good harbour, a museum, newspaper, &c., unites with Inverness, Forres, and Portrose in sending a member to Parliament. Pop. (1871) 3751. In the vicinity is Cawdor Castle, where, according to tradition, King Duncan was murdered by Macbeth.

Nairne, Caroline Oliphant, Baroness, a Scottish poetess of rare genius, was the third daughter of Laurence Oliphant of Gask, and was born at the mansion-house of Gask, in Perthshire, 16th July 1766. Her beauty was such that she was called the 'Flower of Strathearn.' In June 1806 she married William Murray Nairne, then an officer in the British army, who in 1824 succeeded to the title of Baron Nairne, which had been attained since the Rebellion of the Forty-five. The Baroness survived her husband fifteen years, dying at Gask, 27th October 1845. During the last years of her life she evinced a deep interest in religion, and was particularly attached to the Free Church movement, though her charities, which were numerous and varied, took no sectarian shape. Except to a very few friends, she never divulged the secret of her authorship; and while all Scotland was ringing with the *Laird o' Cockpen*, *The Land o' the Leal*, *Bonnie Charlie's now awa'*, *The Auld House*, *There grows a Bonnie Brier Bush*, *The Hundred Pipers*, &c., she remained absolutely unknown to her countrymen. There is an exquisite womanliness in her lyrics. Everything, whether humorous or serious, is tenderly, delicately, gracefully touched; and everywhere there is stainless purity in word and sentiment. In 1850 Paterson & Sons, Edinburgh, published the first edition of the Baroness N.'s *Lays from Strathearn*, with pianoforte accompaniments by Finlay Dun. The seventh edition of this most beautiful collection appeared in 1876. See Charles Rogers' *Memoirs and Complete Lyrical Compositions of the Baroness N.* (lond. 1869).

Nairnshire, a county in the N. of Scotland, bounded N. by the Moray Firth, S. and E. by Elgin, and W. by Inverness. Area, 137,500 statute acres; pop. (1871) 10,225. It is rugged and mountainous in the S. and E., and is drained by the rivers Nairn and Findhorn. The formation in the N. is mainly old red sandstone, in the S. gneiss, and in the W. granite. Agriculture is in an advanced state, and part of the soil is light and sandy. In 1870 there were 9614 acres under corn crops, 4856 under green crops, 9973 in clover, sainfoin, and grasses, and 1536 in permanent pasture, exclusive of mountain and heath. N. had

in the same year 1220 horses, 6443 cattle, 15,089 sheep, and 820 pigs. The chief crops are barley, oats, wheat, turnips, and potatoes. The climate is singularly mild and steady; the rainfall does not exceed 26 inches. Besides the chief town of Nairn, the county includes the villages of Cawdor and Auldearn, the former celebrated for its great monthly cattle 'tryst.' N., together with Elginshire, sends one member to Parliament.

Nairs, the dominant Hindu tribe on the Malabar or W. coast of S. India, to whom the Zamorin of Calicut belonged. They are a warrior caste, claiming to be second only to the Brahmans. In old times they never went abroad without a knife or crooked sword, which they were ready to draw on all inferiors. They do not recognise the marriage tie; and consequently all descent and inheritance to property is traced through the female line—a custom which still governs the succession to the throne in the native states of Travancore and Cochin on the Malabar coast.

Nais and **Naididæ**, a genus and family of *Annelida* (q. v.), or worms related to the Earthworm (q. v.). They are found in freshwater streams. A familiar example is the *Tubifex rivulorum*, a worm that occurs in the mud of ponds, and is about half an inch in length. It has a bright pink body. The N. have the power of increasing by *gemmation* or *budding*. A bud thrown out near the middle of the body becomes a new individual, and the parent body may also separate into two or more distinct creatures.

Naissant, in Heraldry, an epithet applied to an animal rising from the middle of an ordinary, thus contrasted with *Issuant*, which is applied to whatever comes from the bottom of a chief.

Naja, a genus of *Colubrine* snakes, belonging to the *Venomous* section of the latter group, and represented by the Cobra da Capello (*N. tripudians*) of India, and by the Egyptian Cobra (*N. haje*). They are among the most deadly of their kind, and have *canaliculated* poison-fangs in the upper jaw, with small solid teeth behind. See COBRA.

Naked-Eyed Medusæ. See MEDUSIDÆ.

Nakhichevân, a town in Russia, government of Ekaterinoslav, on the river Don, 28 miles from its mouth, and 45 miles E. of Taganrog by rail. N. was founded in 1780, is the seat of an Armenian archbishop, and manufactures silks, cottons, Morocco leather, and brandy. Pop. (1870) 16,258.

Nakoo, a name applied to the Gavial (q. v.).

Nalagarh ('brook-fort'), the capital of a native state of the same name in N.W. India, among the lower slopes of the Himalayas, 1094 miles N.W. of Calcutta. It is a place of considerable strength, and was bombarded and taken by General Ochterlony during the Gurkha war of 1803.—The *state* of N., which is also known as Hindur, forms one of the hill states of the Punjab; it lies N. of the British district of Unballah. Area, 400 sq. miles; pop. 70,000; revenue, £9000; tribute, £500.

Namagualand, the name of an extensive region in S.W. Africa, divided into Great and Little N.—(1.) **Great N.** extends from Walvisch Bay in 23° S. lat. to the Orange River in 28°30' S. lat., and from the Atlantic eastwards to the Kalahari Desert (q. v.), an area computed at 100,000 sq. miles. The northern portion of this region consists of a plateau varying in height from 3000 to 5000 feet above the sea-level, and tolerably fertile. By far the most of the country, however, is a sterile, rainless tract, nearly devoid of vegetation. The geological formation is chiefly gneiss and granite, the latter when it rises into hills being rounded or flattened, and not in sharp peaks. Streams are few and insignificant, what drainage there is being carried off by watercourses whose beds are often dry. Of these the chief is the Great Fish River, which after a course from N. to S. of 450 miles unites with the Orange River, about 90 miles from the mouth of the latter. The coast is a dreary waste of sandy plains, but vessels may anchor in safety in Walvisch Bay, Sandwich Bay, and Angra Pequena. Ichaboe Island, and others on the coast contain guano, and a whale-fishery is also carried on. The country is rich in copper ore, and deposits of argentiferous lead are also known to exist, but neither are yet worked, on account of the cost of transport. Lions, rhinoceroses, giraffes,

and the larger antelopes are still numerous, though decreasing in numbers since the natives obtained firearms, and the hippopotamus is found in the N. The pop. of Great N. probably does not exceed 50,000.—(2.) **Little N.** is an electoral division of Cape Colony, of which it forms the N.W. portion, and is divided from Great N. by the Orange River. Up to 1865 it formed part of the division of Clanwilliam. Little N. has an area of 21,000 sq. miles, with a pop. estimated in 1876 at only 10,000. The seat of government is at Springbok Fontein. The coast region is buried in sand, and is succeeded by rugged mountains which attain a height of 5300 feet, and expand to the eastward into grassy plateaux. Scarcely any rain falls, and settlement is consequently confined to the neighbourhood of the Orange River, and one or two other streams. The climate is liable to great extremes, the range of the thermometer frequently being as much as 60° in twenty-four hours. The country is chiefly of value for its deposits of copper, which, although they were worked for a time by the Dutch 200 years ago, have only been remuneratively worked since 1853. The principal mine is at Ookiep, 60 miles from Port Nolloth in Robbe Bay, the place of shipment, with which it is connected by rail. The Ookiep ore is of the first quality, and the quantity seems to be unlimited. The larger kinds of game have been exterminated in Little N., with the exception of ostriches.

Namaquas, the name given by Europeans to the Hottentot tribes inhabiting Great Namaqualand, though they call themselves Topnaars and Oerlams. They possess the physical peculiarities of the Hottentots (q. v.), but are a much finer race than the Bosjesmans (q. v.). They own cattle, goats, and sheep, and lead a half pastoral, half predatory life, yielding allegiance of a modified kind to a number of petty chiefs. The northern tribes, under their chief, Afrikaner, long carried on a war of extermination against their neighbours the Damaras. Morally, the N. are a low race, Andersson declaring that 'they possess every vice of savages and none of their noble qualities.' Idleness and ingratitude seem to be their principal characteristics; while, until the missionaries came among them, they had scarcely any idea of the existence of a Divine Being, and they are still largely under the sway of sorcerers. Polygamy is universal among them, and tattooing is also common. The N. probably do not number more than 50,000, and they are gradually disappearing before the advance of the Griquas.

Name (Old Eng. *nama*; comp. Ger. *name*, Lat. *nomen*, Gr. *onoma*, Sansk. *nāman*, from a root meaning 'to know'; hence 'that by which you are known'). The primitive rule in naming seems to have been 'one name one person.' Surnames and the multiplication of names came later. The baptismal was given at birth, or at a certain period after, at puberty; the power of selecting being in the father, subject to customs, such as that in Greece which pointed to the N. of the paternal grandfather. In some savage nations, e.g., the Samoans, the N. is given long before birth, no difference being observed in naming the sexes. Marriage produced important effects: at Rome, the woman taking the feminine of her husband's prænomen; in Spain both surnames are retained, so that children have a choice; elsewhere the maiden surname is dropped from colloquial use, though not from legal designation, but the maiden Christian name remains unaltered. The Jews were the fruitful creators of single proper names, nearly all of them expressing the strong domestic or religious affections of the people. Greek names bear more frequent reference to personal appearance or the features of the human character, and were often supplemented by the occupation, place of birth, or a nickname. In the Roman prænomen, gentilicium, cognomen, and agnomen (Publius Cornelius Scipio Africanus) we have the individual (there was a very slender stock of *prænomina*), the gens, the familia, and the public distinction; but colloquially, only the first and third were used. With regard to the names of modern Europe, it may be observed that tradition gives us very little aid in tracing their origin. The stories about Turnbul and Lockhart are unfounded. The Latinisation of names, too, is very misleading; as when Armine is attempted to be made into Sancta Ermina, or Dimoak into De umbra quercu. In fact, the study of English names embraces a wider field than that of the English language, because while the spoken dialects of Old English were fused into one, the names were not. Some of the shorter names are of extraordinary antiquity; e.g. Seymour (Sigirner, father of Arminius, a name also surviving in Siggs);

Nibbs, probably connected with Neibelung and Neville. These names are partly derived from original surnames (which did not come into settled hereditary use much, if at all, before the Conquest).^{*} All of them, though not changing with the general body of the language, have been subject to phonetic mutations, but so partially that we find existing together the different stages of their development; as Hagle and Hail (Old Eng. *hagl* or *hægl*), Wegg and Way (Old Eng. *weg*), Gum and Groom (Old Eng. *guma*). Names which approximate to an apparent meaning are readily corrupted into a familiar sound; as Ashketele, Goodluck, Thoroughgood, for Asketil, Guthlac, and Thurgood. This is sometimes done consciously from superstitious motives; as when Maria Theresa, whose minister Tunicotto's name had been corrupted into Thunichtgut, altered it to Thugut. Even in such cases as Bastard, Harlott, Wanton, Outlaw, Scullion, Coward, Vas-al (all names in actual use), it is almost certain that the apparent meaning is only a coincidence. Again such names as Purchase, Pardon, Vinegar, Power, Pilgrim, Marigold, Dandelyon, are distinctly compounds. The simplest and most ancient forms consist of one syllable with a terminal vowel, *a*, *i*, or *o*: Ella, Coll, Hanna, Bynni, Betti, Cuddi, Dodo, Odo, most of which may be seen in the Domesday Book or Liber Vitæ of Durham. These root names are variously modified by the seven diminutives (*k*, *l*, *kin*, *lin*, *s*, *us*, and *m*), as in Garrick, Wilkin, &c., by phonetic additions, such as *u* or *r* at the end of a simple N. or some liquid in the middle of a compound N. *Ing* and *son* are the great German and Scandinavian patronymics; the final *s* being more frequently a phonetic. Most compound names have no meaning at all—e.g., Arnulf (eagle wolf), Zeizolf (darling wolf)—they are merely two proper names put together. Of course, many of the terminations of compound names have been common substantives, as *am* or *iam* from *helm*, helmet; *bert* from *beorht*, bright; *red*, *rat*, or *ret* from *red*, counsel, &c. The usual changes between High and Low German take place, as *t* for *d*, *s* or *z* for *t*, *sch* for *s*, *b* for *v*, *p* for *b*, and *k* for *g*. The Frankish dialect often turns the aspirated *l* or *r* into a distinct *e*, while the German often prefixes or affixes a *g*. But it is impossible to do more than suggest the causes which have brought names into their present condition. A very large number of French names, both Christian and surnames, are German. A large class of names, suggested by mann, carl, guin, alba, &c., simply refer to man as the type of power. The family names, apparently formed from women's names, are often just ancient men's names, and do not indicate illegitimacy. The sacred animals, wolf, bear, boar, and horse, contribute a good many names; but, as in the case of trades, so in many cases of apparent derivation from animals the names come from a totally different source. Among birds, the eagle, the raven, and the crow give most names. The word god, with its Scandinavian relatives *us* or *os* and *ans*, and the forty-nine titles of Odin are responsible for a large number. So with the other gods and heroes; the names which, like Hild, Gund, Hub, Coll, Bald, &c., suggest the warrior and his arms. Another series, of which Frid, Wine, Liub, Bil, Dod or tot, Bul, Geben, are examples, expressed originally ideas of protection and friendship. Others again clearly refer to all the relations of kinship. Many names represent nationalities, or the more general idea of 'guest' or 'sojourner,' and have therefore been given to strangers by those among whom they lived. The associations of sea and sea-life; the relations of ruler and prince; the ideas of wisdom, knowledge, fame, wealth; all the personal features of a man, both bodily and mentally; his station in life and trade; herbs, metals, &c., always with some figurative reference, also furnish names. Of course the Christian Church introduced a great many Scripture names; but many apparently scriptural names (the familiar diminutives of some which are really so) have a different origin. Names of places are often taken from persons and then given back to persons: as Dodd's worth, Grim's By; and this process may be repeated twice over, as in Montgomery. The principal local surnames are Bank, Bech, Bower, Cross, Dale, Frith, Gill, Hedge, Hill, Ing, Moss, Orchard, Pitt, Pool, Ridge, Slade, Street, Wall. On the other hand, House, Inn, Home, Wood, &c., are probably from ancient baptismal names. Some names of parishes, as Burnard,

^{*} The earliest known English surname is *Hatto*, though prefixes like *as* and *hilde* may have been used by noble families before, and partly from ancient single or baptismal names.

Guthrie, Jellybrands, Lockhart, Osborn, Sibbald, and Thorbrand, all in Scotland, seem to be the names of men. The local terminations, ton, ham, burg, by, den, force, garth, gate, gill, holt, hope, howe, hurst, over, shaw, sted, stow, ster, thorp, thwaite, toft, wick, vidr, are all pretty well known. Finally, this subject is not without its comicalities. In the London Directory there are five dealers in potatoes named Mash; in Paris there are wine merchants named Porte, Claret, and Champagne, a physician named Verjus, a hair-dresser named Saladin, a tailor named Clovis, and a grocer named Milord. Mineuve is a lemonade-seller, Thais the lady-superior of a religious order, and Madame Mizery keeps a hotel. See Förstmann's *Alt-deutsches Namenbuch* (1856); Pott's *Die Personennamen* (1853); Kemble's *Names, &c., of the Anglo-Saxons* (1846); Lower's *English Surnames* (1849), and *Patronymica Britannica* (1860); Yonge's *History of Christian Names* (1863); Taylor's *Names and Places* (1864); Ferguson's *Teutonic Name-System* (1864); Innes' *Scotch Surnames* (1860); Joyce's *Irish Names of Places* (2 vols. 1869-75); and Bardsley's *English Surnames* (2d ed. Lond. 1875).

Namur' (Flem. *Namen*), a province of Belgium, bounded N. by Brabant, N.E. by Liège, E. and S.E. by Luxemburg, S. by France, and W. by Hainault. Area, 1417 sq. miles; pop. (1874) 316,331, chiefly Walloons. N. is watered by the Maas (q. v.) with its affluents the Lesse and Sambre, and is finely diversified with well-wooded offsets of the Ardennes. In the S.W. part ('La Fagne') are wide moors; in the N. and E. ('Condroz') rich pastures and cornlands. N. abounds in coal, iron, lead, zinc, manganese, sulphur, alum, lime, and marble. It is traversed by two main and several branch lines of railway. Already in the 10th c. N. was an independent county, and was successively united to Hainault, Luxemburg, and Flanders (1261). In 1420 it was sold by Johann III. of N. to Philipp of Burgundy for 132,000 gold crowns. After this it was one of the seventeen Netherland provinces. At the Peace of Lunéville (q. v.) N. fell to France, but from 1814 it formed a province of the Netherlands, and in 1831 was transferred to the new kingdom of Belgium.—**N.**, a fortified town in Belgium, capital of the province of N., lying between two hills at the confluence of the Maas and Sambre, and at the junction of five lines of railway, 36½ miles W.S.W. of Liège by rail. It is a bishop's see, and has seventeen churches, of which the finest are the cathedral, or church of St. Aubin (1772), and the Jesuit church of St. Lupus, dating from the beginning of the 17th c. The chief industries of N. are the manufacture of cutlery, hardware, leather, and chemicals, and the working of coal and marble. Pop. (1873) 23,380.

Nan'a Sah'ib (*Nana* = a maternal grandfather), the name by which the infamous instigator of the Massacre of Cawnpore is known in history. His real name was Dundhu Punt, and he was born about 1820, of Brahmin descent, and a near relation of the Peishwa (q. v.), the dispossessed hereditary prime minister of the great Mahratta confederacy, by whom he was adopted. On the death of his adoptive father in 1853, the British Government, in accordance with the strict letter of the original treaty, refused to continue in his favour the pension of £80,000 per annum which the ex-Peishwa had received. N. S., despite many memorials and a mission to London, was only allowed to hold rent-free the site of the palace of Bithur, 10 miles W. of Cawnpore. There is no doubt that he forthwith commenced intrigues against the British power in India; but he was so little suspected, that on the outbreak of the Sepoy Mutiny at Cawnpore in May 1857, his treacherous offer of assistance was accepted by the British general. He immediately placed himself at the head of the mutineers, and was proclaimed Peishwa with great magnificence. After a month's siege, the Europeans at Cawnpore capitulated to N. S. on a promise that they should be sent down the Ganges in safety; but before they had all got on board the boats, the premeditated massacre began. The men were shot down, and the women and children taken back to Cawnpore, to be miserably cut to pieces in the following month, by the direct orders of the Nana, after his defeat by Havelock. Four Englishmen alone fought their way to safety, of whom Colonel Mowbray Thomson is now the sole survivor. The Nana fled into Rohilkund; and after a series of engagements he is known to have been driven across the frontier into Nepaul, but there all direct knowledge of him ceases. Some say he perished of fever in the jungle; but the general opinion is that he escaped into Central Asia. More than once in recent years

his capture has been announced. As late as 1875 Scindiah, Rajah of Gwalior, arrested with his own hand a person whom he asserted to be N. S., but who turned out to be a mere fanatic, though a strong suspicion exists that the real personage did then pay a visit to Gwalior. See Sir J. Kaye's *History of the Sepoy War*, Col. M. Thomson's *Personal Reminiscences*, and *Cawnpore* by G. O. Trevelyan.

Nancy (from the Celt. *Nant*, 'a brook,' or 'valley through which flows a brook'), the chief town of the department of Meurthe-et-Moselle, France, on the left bank of the Meurthe, 35 miles S. of Metz by rail. Surrounded by a rich wine-growing country, it is one of the finest cities in France, entered by several imposing gates, and having many spacious streets lined with magnificent houses, and various public squares adorned with gardens and fountains. It has celebrated schools of medicine, pharmacy, and forestry, besides a lyceum, a library of 26,000 vols., valuable art and scientific collections, and manufactures of embroidery (400 factories), cottons, woollens, linens, candles, &c. Pop. (1872) 52,978. N. was the residence of the Duc de Lorraine from the 13th c., and in the vicinity a battle was fought between Charles the Rash and René II., in which the former was defeated and slain, 5th January 1477. Stanislas Leszczyński, the ex-king of Poland, did much to beautify the town, and on his death in 1766 Lorraine fell to France. N. was captured by Blücher in 1814, and after the retreat of MacMahon's army surrendered to the Germans, 12th August 1870, but was restored at the peace.

Nandu' (*Rhea Americana*), a species of *Rhea* or American ostrich, a Cursorial bird inhabiting S. America, especially La Plata. It attains a height of five feet, and is of a dark grey colour, the upper parts being blackish. The wing-quills are white, and the neck is encircled by a black band, and feathered. As in other Cursorial birds, the feathers are destitute of webs. Their hairs are loose and disconnected. The N. is gregarious, the flocks numbering from fifteen to thirty. The food consists of grasses and roots. The eggs may number twenty-two. The N. is readily tamed. This name is also given to other species of *Rhea*, as the *R. Darwinii* and the *R. macrorhynchus*.

Nankeen', a buff coloured or brownish yellow calico manufactured in China from a variety of cotton naturally possessed of that particular colour. In European countries the colour is artificially produced by dyeing white calico with a tannin solution after mordanting with alum and clearing with nitro-muriate of tin.

Nanking' (i.e., 'Southern Court'), the former capital of China, and the chief town of Kiang-Su, is situated in a marshy, unhealthy plain, on a branch of the Yang-tse-Kiang, 3 miles above the point of confluence, and 200 miles from the mouth of the greater stream. The remains of its ancient wall have a circumference of 35 miles, and according to Chinese accounts the population at one time amounted to 4 millions; the modern wall is 40 feet high, and 18 miles in circuit, but great part of the area is now a dreary ruin-encumbered waste. N. was the court of the Ming dynasty from 1369, till Yang-lo removed it to Peking in 1410, after which the city began to decline. Still it not only retained the outward show of grandeur in its splendid architecture, but continued to be a famous seat of learning, with great libraries and other institutions, as well as the centre of a wealthy commerce. It was taken (19th March 1853) by the Tai-pings, who held it as a stronghold of rebellion for eleven years. When recovered by the Imperialists (19th July 1864) its glorious monuments had been wrecked, and its sources of wealth scattered to the winds. The rebels had totally destroyed the world-famed Porcelain Tower, an octagonal structure 322 feet high, built of coloured bricks, lighted by 140 lanterns, and supporting 144 bells, erected by the emperor Yung-lo, 1413-32. Most of the ancient palaces have wholly disappeared, but outside the city are the splendid remains of the imperial Summer Palace. Another object of interest is a singular avenue of colossal statues of camels, elephants, &c., leading to the imperial tombs. The government has made several attempts to revive the prosperity of N., but with little success. It is, however, the residence of the viceroy, the chief seat of literature in the empire, and the headquarters of a large military force; and although its commerce is comparatively slight, it has an arsenal on a European model, and some manufactures of the once famous *nankeen*

cloths, satins, silks, crape, and paper. Pop. 300,000. The treaty between England and China, by which European merchants and a British consul were allowed to reside at the five 'treaty ports' was signed here, 29th August 1842. The British, under Major Gordon, helped to crush the Tai-pings in 1864.

Nantes (named from the *Nannetes*, Celt. 'the dwellers in the river-valley'), a city of N.W. France, capital of the department of Loire-Inférieure, lies on the right bank of the Loire, at the confluence of the Erdre and Sèvre with that river, 33 miles from the sea, and 58 miles S.S.E. of Rennes by rail. It is noted for the beauty of its streets and public buildings. Of the five suburbs of N., three will bear comparison with the finest parts of Paris. Numerous bridges connect the banks of the river with the islands in its channel. The most noteworthy buildings are the cathedral of St. Pierre, dating from the 14th c.; the castle of the Dukes of Bretagne, built in 930, whence Henri IV. issued the Edict of N.; and the churches of St. Nicholas, Ste. Croix, St. Louis, St. Clement, St. Donatien, and Ste. Anne; the Bourse (1809); the theatre (1787); the hospital of St. Jacques; the Hôtel-Dieu; and the Salorges or great warehouses for colonial goods. N. has numerous schools and museums of art and science, a library of 90,000 vols., and the best provincial picture gallery in France. At N. the tide rises only five feet, hence the largest vessels unload at St. Nazaire (33 miles off), and their cargoes are conveyed to N. by rail or in barges. Through recent improvements of the riverbed, ships that could formerly only reach Paimbœuf can now enter the harbour of N., which has room for 200 vessels. In 1876, there entered and cleared 66 British ships of 9747 tons. The chief industries are sugar-refining, shipbuilding, and the manufacture of cannon, ship's boilers, linens, cottons, sailcloth, flannel, chemicals, leather, and brandy. The yearly exports of N. are worth 2½ million (corn above one million), and exports 2½ millions sterling. In 1876 there were imported 54,476 tons of raw sugar, and exported 8106 tons of refined sugar. On an island 6 miles W. is the large government steam-engine factory of *Indret*, and in the S.E., near the Sèvre, is *Palut*, the home of Abelard. Pop. of N. (1872), 118,517.

Nantes, The Edict of, was signed by Henri IV. at that city, April 13, 1598, and received the assent of the French Parliament, February 25, 1599. In ninety-one public, and fifty-one secret articles, it allowed to the French Protestant Church (q. v.) the free exercise of its religion, except in certain towns, as Rheims and Soissons; it threw open to Protestants all offices of State; and it assigned a yearly sum of upwards of £6000 to the support of their pastors. The Edict was confirmed by Louis XIII. in 1614, and again in 1622, and though often infringed by Richelieu and Mazarin, remained in force until, in 1684, Louis XIV., at the instigation of Madame de Maintenon and Père La Chaise, commenced that system of persecution known as the Dragonnades (q. v.), which finally resulted in the formal revocation of the Edict, October 23, 1685. See *Ruthière, Éclaircissements Historiques sur les Causes de la Révocation de l'Edit de Nantes* (2 vols. Par. 1788), and Smiles, *The Huguenots* (Lond. 1874).

Nantucket, an island off the coast of Massachusetts, 28 miles S. of Cape Cod peninsula, is 15 miles long by 4 wide, and with four smaller islands has an area of 60 sq. miles. Its soil is light, and almost treeless. The town of N., in the S. of the island, has nine churches, two banks, and one weekly newspaper. Pop. (1870) 4123.

Nant'wich (Cym. *nant*, 'valley,' and Scand. *wic*, 'salt-works'), a market-town of England, in Cheshire, on the Weaver, 20½ miles S.E. of Chester by rail. The chief buildings are the cruciform church of Sts. Mary and Nicholas (restored 1866), the town-hall (1858), mechanics' institute, grammar-school, &c. The once famous saltworks of N. have been totally abandoned, and shoemaking and the manufacture of gloves, leather, and cotton are now its leading industries. Pop. (1871) 7234.

Nanuk, the founder of the Sikh religion, was born near Lahore in 1469, of the Rotri or trading caste. He travelled widely as a religious devotee, and studied the religious books both of Hindus and Mohammedans. 'Several Korans and Puranas had he read, but one God had he not found.' Finally he abandoned the garb of an ascetic, returned to his family, and

passed the remainder of a long life in teaching men to worship the One Almighty Invisible God, to live virtuously, and to be tolerant of the failings of others. He admitted the authority of Mohammed and also of the Hindu incarnations, and inculcated alike veneration for the cow and abhorrence of the hog. He died in 1539, but his spirit is believed by the Sikhs to have been transmitted to each successive *gooroo* (q. v.). Many of his sayings are embodied in the *Grunth* (q. v.) or Holy Book of the Sikhs. Outside the Punjab his followers are often called Nanuk-shahis. See Cunningham's *History of the Sikhs* (Lond. 1853).

Naph'tali was one of the twelve tribes of Israel, numbering at the first census 53,400 fighting men, and at the second 45,400 (Num. i. and xxvi.), which had its territory in the extreme north of Canaan. It is held by some Biblical scholars that the writer of Genesis xxix. and xxx., who gives a detailed account of the birth of Jacob's sons, with an explanation of all their names (N., 'my conflict,' that is, in prayer with God for his mercy, which had seemed to be restricted to Leah), had the definite purpose before him of assigning to each of the tribes its proper rank and importance. According to this theory N., the son of Rachel's slave Bilhah, was inferior to the sons of Rachel and Leah, although superior to the two sons of Leah's slave, as Rachel was nearer Jacob's heart than Leah.

Naph'tha (Arab. *nafth*, from *nasatha*, 'to boil') was originally a term applied only to the liquid inflammable hydrocarbons which are obtained from the earth in many parts of the world, and which now are more generally recognised under the name petroleum. At a later period the term covered also the light and volatile oils obtained by the destructive distillation of organic substances, such as wood, bones, caoutchouc, coal, peat, &c. At the present day, although the term N. is frequently applied to all these different products, both technologically and in commerce, the native products are generally termed petroleum, the light oil obtained in the distillation of coal and shale for paraffin manufacture is known as 'spirit' or illuminating paraffin oil. Wood N. is properly known as pyroxylic spirit or methylic alcohol, and it is only to the most volatile product of the distillation of coal tar that the name N. is strictly applied. These various forms of N. all differ in their chemical constitution, and agree only in being highly inflammable and very volatile hydrocarbons, and in possessing other physical properties in common. Rock oil or mineral N. will be described under **PETROLEUM**, and for wood N. see **PYROXYLIC SPIRIT**, and **WOOD, DISTILLATION OF**. Coal Tar N., which is here dealt with, is a mixture of light oil or ethereal hydrocarbon obtained as the first product in the distillation of gas tar. The tar yields from 5 to 10 per cent. of this light oil, its richness in N. varying with the class of coal used in the previous gas making. Its constitution and properties depend upon the extent to which the heat is forced and the distillation continued, that which distils over first being richest in benzole, which is the most volatile constituent of N., its boiling point being 177° Fahr. Between the temperatures of 190° and 350° the N. distilled over consists principally of a mixture of benzole and toluole, but contains also other hydrocarbons, constituting what is chemically known as the aromatic series, as enumerated in the following table:—

Base.	Formula.	Boiling Point.	Specific Gravity.
Benzole . .	C ₆ H ₆	177°	0·850 at 60°
Toluole . .	C ₇ H ₈	230°	0·870
Xylole . .	C ₈ H ₁₀	259°	
Cumole . .	C ₉ H ₁₂	304°	
Cymole . .	C ₁₀ H ₁₄	347°	0·861 at 57°

At higher temperatures what are termed 'middle' or kreasote oils are obtained, and a third series of products obtained from the distillation of coal tar consist of the 'dead' or anthracene oils. From the light or N. oils are obtained the aniline colours of commerce, the middle oil series yields carbolic acid and the phenol colours; and from the third or dead oil is obtained anthracene, the commercial basis of artificial alizarine. For the manufacture of coal N., large iron stills capable of holding from 800 to 1500 gallons of coal tar are employed; and the distillation is effected by the direct application of steam. The rough or crude N. obtained in this first distillation is a very impure substance, containing a certain proportion of 'middle oil,' and

possessed of a powerfully disagreeable smell, owing to the presence of certain organic bases. From these organic contaminations it is freed by treatment with strong sulphuric acid in iron tanks, which, on intimate mixture with the crude N. attacks the impurities, and forms with them a tarry sludge, which, falling to the bottom, can be removed. The partially purified N. is again treated with sulphuric acid, and finally to remove all traces of the acid which may remain caustic soda is added to the N. After removal of the caustic liquor, the N. is rectified by redistillation, and it then forms the ordinary coal N. of commerce. The middle oil is separated from the light or N. oil by fractional distillation; and by the same method the commercial N. can be made to yield up the benzole and other hydrocarbons higher in the series, as enumerated in the above table. It is thus by fractional distillation that the commercial benzole, which forms the basis of the aniline manufacture, is obtained. N., and more especially benzole and the other volatile constituents of the substance, are powerful solvents, and as such are used extensively under various fanciful names for removing grease, oil, and paint spots from all kinds of textile fabrics, and for other similar purposes; but its principal use, as indicated above, is found in the aniline manufacture.

Naphthalene ($C_{10}H_8$), a hydrocarbon obtained in large quantities as a bye-product in the preparation of coal gas. By boiling with alcohol the last portions of the heavy oil which pass over at the close of the distillation of coal tar, and then allowing to cool, N. crystallises out in brilliant pearly flakes, which may be further purified by sublimation. It melts at $80^\circ C.$, and boils at 212° . It is insoluble in cold water, slightly soluble in boiling water, and easily dissolved by alcohol and ether. In itself N. is not very interesting; but its reactions with bromine and chlorine have thrown much light upon theory, and indeed suggested the now accepted doctrine of chemical substitutions, which is, that an element may be replaced in a given compound by an equivalent quantity of another element of a different chemical character. In the particular case of N., each hydrogen atom may be replaced successively by an atom of chlorine or bromine; and series of compounds may thus be obtained which show a progression in their properties as well as in their composition.

Napier, a town in the N. Island of New Zealand, situated in $39^\circ 22' S.$ lat., $177^\circ E.$ long. It was the capital of the former province of Hawke's Bay, and is the outlet of a thriving district, wool being the staple export. It possesses a small harbour, known as the Iron Pot, which vessels of 200 tons can enter, larger vessels anchoring in the roadstead. Pop. (1877) 5000.

Napier, a distinguished Scotch family, which can be traced back to the 13th c. The most notable members of it are (1) **John N.**, or **Naper of Merchiston**, who was born at Merchiston Castle, near Edinburgh, in 1550. Except that he studied at St. Andrews University, and travelled for several years upon the Continent, we know nothing of his doings till 1594. A letter of this date to Tycho Brahe from Dr. Craig, a Scotchman, mentions that N. was constructing a table of Logarithms (q. v.). How long previous to 1594 his mind had been occupied with this discovery, upon which N.'s fame as a mathematician mainly rests, we have no means of telling. The principle of logarithms was no novelty in the mathematical world at the time N. lived; but the knowledge was practically useless until methods were supplied for calculating logarithms of all numbers. This was the service which N. rendered. His tables were published under the title *Mirifici Logarithmorum Canonis Descriptio* (1614), and being intended to facilitate trigonometrical calculations contained only the logarithms of the natural sines to each minute of the quadrant, and to a radius = 10^7 . The principle of their construction was withheld, but was published in a posthumous work edited by his third son Robert, and entitled *Mirifici Logarithmorum Canonis Constructio* (1619). In spherical trigonometry he facilitated calculation by his famous *Rules or Analogies*. His *Rabdo-logia seu Numerationes per Virgulas* (1617), describing his *Bones*, was his last literary production. As a theological writer he distinguished himself by a curious fanciful work upon the Apocalypse, in which he denounced the Pope as Antichrist, and assigned the destruction of the world to the year 1786. He died at Merchiston, April 3, 1617, old style. See Mark N.'s *Life of N. of Merchiston* (1834).—(2) **Sir Charles James N., G.O.B.**, the conqueror of Scinde, and the favourite of the

British army, was a descendant of the fifth Lord N., and was born in London, 10th August 1782. He entered the army in 1794, and was present at the battle of Coruffa. Subsequently he served through the Peninsular War, being severely wounded in several battles. In 1818 he was appointed Governor of Cephalonia, one of the Ionian Islands; and in 1841 Commander-in-Chief of the Bombay army. In this latter capacity it became his duty to effect the conquest of Scinde (q. v.), though he ever disapproved of the political consequences, which that conquest involved. The battle of Meeanee (q. v.) is one of the most brilliant actions in the military annals of the British in India. After the surrender of the Ameers of Scinde, Sir Charles N. was nominated the first civil administrator of that province, on which, amongst other benefits, he conferred the establishment of the port of Kurrachee. In 1849, by the unanimous voice of the British nation, he was called to the command of the Indian army, on the arrival of the news of the disasters of the second Sikh War; and he left England on a day's notice to take up that post. However, before his arrival in India, the victory of Gujerat had concluded the war. Owing to a difference with the Governor-General, Lord Dalhousie, he resigned in 1851, and returned to England. He died at Oaklands, near Portsmouth, 29th August 1853. A man of brilliant and daring genius, of great personal valour, with a passionate humanity and sense of justice, he was supremely fitted to subdue disorder, to inspire his enemies with terror, and his troops with confidence and admiration. The chief defect in his character was a certain rash and irritable jealousy, which at times brought him into fiery collision even with the ablest Indian officials. A statue has been erected to his memory in Trafalgar Square, London, the bulk of the cost of which was subscribed by private soldiers.—(3) **Sir William Francis Patrick N.**, brother of the preceding, was born at Castletown, in the county of Kildare, December 17, 1785, entered the army (1800), and obtained his captaincy (1804). He was present at the bombardment of Copenhagen (1807), and at seven of the great battles in the Peninsular War (1808-14), being wounded at Almeida and Casal Nova. He became major (1811), lieutenant-colonel (1813), colonel (1830), major-general (1841), lieutenant-governor of Guernsey (1842), and lieutenant-general (1851), having been knighted in 1848. He died at Clapham, February 12, 1860. He wrote a *History of the War in the Peninsula* (6 vols. Lond. 1828-40), in which he was assisted by his wife, a niece of Charles James Fox, and for which Wellington and Soult furnished materials; *Conquest of Scinde* (Lond. 1845); *Administration of Scinde* (1851); *English Battles and Sieges in the Peninsula* (1855); and the *Life and Opinions of General Sir Charles James N.* (4 vols. 1857).—(4) **Admiral Sir Charles N.**, a grandson of Francis, the fifth Lord N., was born at Merchiston Hall, in the county of Stirling, March 6, 1786, and was educated at the High School of Edinburgh (1793). He entered the navy (1800), was promoted lieutenant (1805) and commander (1807), had his thigh broken in an action with a French corvette (1808), captured Fort Edward at the siege of Martinique, and displayed the utmost gallantry and seamanship in a running fight with the *D'Hanpault* (1809). Created post-captain, but put on half-pay, he attended lectures at the University of Edinburgh; and then, 'unwilling to be idle,' joined Lord Wellington's army in Portugal, and was wounded at Buaco (1810). Commander of the *Thames* (1811), and of the *Euryalus* (1813), he served with Gordon in the 'unparalleled' enterprise up the Potomac (1814), was made a C.B. (1815), and being paid off, married a Mrs. Elers, a widow with four children. After a tour in France, Italy, and Switzerland, N. settled at Paris (1818-27), where he sunk all his capital in an unfortunate steamboat speculation, and in 1829 was appointed to the *Galatée*. Under the *nom de guerre* of 'Don Carlos de Ponce,' he took command of the Portuguese Constitutional fleet (1833), and sailed in quest of the Miguelites, whom he defeated off Cape St. Vincent (July 5) with three frigates, a schooner, and a brig, capturing two sail-of-the-line and two frigates. Created full admiral and Viscount Cape St. Vincent, he set himself to the fruitless task of reforming the Portuguese Navy, and co-operated in the land campaign which terminated in the Convention of Evora (May 26, 1834) and the establishment of Donna Maria on the throne of Portugal. Returning to England, N. was appointed (1838) to the *Powerful*, on the Levant station, and in 1840 received orders to

dispossess Mehemet Ali (q. v.) of Syria, and re-establish the authority of the Sultan. Landing, he took Sidon (September 25), and defeated Ibrahim Pasha at Boharsef (October 10). Next at sea, he led the van in the attack on Acre (November 4), and assumed (November 21) the command of the fleet engaged in the blockade of Alexandria, which he ended by the Convention of November 27, 1840. On his return home, N. was created a K.C.B., presented with the freedom of the City of London, and elected member for Marylebone (1841). As Rear-Admiral (1846), he commanded the Channel Fleet (1847-49), and on the outbreak of the Crimean War (1854) received the command of the Baltic fleet. With ill-manned ships and a total lack of gunboats and pilots, tied hand and foot too by red tape, N. accomplished little beyond the capture of Bomarsund (August 16), and on his arrival at Portsmouth (December 22) was ignominiously deprived of the command, while his applications for a court-martial remained unheeded. He refused the Grand Cross of the Bath (1855), but in the same year was returned to Parliament for Southwark. He visited St. Petersburg (1856), laboured successfully for navy reform (1857-59), and died at Merchiston Hall, his seat in Hampshire, November 6, 1860. N. was author of *An Account of the War in Portugal* (2 vols. Lond. 1836), *The War in Syria* (2 vols. Lond. 1842), *The Navy: Its Past and Present State* (Lond. 1851), and other works. See his *Life*, by his step-son, Major-General Elers N. (2 vols. Lond. 1862).—(5) **Robert Cornelis, Lord N. of Magdala**, one of the ablest of living English generals, was the son of an Indian officer, and was born in Ceylon 6th Dec. 1810. He entered the Bengal Engineers in 1826, first distinguished himself in the Sikh campaigns, especially at the siege of Mooltan (q. v.); and subsequently, in a civil capacity, planned and executed the roads by which the newly-acquired province of the Punjab was held. During the Mutiny of 1857 he was conspicuous at the sieges of Delhi and Lucknow, and was in command at the engagement of Powri, for which he was made K.C.B. He then served in the Chinese War, and from 1865 to 1876 was successively Commander-in-Chief of the Bombay and Bengal armies. In the former capacity he conducted in person the successful Abyssinian expedition, being the first engineer officer in British military history who has been intrusted with such an important command. In 1868 he was created a peer, with a pension of £2000 to himself and his next heir-male. Lord N. is now (1877) Governor of Gibraltar.

Napier's Bones, the name given to an invention of Napier of Merchiston, by which the operations of multiplication and division might be facilitated. The more important discovery of Logarithms (q. v.), however, rendered their use very limited; and now they are merely historic relics.

Naples, Kingdom of (Ital. *Sicilia Citeriore* or *Dominj di quâ dal Faro*), the continental part of the Kingdom of the Two Sicilies, comprised all Italy S. of the river Tronto in the E., and Capo Circello in the W. Area, 3,475 sq. miles; pop. (1851) 6,612,892. This territory, anciently inhabited by Samnites, Marsi, Lucanians, Brutii, Campanians, and the Greek colonists of Magna Græcia, became a Roman province (272 B.C.), and on the fall of the Western Empire (476 A.D.) was conquered by Odoacer, whose power in turn gave way before the invasion of the East Goths under Theodoric (489). Annexed by Belisarius and Narses to the Byzantine Empire (535-553), it was governed by seven dukes appointed by the emperor, and subject to the Exarch of Ravenna. The Lombards founded the duchy of Beneventum (571), but the maritime towns remained Greek, and from the close of the 8th c. were ruled by a Patricius, resident in Sicily, whence the phrases 'Two Sicilies' and 'Territories on this side the Strait.' The conquests of the Saracens (842) and the reconquests of the Greeks (890) were wrested from both by Norman adventurers, headed by the sons of Tancred of Hauteville. Robert Guiscard, receiving investiture of present and future acquisitions as a fief of the Holy See (1057), established the duchy of Apulia, Calabria, and Sicily, which under Roger II. became the feudal Kingdom of the Two Sicilies (1139). On the death of Guillaume II., the last legitimate member of the Norman line, in 1189, the Emperor Heinrich VI., his son-in-law, made himself master of the kingdom. It remained with the Hohenstaufens till 1266, when Charles of Anjou, defeating Manfred at Benevento, and beheading Konradin (1268), founded the Angevin dynasty. The Two Sicilies, severed by the Sicilian Vespers

(1282), were reunited under Alfonso V. of Aragon (1442), but again separated at his death (1458), N. falling to his natural son Ferdinand I. In 1495 it was conquered by Charles VIII. of France, and in 1501 by the united forces of Louis XII. and Ferdinand the Catholic, the latter expelling the French in 1504, and forming the Two Sicilies into a Province of Spain. The central episode of the Spanish rule was Masaniello's insurrection (1647). The Treaty of Utrecht (1713), terminating the War of the Spanish Succession, apportioned Sicily to Savoy and N. to Austria; but by the Peace of Vienna (1738), the Two Sicilies (reunited in 1720) were ceded to a younger son of the Bourbon Philip V. of Spain. He ascended the throne as Charles I., but himself becoming King of Spain (1750), vacated it to his third son, Ferdinand. The entrance of the French Republicans (1798) and the erection of the Parthenopean Republic were followed by a loyalist rising of the *lazzaroni* under Cardinal Ruffo and the return of the king, whose vindictive and reactionary policy of the next six years evoked Napoleon's manifesto: 'The dynasty of the Bourbons in N. has ceased to rule.' The reigns of Joseph Bonaparte (1806) and Murat (1808-15) were a period of savage guerilla warfare between the French and the Calabrian brigands, but during them began an intellectual movement, only fully developed some thirty years later, which would never have arisen under the numbing despotism of the Bourbons. After Ferdinand's restoration by the Congress of Vienna, N. was virtually a dependency of Austria. The liberal constitution won by the Carbonari in 1820 was overthrown by an Austrian invasion suggested by Ferdinand himself. Francis I. (1825-30) established the Swiss Guards, with whose aid Ferdinand II. (1830-59) withdrew in 1848 the liberties granted four months before, and strove to reduce Sicily to obedience by bombarding Messina. Shortly after the accession of Francis II. a law of the Swiss Confederation reduced these troops to 800 men; the National party at Turin seized the opportunity; Garibaldi's landing at Marsala (May 11, 1860) was followed by a series of unbroken successes; Francis, finding concessions useless on the part of a king who in twelve months had arrested 5000 *attendibili* ('suspects'), and seeing himself deserted by his followers, sailed for Gaeta (September 7); and on October 21, 1860, the Two Sicilies were declared by the vote of the people—1,742,320 ayes against 10,769 noes—to be henceforth a part of the kingdom of Italy, one and indivisible. Victor Emmanuel made his entry into Naples, November 7; and Gaeta capitulated, February 13, 1861. See Camera, *Annali delle due Sicilie* (Nap. 1841); Reuchlin, *Geschichte Neapels während der letzten 70 Jahre* (Nordl. 1862); and Di Sivo, *Storia delle due Sicilie dal 1846 al 1861* (Rome, 1863).

Naples (N. *Napolis*; Ital. *Napoli*), the largest city of Italy, and one of the most picturesquely situated cities in the world, extends for some 3 miles round the N. side of the famous Bay of N., rises on the face of several low hills, and is divided into two unequal parts by a ridge, which is marked by the heights of Capodimonte, S. Elmo, and Pizzofalcone, and terminates in the rocky promontory supporting the Castello dell' Ovo. From the bay it has a singularly beautiful appearance, its clusters of high and narrow houses, with their flat roofs and their countless balconies, standing out boldly against the hilly background, relieved here and there by luxuriant gardens and tree-shaded terraces. From the heights above the prospect is fairer still, stretching away across the purple waters of the bay to Ischia and Capri, and the shining points of Castellamare, while it is confined landwards by the tragic cones of Somma and Vesuvius. On the other hand the interior of the city is disappointing on account of its mean domestic architecture, its narrow and dingy streets, and its dearth of handsome public buildings, while it is rendered distasteful by the incessant clatter of vehicles, braying of donkeys, shouting of hawkers, and importunities of drivers, guides, and beggars. Still above the commonplace din occasionally rises the shrill song of the improvisatore, and the light-hearted crowds that for ever swarm in the streets and present a quickly shifting study to the artist, are interesting at once for their rich variety of costumes, their facility of gesture, and their deft use of the Neapolitan dialect, which is a mixture of Italian and Spanish, and *par excellence* the language of badinage. Thousands of visitors are annually attracted hither by the delicious climate, no less than by the beautiful situation, and quite a modern town has sprung up for their accommodation on the W. side of the city

proper. Here the gay Riviera di Chiaja, the Rotten Row of N., skirts the bay, flanked on one side by the Villa Nazionale, and on the other by fine hotels and other buildings. The Villa Nazionale, the principal garden and promenade in N., is beautifully laid out with orange, acacia, and myrtle groves, and contains several palms and a grand avenue of oaks. Adjoining it is the 'Zoological Station,' established chiefly by the munificence of Dr. Dohrn, the German naturalist, in connection with which an aquarium was opened in 1874. In the old part of the city the main street, the Toledo (officially since 1870 the Via di Roma), extends nearly $1\frac{1}{2}$ miles from N. to S., and presents a busy scene at all hours. There are many fine public squares, of which the principal are the Piazza St. Caterina, Dello Spirito Santo, and Di Plebiscito, the Cor-o Vittorio Emanuele, and the Piazza del Mercato. Among the chief secular buildings are the Palazzo di Capodimonte, on the height of the same name, begun by Charles III. in 1738, but not completed till 1834-39; the Palazzo Reale ('royal palace'), begun under the Viceroy Count di Lemos in 1600, and restored 1837-41; the Museo Nazionale, which was the home of the university from 1615 to 1780, and which now contains the Farnese collections from Rome and Parma, and is unrivalled for Pompeian antiquities, bronzes from Herculaneum, and other art objects; the poorhouse (Albergo dei Poveri), begun 1751, and capable with its dependencies of accommodating 5000 persons; the Palazzo Gravino (1500), now the General Post Office, and the finest building of the kind in N.; and the Teatro San Carlo, founded 1737, one of the largest opera-houses in Europe, containing six tiers of boxes. N. can boast of few Græco-Roman remains, but of Middle Age construction it has, besides several churches, five forts—Castello St. Elmo, Dell'Ovo (named from its 'egg' shape), Nuovo, Del Carmine, and Capuano—and two gates, Porta del Capuano and Carmine. Many of the churches are rich in paintings. The principal are the cathedral of St. Gennaro (see JANUARIUS), founded 1272, but now completely modernised, and the churches of St. Domenico Maggiore, a Gothic structure of 1285, but altered in 1850-53; St. Filippo Neri, built in 1592, and overloaded with ornament; St. Maria del Carmine, modernised in 1769, and containing the tombs of Konradin and Friedrich of Austria; and Santa Chiara, dating from 1310, but partly rebuilt in 1752. The university, founded by the Emperor Friedrich II. in 1224, is one of the oldest in Europe, and possesses five faculties, twenty-five professorial chairs, a large library, and valuable scientific collections. The monastery connected with the Church of St. Severino e Sossio contains the archives of the former kingdom, which are among the most valuable in the world, comprising 40,000 parchment MSS. and documents relating to the Norman, Hohenstaufen, Anjou (alone 380,000 in number), and Spanish periods. Beside an observatory and botanic gardens, N. has a music conservatory, founded in 1537, which has sent forth many eminent composers. The catacombs, parts of which date from the pagan era, are of great extent, and surpass those of Rome in the width and height of their passages. Adjoining the ancient Molo of 1302 are the extensive harbours—on the right the Porto Militaire, or government harbour, and on the left the Porto Mercantile. The former, 5 fathoms deep, is protected by a strong breakwater 429 yards long, and is a frequent station of the Italian ironclads. N. manufactures some silks, linens, and woollens, but the specialties are gloves, gold wares, musical instruments, ornaments in coral, tortoise-shell, and lava, artificial flowers, copies of Etruscan vases, and macaroni. There is an extensive trade, chiefly in wine, oil, almonds, and sulphur. In 1875 the imports amounted to £6,428,656, and the exports to £1,609,142. Of the imports, £2,367,586 worth were from Great Britain; of the exports, £1,017,537 went to France and Algeria. The climate is more equal than that of Rome and Florence, the mean temperature being 63°, or ranging from 27° to 104°. The coldest weather is from 12th December to 12th March; from April to September the sky is generally bright and cloudless. Spring water is neither good nor abundant, and the new water-works now (1878) in progress will not be completed for some four years. Cisterns have in modern times taken the place of the ancient aqueducts. Pop. (1874) 415,549. N. was a Greek colony, and was called *Neapolis* ('new city') to distinguish it from the neighbouring *Parthenope*, known subsequently as *Palaopolis* or 'old city.' After the Roman Conquest N. was allowed to retain its municipal freedom and Greek constitution. Lucullus and Virgil were among the many

Romans who resided here. Stormed by Belisarius in 536 AD., and again by the Eastern Goths in 543, N. was for only a brief period under Byzantine supremacy. Subsequently its 'duca' or doge maintained its independence against the Lombard princes, but after a long siege it succumbed to the Normans in 1130. It was made the capital of the kingdom by Charles I. of Anjou, and among its later benefactors were Ferdinand I. of Arragon, the viceroy Don Pedro de Toledo, and Charles III. of Bourbon. Although so bountifully favoured by nature, N. has rarely attained even a transient reputation in politics, art, or literature.

Naples Yellow, a valuable yellow pigment, the basis of which is antimony, equally useful in oil painting, and for enamel colour, and porcelain painting. Chrome yellows are now much used as a substitute for N. Y.

Napoleon Bonaparte, Emperor of the French, second son of Charles Bonaparte, an Italian lawyer, who, in 1771, formed one of 400 Corsican families constituted a nobility by Louis XV., was born at Ajaccio in the island of Corsica, 15th August 1769. Through the influence of the Comte de Marbeuf N. was admitted in his tenth year to the military school at Brienne, where he remained until 1784, and it was afterwards remembered of him that he was shy and obstinate, though he made rapid progress in mathematics, history, and geography. In 1785, having spent a year at the Royal Military School of Paris, he was appointed sub-lieutenant of an artillery regiment, and the outbreak of the Revolution found him stationed at Valence. His sympathies at that time were democratic, and in a visit paid to the island of Corsica in 1792 N. opposed General Paoli in his scheme of abandoning the Convention and allying himself with England. Obligated to escape from Corsica, N. resided for about a year at Marseilles, where with the rank of captain he assisted in a cannonade of the town federalists. At the siege of Toulon he dealt his first stroke in military strategy (December 1794), the surrender of the town being due to a suggestion made by him after the failure of other attempts. The Committee of Public Safety rewarded him by a generalship of brigade, with a commission in the army of the S., from which he was shortly cut off on suspicion. He was on the point of offering his services to the Ottoman Porte when the necessities of the Convention suggested him as a suitable commander for the troops in its service. On the 4th of October 1795 he vindicated his right to the position by routing the National Guard in their attempt upon the Tuileries. He was then appointed general of division, and having married Josephine, widow of Vicomte de Beauharnais (March 1796), he set out to take the command of the army in Italy. His troops numbered about 35,000 men, but their clothes and shoes were worn out, there was little money to buy them with, and they had to forage for their food. N. had only received 2000 louis in money wherewith to meet immediate expenses, and the scandals which attach to the department of his commissariat were due to the fact that it was superintended by a speculative contractor. But the men were young and hardy, having already a large experience of war among the Pyrenees and Alps; and among their generals were Masséna, Augereau, Laharpe, Serurier, and Berthier, each of them with special qualifications for the service. At first N. was regarded with some jealousy. 'He was,' says M. Thiers, 'considered far too young to command the army. Of a short, slight figure, without any peculiarity in his appearance beyond Roman features and his steady and piercing eye, there was nothing in his person or past life that seemed remarkable. He was received without any great show of attention.' His first address, however, filled the army with enthusiasm. 'Soldiers,' said he, 'you are ill-fed and almost naked. The government owe you much, but can do nothing for you. Your patience, your courage, do you honour, but procure you neither benefit nor glory. I am going to lead you into the most fertile plains in the world; you will there find large cities, rich provinces; you will there find honour, glory, and wealth. Soldiers of Italy, would your courage fail you?' It is the first of a series of harangues delivered by N. at hazardous moments, and in them French criticism has discovered so much literary point, force, and eloquence, as to raise them to the rank of creative genius among the productions of literature. Between the months of March 1796 and December 1797, with a force which at the outset he found in a condition of utter disorganisation, N. faced and destroyed five powerful armies. He was victorious at

Voltri, Montenotte, Millesimo, Dego, Ceva, Vico, Mondovì, and Cherasco, after which the army of Beaulieu was scattered and the Piedmontese separated from the Austrians. Before the end of June many of the chief cities as far S. as the States of the Church were plundered, tribute to the extent of 50,000,000 francs was exacted, and a committee of *littérateurs* selected for transference to France what was best from the artistic treasures of the country. The army of Marshal Würmser, numbering 70,000, was next encountered and worsted at Castiglione, Roveredo, and Bassano by September 1796. Marshal Alvinzi and General Davidovich by the 14th January 1797 had been put to flight at Arcola, Rivoli, and Mantua, whilst the Archduke Karl with an army poorly equipped was chased from the Tagliamento, beaten at Ungmarkt, and permitted to make peace at Leoben (April 17). On the 17th October 1797 this peace was ratified by the Treaty of Campo-Formio, under which Venice was attached to Austria, whilst the Netherlands and Lombardy went to France. Throughout the course of those campaigns N. proved that his administrative was as strong as his military genius. The success of the French arms was, however, materially assisted by the social condition of Italy. Touched with the revolutionary spirit, the population of the country turned against their rulers, overthrew their governments, and welcomed the French as the pioneers of Republican freedom. They had soon to learn that it was not Italian but French republics that N. desired to set up. Before returning to Paris he had organised the Cisalpine Republic, which included Lombardy, Parma, Modena, Papal States of Bologna, Ferrara, Romagna, and the Venetian territory as far as the Adige; and the Ligurian, Cispadane, and Tiberine Republics, with Genoa, Bologna, and Rome as their capitals. On the 5th December 1797 he returned to Paris, and at once became the darling of the populace. On the 10th December he was the hero of a triumphant *fête* given in his honour by the Directory at the Luxembourg, and in the severe simplicity affected by N. his contemporaries subsequently called to mind that they felt 'the indescribable sensation of genius and authority which he impressed upon the imagination.' He lived in a plain and unpretending way in the Rue Charlevoix, and amidst the festivities and pomp 'he appeared simple and affable, but constrained, almost insensible to pleasure, seeking among the crowd the useful and celebrated man, in order to converse with him on the art or science in which he was known to excel.' In a few months he had not only made the acquaintance but earned the esteem of the most distinguished *savants* of France, and was elected to a vacant place in the Institute. But the Directory soon found fresh work for him to do. Being at peace with the rest of Europe it was determined to strike a blow at England through Egypt. It was one of the sayings of N. that 'great names are only made in the East,' and dreading the stagnation of civil life, he threw himself with animation into the fulfilment of an enterprise which had long occupied his dream. In addition to the military equipment, he associated with himself scientific men, artists, engineers, draughtsmen, and geographers. Monge, Berthollet, Fourier, Dolomieu, Desgenettes, Larrey, and Dubois were among the number. N.'s design was, by the conquest of Egypt, either to make it a colony whereby he could turn the Mediterranean into what he called 'a French lake,' or to use it for establishing a navy in the Red Sea, by which the English settlements in India might be harassed, if not destroyed. Preparations were conducted with the utmost secrecy, and on the 19th May 1798 a fleet sailed from Toulon. On the 1st of July N. was before Alexandria with his army of 30,000 men, having reduced Malta in his passage across the Mediterranean. Alexandria fell on the 4th, and Cairo on the 24th July, the march between the two cities being distinguished by the famous address of N. in sight of the Pyramids, 'Soldiers! remember that from these Pyramids forty centuries contemplate your deeds.' At once he commenced to consolidate the French power in Egypt. He established tribunals of commerce in the four leading cities, and encouraged industrial enterprise in the shape of mills and manufactories. A police was organised in the different towns. Mamelukes and Arabs were entitled, by special decree, to serve in the French army. An Institute of Egypt was founded, and scientific *séances* were held from time to time, the notes and observations of the corps of learned men who accompanied him being then submitted for consideration. Alliances were struck up with the Bey of Tripoli and other neighbouring potentates,

and N. even sent an emissary to Mysore in order to rouse the Sultan into rebellion against the English government. The Battle of Aboukir (August 2) annihilated the French fleet, but N. pursued the conquest of the country, put down with rigour a revolt in Cairo, marched to meet the Turks in Syria, taking El-Arish, Gaza, and Jaffa (March 1799), but was checked at Acre, where Djézzar Pasha and Sir Sydney Smith opposed him with a mixed force of Turks and English. At Aboukir (25th July) N. retrieved his position by driving an Ottoman army into the sea, and next month he set sail for France, his arrival at Fréjus (October 9) being made the occasion for the most extravagant manifestations of joy. Allying himself with Sieyès, on his return to Paris N. brought about the abolition of the Directory and became the chief of the consular commission, with the title of First Consul, taking up his official residence (19th February 1800) at the palace of the Tuileries. By the new constitution, which was mainly the result of the meditations of Sieyès, N. practically became Dictator of France. Representation, however, by the people, was reduced to the merest name, as they were only allowed to vote for the notables of the Commune, who, in turn, elected one-tenth of their number notables of departments, from which a tenth were re-elected as notables of France, and from them again were nominated the Legislative Assembly. At once the firm stamp of N.'s personality was felt in all the public departments; prefects, sub-prefects, and mayors were established throughout the country; local courts and the higher tribunals of justice were rearranged on a new basis, and the administrative system which survives to-day was for the most part brought into existence at that time. But a new ambition had begun to take hold of him. 'Well, Bourrienne,' he observed to his secretary on the day after his transference to the Tuileries, 'here we are at the Tuileries! and we must now stop here.' In May he was again in the field, conducting 35,000 men across the Alps in a brilliant movement which brought him, as he planned, on the rear of the Austrian lines. He entered Milan on June 2, and on the 14th was fought the battle of Marengo, in which the Austrians were defeated. N. regained thereby all that had been lost in Italy during his absence in Egypt. After the battle of Hohenlinden, however, the Peace of Lunéville (February 1801) was signed with Austria, and at Amiens (March 27, 1802) a treaty was made with England. By affirmative suffrages exceeding three millions and a half N. was proclaimed (2d August 1802) Consul for life. During this period he showed his consummate capacity for administration by the unflagging industry with which he turned his attention to every branch of civil life. Agriculture, commerce, manufactures, education, public works, and law were each passed in review. To his initiative was due the execution of the *Code Civil*, which reduced to uniformity the heterogeneous mass of legal customs and traditions. At the same time, though he was probably indifferent to religion, by a Concordat with the Pope he restored the Catholic Church as the religion of the majority of Frenchmen. He took that step against the advice of his colleagues, supporters, and friends, who had all been concerned in the deposition of the old system of worship. It was represented to him that he was laying at the feet of Rome the dignity of his government. N. declined to maintain an attitude of indifference on the ground of the utility of putting an end to religious differences and divisions. He drew up a scheme of reconciliation between the French Republic and the Roman Church. There was to be no longer a clergy endowed with landed property. They were to receive their incomes from the State, and to devote themselves solely to their professional duties. Regulations of places of worship were to be transferred to the State, and clerical jurisdiction to the Councils of the State. The new clergy was to be formed from every ecclesiastical party, and the bishops to be nominated by the First Consul. In 1802 N. became President of the Italian Republic and 'Grand Mediator of the Helvetic Confederation.' On the 13th of May 1803 the English ambassador left Paris, and N. was again at war with England. A flotilla of 2000 sail was collected for the purpose of invading England, and a line of camps stretched from Havre to Ostend. During these preparations the life of N. was threatened by a conspiracy of Royalist refugees, which, on the discovery of the plot, induced him (20th March 1804) to hasten the secret execution of Duc d'Enghien, a step which he afterwards vindicated as 'necessary to the safety, the interests, and the honour of the French people.' By this time N. had made up his mind to change the

form of government. 'Fouché,' writes M. Thiers, 'in the ardour of his zeal made himself the spontaneous agent of the change which was preparing. He accosted the First Consul, whose secret wishes he had already divined, represented to him the need of taking a prompt and decided part, and the urgent necessity for terminating the anxieties of France and putting the crown upon his head, thus consolidating definitively the results of the revolution. He showed him how all classes in the nation were animated by the same sentiment, and impatient to proclaim him emperor of the Gauls or of the French, as was most agreeable to his policy and taste.' Through secret agents Fouché was able to spread reports in the English journals to the effect that peaceably-disposed people in France wished for an hereditary sovereignty. The French papers reproduced these articles and the signal was given. It was soon settled that the First Consul should be proclaimed emperor, that male should succeed male in the order of primogeniture in his family, and that in default of adopted descent the transmission of the crown be permitted in the collateral line of his brothers Joseph and Louis. N.'s brothers and sisters received the rank of princes and princesses, the former with a million francs per annum each. The plot was thus made the pretext for a declaration in behalf of imperialism, and on the 15th May 1804, by an 'organic senatus consultum,' N. was elected to found a dynasty. On the 2d December 1804 he crowned himself in presence of the Pope; on the 26th of May 1805 he assumed at Milan the Iron Crown (q. v.) with the title King of Italy. The year 1805 was distinguished by a fresh European coalition against N., but by October he had removed his army from Boulogne to the Rhine, forced the Austrian general to lay down his arms at Ulm, and entered Vienna (13th November). On the 22d he crossed the Danube, and after some days of masterly manœuvring he gained the battle of Austerlitz (2d December) over an Austro-Russian force, the result of which was that the Venetian States, the Tyrol and Suabia, were alienated from Austria. In October 1806, Prussia, goaded to indignation by the studied insults of N., put an army of 150,000 men into the field under the Duke of Brunswick. N. met and overwhelmed it with defeat (October 14) at Jena, entered Berlin (19th), gave up its galleries and museums to plunder, and issued a decree promulgating 'the Continental system,' by which all trade with England, under heavy penalty, was interdicted. Following up his victory, N. directed his next movements against Russia, but was defeated (January 1807) at Eylau, a defeat which he retrieved (June 14) at Friedland. A treaty was then signed at Tilsit, and by one of its conditions Jerome Bonaparte became King of Westphalia. Joseph had already been appointed King of Naples, and Louis King of Holland. On his return to France, encouraged by the universal worship of the people, he systematised his tyranny with more compactness, abolishing the liberty of the press, annulling the Tribunal, establishing a system of education whose highest aim was to turn out conscripts. The year 1808 witnessed his ruinous interference with Spain and Portugal in order to enforce 'the Continental system.' By the 14th of December N. entered Madrid in triumph, the reigning dynasty was deposed, and his brother Joseph abandoned the crown of Naples for the new royalty. But on the 3d of January 1809 N. was called away owing to a fresh rupture with the Emperor of Austria, who determined to strike a blow at France when her forces were scattered. On the 22d of April N. encountered and defeated the Austrians at Eckmühl, was himself defeated at Aspern (May 23), but triumphed at Wagram (July 6). The Emperor Francis was compelled to acknowledge the sovereigns of N.'s creation, and to adopt the prohibitory system of commerce. Besides, at the solicitation of N. he handed over his daughter Maria Louisa, with whom, the Empress Josephine being divorced, a marriage was celebrated at the Tuileries (April 2, 1810). For two years events had a calmer aspect, though N., by his infatuation in behalf of a prohibitory traffic, annexed Holland, the Hanseatic towns, and the N. German coast between Ems and the Elbe, rousing thereby the hostility of Sweden and Russia, who at length declared war (January 1812). With an army of 450,000 men of different nations N. set out for Russia in July, drove his enemies from Smolensk (August 17), caused them to retire from Borodino (September 11), and from Moscow a week later. Famine, frost, and snow fought for the Russians, and N. was compelled to retreat (19th October), his army reduced to about a fourth of its original size. He was in Paris on the 18th

December, having left Murat to conduct the retreat to a conclusion. In the spring of 1813, by a stringent conscription, he had an army at his disposal of 350,000 men. Between May and August he conquered in the fields of Lützen, Bautzen, and Dresden, but a great day of reckoning came on the plains of Leipsic. The allies confronted his 140,000 men with 230,000. He tried to negotiate an armistice on the night of the 16th October, but his attempt failed; he was worsted in battle, and on the 17th he commenced his retreat towards France. Meanwhile the campaign in Spain had been disastrous for the French generals, and Joseph was no longer king. N. demanded from the Senate a fresh levy of 300,000 men, which was granted. But the armies of Austria, Silesia, and Russia closed round Paris, and on the 31st of March 1814 defiled through the city, whilst the people cheered them as deliverers. *Assez de Bonaparte* was the general feeling. On the 2d of April the Senate decreed that N., by his violation of the rights and liberties of the people, had forfeited his throne. He signed the Treaty of Fontainebleau on the 11th, retaining under it the title of Emperor for life, with the sovereignty of the Isle of Elba and an income of 2,000,000 francs. But on the 20th of March 1815 he reappeared in Paris, awakened some of the old enthusiasm, gathered round him an army of 125,000 men, and led them to the Flemish frontier to do battle with the allies. On the 16th of June he repulsed the Prussians at Ligny, but on the 18th was fought the battle of Waterloo, the result of which shattered the cause of N. for ever. Again his forfeiture of the throne was decreed, with the added penalty of banishment. Driven to the last extreme, N. finally delivered himself up to the captain of an English frigate, and Great Britain, with the sanction of the allies, banished him to the island of St. Helena, where he remained in restless misery until death took him off, 5th May 1821. His body was interred with great pomp (15th December 1840) beneath the dome of the Church of St. Louis, at the Hôtel des Invalides, Paris. During the course of his life N. wrote much, but his connection with literature was more an accident of his position than anything else. M. Gerviez has said, however, that he was as capable of painting as of gaining battles, and does not hesitate to compare some of his descriptions with those of Caesar, and his military harangues with the orations of Mirabeau. Among the works of his youth are *La Calotte*, a pamphlet setting forth the rules of a regimental society; *Lettre à M. Matteo Buttafuoco*, in which, with great force and exuberance of language, he attacks a Corsican deputy for his treasonable leanings to aristocracy; *Histoire de la Corse*, concerning which Mirabeau is reported to have said that 'it seemed to announce a genius of the first order'; *Le Souper de Beaumais*, which contains a defence of the Convention and its committees. By far the most important of his contributions are his letters and reports, scattered through different volumes. The *Collection Générale* and *Correspondence Inédite*, though they require to be read sceptically, contain the best of them. N. not only inspired the press, but frequently wrote for the *Moniteur Universel*, which he chose as the organ for giving expression to the information and views he desired to have in general circulation and belief. M. Thiers says his articles were easily detected at the time for their incomparable vigour. N. certainly caught some of the fire of his own actions, and expressed it in his prose, but when the qualities of rapidity and precision, which occasionally rose into a strain of eloquence, are mentioned, everything has been said to which his work in that line is justly entitled. History, ancient or modern, produces no figure whose claims to greatness on the score of military genius surpass those of N. He had every quality essential for command. His knowledge of strategy was profound, and it was supplemented by a creative impulse on the field which devised surprises and suggested combinations unknown to men who had according to precedent and routine. He was of undaunted courage, of immaculate coolness, fertile beyond measure in resource, ever prepared against the unforeseen accidents of battle, and seldom, in consequence, taken by surprise. Nor, though indifferent to human life, was he actively cruel in disposition. In administration his ability was conspicuous, and in all departments of it he showed an infinite capacity for taking pains. Up to the period of his assumption of the First Consulship his aims were in harmony with the best aspirations of the Revolution. Anarchy he always hated, but the reorganisation of society on a democratic basis was one of the articles of his earlier creed. N. was morally ruined by the outward splendour of his own career. He became

a portentous tyrant, an enemy to his own country and the best interests of Europe, and the world breathed freely for the first time for many years when his illimitable ambition landed him at last on the rock of St. Helena.

The literature to which N. has given rise would form a vast library. It is written in every European tongue, and embraces every feature of his policy, every circumstance of his career, and every aspect of his character. It is impossible even to faintly indicate its extent or variety. N.'s own *Œuvres* first appeared at Paris in 6 vols. 1821-22. In connection with these may be mentioned Generals Gourgaud and Montholon's *Mémoires pour servir à l'Histoire de France sous N., écrits à Ste-Hélène, sous la Dictée de l'Empereur* (8 vols. Lond. and Par. 1822-24), and the *Correspondance de N. J.* (15 vols. Par. 1858-66), published by command of Napoleon III. Among the innumerable memoirs written by those who knew or served the Emperor, we may specify those of O'Meara, Las Cases, Antommarchi, Hudson Lowe, Bausset, Durand, Bourrienne, Abrantes, Montholon, Masséna, Ney, Belliard, Marmont, Miot, and Bignon. Of histories proper, in which N.'s life forms part of the history of his time, the chief works in French are those of Jomini (q. v.), Laurent, Thibaudeau, Saint-Hilaire, Michaud, Regnault, Thiers (q. v.), and Lanfrey; in English, Scott (q. v.), and Hazlitt (q. v.); in German, Kolb, Schlosser, Becker, and Roth. The latest and most iconoclastic biographer is Pierre Lanfrey, whose *Histoire de Napoleon Ier.* (5 vols. Par. 1867-76) is the most formidable assault on the character of N. ever made in or out of France.

Napoleon III. (Charles Louis Napoleon Bonaparte), Emperor of the French, was born at the Hôtel de Queen Hortense, Rue Cérutti, Paris, 20th April 1808. He was the son of Hortense Eugénie Beauharnais, wife of Louis Napoleon, third brother of the First Napoleon. At the time of his birth, owing to the law of succession, which, in default of direct heirs male of the emperor, vested the crown in the families of Joseph and Louis, N. was at once regarded as the imperial heir. Fêtes were ordered to be observed in his honour throughout France, and on the 10th November 1810 he was baptized, the emperor and Maria Louisa acting as godfather and godmother. After the accession of Louis XVIII., Hortense, who had been separated from her husband in 1810, retired to Geneva, and it was at the castle of Arenenberg, near Lake Constance, that N. received his earliest education. At the Augsburg gymnasium he showed a distinct bias towards military study, and became a proficient in swimming, riding, and fencing. Joining the federal army of Switzerland as an officer, he pursued with enthusiasm the sciences of artillery and engineering. On the accession of Louis Philippe to the French throne, N. applied for permission to return to France, but his application was rejected. Along with an elder brother he then threw himself into the insurrectionary movement in Italy, was seized with a severe illness at Ancona, and driven back in disguise to France, from which he and his mother were ordered to depart. His brother died at Forlì, in Italy. In 1831 N. was in Switzerland, and was understood to have received overtures from the Poles to accept their crown and to lead their army, but with the fall of Warsaw the scheme came to an end. In July 1832, while quietly pursuing historical and other studies, the death of the Duc de Reichstadt, Napoleon II., made him the sole heir to the responsibilities of the imperial traditions. He accepted them with alacrity, and from henceforth his mind was dominated by the single determination that he should win back the throne to his house. His *Réveries Politiques* contained the fruits of his thoughts about this time, and in their development of the central idea that the republican and military aspirations of France could only be united in a Bonaparte, they reveal the keenness with which he was watching the rise of discontent at the government of Louis Philippe. During the next four years his literary activity was exhibited rhythmically in *Deux Mots*, and in prose of vigour and clearness in *Projet de Constitution*, *Considérations Politiques et Militaires sur la Suisse*, and *Manuel d'Artillerie*. In October 1836, N. thought the time was ripe for striking a blow in behalf of his dynasty. With the assistance of Comte de Persigny and Colonel Vaudrey he attempted, on the morning of the 30th, to raise the garrison of Strassburg, and being presented at the barracks suitably arrayed in a dress like the emperor's, he might have succeeded had it not have been for the prompt and vigorous action of Colonel Taillandier. He proclaimed N.

to be an impostor, turned the current of the enthusiasm, arrested and detained him at Strassburg till November 9, sent him to Paris, where, after brief imprisonment and trial, he was despatched to America. But by the 3d October 1837 he was back in Arenenberg at the death-bed of Hortense. The French Government then demanded the extradition of N. by the Swiss. The latter refused on the ground that he was a Swiss citizen; and had N. not voluntarily retired to England, the Republic would have supported its attitude by arms. In England N. continued his literary industry, and (1839) the *Idées Napoléoniennes* traversed the field of imperial organisation, and connected that régime with the revolutions and the sovereignty of the people. The order given by the French Chamber (May 1840) for the entombment of the remains of Napoleon I. at Paris influenced the imagination of N. so much that he planned a second invasion of France. On the 5th of August he embarked on board the *City of Edinburgh* with fifty-five followers, landed at Boulogne next day, unfurled the imperial standard, and was ignominiously beaten back. Being captured, he was tried before the Chamber of Peers, and after he had delivered an ingenious defence, he was sentenced to perpetual imprisonment in Ham, a fortress on the borders. For five years he was kept in durance, and he improved his compulsory leisure by contributing to the democratic press, and by writing several political and historical treatises. His *Extinction du Paupérisme* and *Fragments Historiques* are among the best known of these. By the assistance of Dr. Conneau, N. escaped from Ham (May 25, 1846), and again took up his residence in England. The abdication of Louis Philippe (February 1848) induced N. to hasten to Paris, where he offered his services to the Provisional Government, which not only declined his offer but desired him to return. He did so, but four constituencies elected him as their representative for the National Assembly. A majority decided that he should be allowed to take his seat, but N. executed a fine stroke of policy by placing his resignation in their hands in order that tranquillity might be restored. The sympathy of the country was at once enlisted on his side. In the month of September he was returned to the Assembly by four more constituencies, and on the 10th of December he was, through universal suffrage, elected to the Presidency by a majority over his opponents Cavaignac, Ledru Rollin, Raspail, Lamartine, and Changarnier of four million votes. There then commenced between the President and his Ministers and the President and the Assembly a struggle for repression on the one hand and dominance on the other. Crisis followed crisis, and N. by means of proclamations began to accustom the country to the idea that the Assembly were thwarting his best intentions. At last, however, the *coup-d'état* of December 2, 1851, cut short the connection between the President and the representatives. On the night of the 1st December decrees were posted throughout Paris dissolving the National Assembly, declaring a state of siege, and announcing:—'I no longer wish for an office which is powerless for good, but which makes me responsible for acts that I cannot hinder—chains me to the helm when I see the vessel rushing into the abyss.' These decrees were followed by the infliction of grave indignities upon the persons of the leading representatives, several of whom were imprisoned, whilst all had to submit to expulsion from the Assembly at the point of the bayonet. The Reds of Paris erected barricades, and fought the soldiery, who shed much useless blood by firing right and left into the windows of citizens unconnected with the rising. But the country sanctioned the act by confirming him in the Presidency with more than seven million votes, and in November of the ensuing year the Senate asked him to assume the title of Emperor. An appeal to the plebiscite in November 21st and 22d secured for him nearly eight million affirmative votes. N. married, 30th January 1853, Eugénie Marie, Countess of Montijo, and on the 18th March 1856 a son was born to them. The first fruits of the foreign policy of N. were seen in his attitude towards England, with which he made it an object of ambition to be on terms of friendship. From 1854 to 1856 the progress of the Crimean War cemented this friendship. In 1855 N. was enthusiastically received in England, and three years later the Queen repaid the visit in person. The Commercial Treaty was signed in 1860, and N. became the ally of England in the Chinese War. N. was successful in the Franco-Italian War (1859), but at the request of America was obliged to withdraw his troops from Mexico (1863), though he looked forward to a permanent tenure. In 1865-66 he published 2 vols. of an un-

finished *Histoire de Jules César*, designed as a vindication of Imperialism in politics. In 1870 N. was induced to embark upon the war with Prussia, which terminated in his downfall at Sedan, the overthrow of the Empire at Paris, and his exile in Camden House, Chislehurst, where he died January 9, 1873. His character has been estimated from widely-different points of view, but it is certain that on any theory he had an indomitable belief in his own destiny, was gifted with much practical sense, became unscrupulous through the pressure of circumstances rather than by natural inclination, and was sincere in his aspirations for the greatness of France. See Blanchard Jerrold's *Life of Napoleon III.*, of which the third volume appeared in 1877.

EUGÈNE LOUIS JEAN JOSEPH N., the Prince Imperial, born at Paris, March 16, 1856; accompanied his father to the seat of war in 1870, and at Saarbrück (August 2) received his 'baptism of fire.' After Sedan he escaped to Belgium, and crossing to Dover (September 6) was joined at Hastings by the Empress. He entered the Woolwich Academy (1872), attained his majority (1873), and is generally recognised as the head of the house of N.

Napoleon, Joseph Charles Paul Bonaparte, Prince, cousin of the preceding, second son of Jerome Bonaparte and Princess Frederika of Würtemberg, was born at Trieste, September 9, 1822. His youth was passed amidst feverish travel from Austria to Italy, Spain, and England, but he had some systematic education (1833-35) at Geneva and (1840) at Würtemberg. As Comte de Montfort he was allowed to visit Paris in 1845, when he immediately began to ally himself with the Extreme Left. Being ordered to retire, he did not reappear until 1848, was returned to the Assembly by the Corsicans, appointed Minister Plenipotentiary at Madrid (1849), created a prince of France with a seat in the Senate and Council of State, with the Grand Cross of the Legion of Honour, and the post of General of Division (1853), and commanded so ingloriously in the Crimean War that he earned for himself the title of *Fion-plon*. In 1855 he was President of the Imperial Commission of the Universal Exhibition, in 1858 chief of the ministry for Algiers, and in 1859 served without distinction in the Italian War. He married (January 30th, 1859) Princess Clotilde, daughter of Victor Emmanuel. A speech delivered in 1861 to the Senate against the Orleans family drew from Duc d'Aumale a challenge, which N. declined. The contempt universally expressed for him in military circles at this time made a trip to America a convenient change. In 1862 he represented France at the Great Exhibition at Kensington, and acted as President of the Commissioners for the Universal Exhibition at Paris of 1867. A speech delivered at Corsica lost him the imperial favour for a short time, but on regaining it he is understood to have influenced his cousin in the direction of a more liberal policy. When the Franco-German War broke out, N. was refused a command, and sent to Italy upon a confidential mission. On returning to France at its termination, he was ordered to the frontier, but was subsequently permitted to resume residence. He has devoted himself, without success, to rallying round him a new Bonapartist faction. At the October elections (1877) he lost his seat in the Constituent Assembly. N. is a man of extensive culture, is not without political ability, but is absolutely devoid of moral earnestness.

Napoleon d'Or, a French gold coin worth twenty francs, named after the Emperor Napoleon I.

Napoléon Vendée. See ROCHE-SUR-YON.

Napoléonville, or **Pontivy**, a town in N.W. France, department of Morbihan, in a fertile district, on the Blavet and the Canal from Nantes to Brest, 40 miles N.N.W. of Vannes by rail. It contains the castle of the dukes of Rohan, and the best cavalry barracks in France. Pop. (1872) 5136.

Na'poli di Roma'nia. See NAUPLIA.

Napu', a name given to the Javan Musk Deer (q. v.) (*Tragulus javanicus*), allied to the Kauchil or Pigmy Musk Deer (*T. pygmaeus*).

Naraingunje (= market of the Lord, i.e., Vishnu), a town in the district of Dacca, Bengal, British India, on the right bank of the Lakhmia river, just above its confluence with the Brahmaputra, 9 miles S.E. of Dacca, and 155 N.E. of Calcutta. Pop. (1872), with the suburb of Modungunge, 10,911. It has regular steam communication with Calcutta, and is an em-

porium of the jute trade, and for the through traffic with Assam, Cachar, and Chittagong. In the year 1876-77, the total exports were valued at £957,000, chiefly jute (£478,000) and rice (£138,000); the imports were valued at £1,338,000, including piece-goods (£324,000), salt (£184,000), raw cotton (£122,000), sugar (£95,000), and tobacco (£66,000).

Narbah, the capital of a native state bearing the same name in N.W. India, in political connection with the Punjab government, 1035 miles N.W. of Calcutta. It contains an old fort.—The state of N., which is somewhat scattered, lies mostly between Puttela and the British district of Loodiana; area, 804 sq. miles; pop. 226,155; revenue, £65,000; army, 1500 men. It was one of the Cis-Sutlej states founded by the Sikhs in Sirhind about the middle of the last c. For services rendered during the Mutiny of 1857 the Rajah of N. was rewarded with an accession of territory. His family is the head of the Sidhu Jat tribe.

Narbonne, a town of France, department of Aude, on the Robine branch of the Canal du Midi, 92½ miles E.S.E. of Toulouse by rail. It contains the 13th c. churches of SS. Just and Paul, an hôtel-de-ville (formerly the archbishop's palace), a museum, and a public library; has breweries, potteries, dye-works, manufactures of brandy, verdigris, cloth, and candles; and carries on a trade in honey, wines, oil, grain, &c. Pop. (1872) 12,590. The *Narbo Martius* of the Romans, N. was known to the Greeks in the 5th c. B.C., and was colonised by Licinius Crassus (B.C. 118). Under the emperors it rose to be the capital of Gallia Narbonensis, and numerous remains of antiquity attest its former grandeur. Though sacked by the Saracens (719), and by the Northmen (859), N. was still in the 12th and 13th centuries a city with 40,000 inhabitants, and concluded commercial treaties with Alexandria and Constantinople.

Narcissus, according to a Greek myth, was a son of the river-god Cephissus, and of the Thespian nymph Liriope. Handsome, but inaccessible to love, he caused the death of the kindly nymph Echo, who loved him, but in vain. His vanity brought down on him the indignation of heaven (Nemesis), and he was doomed to fall in love with his own image, which he happened to see reflected in a well. According to some, N. pursued, and gradually perished with love for the shadow, while his corpse was changed into a flower that ever after bore his name. Other mythographers make N. melt away into a well in which he loved to view his image. Ovid, Pausanias, &c., narrate this fable, which, considered in any aspect, is of late birth. See Ovid, Met. iii., 341, et seq.; Pausan. ix. 31-6, sec. 6.

Narcissus, a genus of European and N. and W. Asian plants belonging to the natural order *Amoryllidaceæ*. The leaves are linear, flowers with a membranous spathe, solitary or umbellate, large, white or yellow, drooping or inclined, perianth tubular below, segments spreading, mouth surmounted by a circular crown. The number of species was at one time tabulated at 110, but Mr. Baker, our best authority, reduces them to twenty-two. As favourite spring bulbs some have long held a prominent place. Gerard, for instance, in 1596, had ten kinds in his London garden, including the Poet's N. (*N. poeticus*), the Jonquil (q. v.) (*N. Jonquilla*), the Polyanthus N. (*N. Tacetta*), and the Daffodil (q. v.), all of which are in common cultivation at the present day. The common daffodil (*N. Pseudo-Narcissus*) is the only British representative; it is wild in England, and is reported as naturalised in Scotland and Ireland. The *N. biflorus* is also established in some parts of the country as an escape from, or remnant of, cultivation.

Narcotics (Gr. *narkē*, 'stupor') are medicines which subdue irritation, arrest inordinate secretion, allay pain, and cause stupor or sleep. The principal N. are belladonna, chloral,

Narcissus poeticus.

chloroform, cannabis indica, hyoscyamus, lupulus, morphia, nitrite of amyl, opium, and stramonium. The action of N. being modified by age, idiosyncrasy, and prolonged use, they should be employed with great caution, and only under competent advice, more particularly in the case of young children. Any one administering chloroform, laudanum, or other stupefying drug, to help him in the commission of a crime, is guilty of felony, and liable to penal servitude for life, under the statute 24 and 25 Vict. c. 100.

Narcotine ($C_{22}H_{23}NO_7$), an Alkaloid (q. v.) contained in opium to the extent of 6 or 8 per cent. It crystallises in small colourless transparent prisms nearly insoluble in water. Its basic powers are feeble.

Nardo, a town of S. Italy, province of Lecce, 22 miles S.S.W. of the town of that name, and 4 from the Gulf of Taranto. It is a bishop's see, and has a cathedral and old feudal castle. N. is the ancient *Neretum* of the Sallentini. From the 10th to the 15th c. it had a university of note. Pop. (1874) 10,220.

Nardoo, in Botany, the name given by the aborigines of Australia to an acotyledonous plant peculiar to that continent, and belonging to the natural order *Marsileaceæ*. Two or three species are known, the chief being *Marsilea macropus* (Hooker). It bears a considerable resemblance to clover, and grows to a height of from 9 to 12 inches, favouring localities liable to be flooded. The spore-cases are gathered by the blacks when the water has retired, and are pounded by them into a coarse flour or meal, of which they make cakes and a kind of porridge. The food thus obtained, though insipid, is nutritious, and has on several occasions preserved explorers in the desert wastes of Australia from starvation.

Nardus, a genus of *Gramineæ*, consisting of a single species (*N. stricta*) common on heaths, &c., in Britain, and ascending to 3300 feet in the Highlands. Botanically an interesting grass, it is practically of little use. Even sheep reject it on account of its hard divaricate foliage, hence its name of 'wire bent.' It is more commonly called 'mat-grass' from growing in dense mat-like tufts.

Narev, a river in Poland, rises in the Lithuanian swamps of the Russian government of Grodno, flows past the small towns of N., Tikoczin (where it becomes navigable), Ostrolenka, and Pultusk, and after a W. and S.W. course of 295 miles, falls into the Bug at Sierock.

Narghileh (Turk., Pers. *kaloun*; Hind. *hookah*; Chin. *chou-yin*), a species of pipe much used in the East, consisting of a long serpentine tube connected with a vase, which is half filled with perfumed water, through which the smoke passes before it reaches the mouth.

Narra ('a snake'), the name of two of the more important offshoots of the Indus river in Scinde, so named from their tortuous course. The East N. leaves the Indus at Kori, and has a total length of nearly 400 miles. It was formerly only filled in the rainy season; but a permanent artificial connection with the Indus has now been formed for irrigation, and several subordinate channels have been cut. It runs through the Thûr or Sandy Desert towards the Runn of Kutch. The West N. leaves the Indus near Larkhana, and ultimately rejoins it after a course of about 80 miles. During the floods it is much used for navigation, and it also feeds an important canal.

Nar'ses, a great Byzantine general, was born about A.D. 472. A eunuch slave, he appears for the first time in history as the *cubicularius*, or 'groom of the bedchamber,' of the Emperor Justinian at the time of the insurrection of Nika (532), when his services promoted him to the post of keeper of the emperor's privy purse. In 538 he was sent nominally to help, but really to act as a spy and drag upon, Belisarius, whom he joined at the successful siege of Ariminum (Rimini), then held by the Goths. The quarrels of the two generals led to the capture of Milan by the Franks and Burgundians. N. was then recalled to an influential court life lasting 12 years. In 552 he was selected to lead an army of 100,000 for the recovery of Italy from the Goths, who under Totila had occupied almost every place but the port of Ancona. N. marched by the mouth of the Po, Ravenna, and Rimini to Rome, completely defeated Totila at Tagina (Lentaglio), occupied Rome, defeated Teias, Totila's

successor, near Vesuvius in Campania, and returning from the siege of Lucca southwards, destroyed at Casilinum on the Volturno a great horde of Franks and Germans, who had ravaged as far as Calabria under the leadership of Lenthariis or Lothar and Buccellin. In these battles N. had the help of some Lombard tribes. He now became Exarch of Italy, and for 15 years administered at Ravenna the famous *Pragmatic* of Justinian. By means of provincial governors (*comites*) he kept Italy quiet, but heavily drained it by taxation. On the death of Justinian in 565, Justin II. and his wife Sophia took advantage of the complaints against N.'s extortions to replace him by Longinus. N.'s withdrawal was the signal for the Lombards again to appear (it is said in the *De Gestis Longobardorum* at N.'s suggestion), and Pope John III. persuaded the veteran to return to Rome, where, however, he suddenly died in 568. N. was a man of consummate ability, who triumphed over almost every natural disadvantage; but he lacked the chivalrous greatness and pure patriotism of Belisarius (q. v.). See Gibbon's *Decline and Fall of the Roman Empire*.

Nar'thex, a genus of the order Umbelliferae (q. v.), yielding a gummy resin and emitting a fetid odour. The species *N. Asafetida* is found in Persia and Afghanistan, and furnishes the true Asafetida (q. v.). Its leaves somewhat resemble those of the pawny.

Nar'va, or **Nar'ova**, a town of Russia, government of Petersburg, on a river of the same name, about 9 miles from its embouchure in the Gulf of Finland. The town proper is occupied mostly by Germans; the suburb and fortress exclusively by Russians. N. has a harbour, an arsenal, and an exchange. It carries on an active trade in timber, grain, flax, hemp, &c. In 1872 there entered and cleared 44 British vessels of 14,740 tons. Pop. 5921. N. is memorable as the scene of a battle between 8400 Swedes under Charles XII., and 32,000 Russians under the Duke of Croy, fought 30th November 1700, in which the former were victorious.

Narvaez, Don Ramon Maria, Duke of Valencia, was born at Loja in Andalusia, 5th August 1800, and in the revolution of 1820 defended, as an officer, the constitutional régime. In 1822 he distinguished himself in the guerilla warfare of Catalonia, but retired for nine years from active service. As captain in the Princess's regiment he contributed by his personal daring to the victory of Menchigoria, and (1836) under Espartero, after a series of forced marches, he drove the Carlist leader Gomez from his position near Arcos. In 1838 he operated successfully against the brigands of La Mancha, and in 1840 was appointed Captain-General of Old Castile and commandant of a reserve force numbering 40,000 men. The same year he headed the insurrection of Seville, and had to take refuge in France, where (1843) he married Mdle. de Tascher. Through his friendship with Queen Christina, then in France, and a system of intrigue, he succeeded in running the government of Espartero, returned to Spain, and was made Duke of Valencia (1844), with the office of president of council, his ministry lasting for two years. In 1847, 1856, 1864, and 1865 he was called back to office, which he held at his death, May 28, 1868. N. was a courageous soldier, but a haughty, immovable, and illiberal man in administration.

Nar'whal, or **Sea Unicorn** (*Monodon monoceros*), a species of *Cetacean* mammalia, belonging to the dolphin family (*Delphinidae*). Some of the teeth of the upper jaw are very large. The lower jaw is toothless in both sexes; and in the female the upper jaw is also toothless, for the two incisors found in the young never cut the gum. The upper jaw in the male has two molar teeth, and also two teeth erroneously called *incisors*, since they spring from the *Mx. villa* (q. v.), incisor teeth, being those implanted in the *premaxilla*. The right tooth in the male usually remains in a rudimentary condition, while the left is enormously developed, and forms an ivory pole, which may measure from 8 to 10 feet in length.

Narwhal.

This is certainly the largest

tooth in the animal kingdom. It is straight but spirally-twisted, grows during the lifetime of the animal, and springs, like the tusks of the elephant, from a permanent pulp. Occasionally both teeth in the male *N.* may be so developed, while the female *N.* has sometimes a tusk. The *N.* like all Cetaceans, wants the hinder limbs. Its head is round and convex in front, its colour black above, the sides greyish-white and the under parts white. The body is spotted with dark patches and markings. There is no dorsal fin, and the 'flippers' or fore-limbs are small. The average length is 12 or 13 feet. The food of the *N.* consists of oceanic molluscs, cuttle-fishes, and the like. It inhabits the Arctic seas, is generally found in flocks, and is highly valued by the Greenlanders, who obtain oil from its blubber, eat its flesh, and manufacture its skin into various useful articles.

Nasalis or **Pres'bytes**, a genus of *Catarrhine* or Old World Monkeys represented by the *N.* or *P. larvatus*—popularly named the Proboscis Monkey, from the extraordinary size of its nose. This animal occurs in Borneo and other islands of the E. Archipelago. It is also known as the *Kahau*, from its peculiar cry. The nostrils are placed at the tip of the proboscis. The colour of the fur is a light red, and the average height is about 3 feet.

Naseby, a village of Northamptonshire, 7 miles S.W. of Market-Harborough, and the scene of the third great defeat of the Royalists under Charles I. and Prince Rupert by the Parliamentarians under Cromwell, Fairfax, and Ileton, June 14, 1645. The right wing, commanded by Ileton, was routed by a furious charge of Rupert's horse, but on the left the 'Ironsides' won the day. Artillery, baggage, and 5000 prisoners fell into the conquerors' hands, and the war was ended at a blow. A pyramidal monument marks the field of battle.

Nash, John, an English architect, was born in London in 1752. After serving his time to Sir Robert Taylor, the architect, he began business as a surveyor and builder, and was soon able to retire to a small property in Carmarthen. In 1792, however, he returned to London, and was speedily recognised as a prominent architect. In 1815 he was made Surveyor to the Crown Estates, and is chiefly known as the planner and promoter of the various improvements which resulted in the formation of Regent Street and Regent's Park. Of his more purely architectural designs, Buckingham Palace, Haymarket Theatre, and the Pavilion at Brighton, are the most important. He retired from practice of his profession in 1834, and died at East Cowes Castle, May 13, 1835.

Nash, or Nashe, Thomas, born at Lowestoft in Suffolk about 1564, entered St. John's College, Cambridge, and graduated B.A. (1584), but shortly after was expelled the university for his *Terminus a non Terminus*, a satire on the authorities. After rambling awhile on the Continent, *N.* settled at London (1589), and plunging into the Martin Marprelate controversy, produced *A Counterjaffe to Martin Junior*, *Puffe with an Hatchett*, and other caustic pamphlets. He assisted Marlowe in *The Tragedy of Dido* (1590), and his own comedy, *Summer's Last Will and Testament*, was played before Elizabeth (1592). He failed, however, as a dramatist, and in *Pierce Penniless his Supplication to the Diuell* (1592), and *Christ's Teares over Jerusalem* (1593), describes himself as 'sitting up late and rising early, contending with scarcitie, and cursing the daie of his birth.' A fierce attack on Dr. Gabriel Harvey, *Haue with you to Suffron Waldron* (1596), was suppressed by the archbishop, and a satirical play, *The Isle of Dogs* (1597), lodged *N.* in the Fleet Prison. He died about 1600. 'A sharp wit, and the master of a scoffing satyrically merry pen,' is Isaac Walton's estimate of this most brilliant of the Elizabethan pamphleteers.

Nashville, capital of Tennessee, U.S., on the S. bank of the Cumberland River, 200 miles from its confluence with the Ohio. A railway junction, and the seat of the Fisk (1866), Vanderbilt (1875), and N. Universities, it has a splendid state capital built of Tennessee granite, a medical college and hospital, thirty-seven churches, and two daily newspapers. It is the chief commercial city S. of the Ohio, having a vast trade in cottons, tobacco, provisions, drugs, &c. The river is navigable below *N.* for nine months yearly, and is crossed here by two fine bridges. Pop. (1870) 25,865. *N. University*, founded as

the Davidson Academy in 1785, embraces ten 'schools' or educational sections, and is attended by from 400 to 600 students. Its medical school is reputed to be among the very best in America.

Nashua, a city of New Hampshire, U.S., on the W. bank of the Merrimack, 40 miles N.W. of Boston by rail. It produces cottons, machinery, &c., to the annual value of \$7,393,500, and has eleven churches, twenty-eight schools, and two daily and two weekly newspapers. Pop. (1871) 10,543.

Nasmyth, Alexander, the founder of the Scottish school of landscape painting, was born at Edinburgh in 1757, studied art in London under Allan Ramsay, spent several years in Italy, and on his return to Scotland commenced practising as a portrait painter. To the friendship he formed with Burns we owe the only authentic likeness that exists of the national poet. The bent of *N.*'s genius, however, was to the delineation of scenes from nature; to this branch of the art he ultimately devoted himself, and his works were much in request by the Scottish nobility and gentry. *N.* died at Edinburgh 10th April 1843.—**Peter N.**, eldest son of the preceding, was born at Edinburgh in 1786, and early showed a remarkable capacity for art. At the age of twenty he went to London, and soon attained a high reputation. His landscapes are thoroughly English, but nevertheless betray the influence of his favourite masters, Ruysdael and Hobbema. *N.* died at South Lambeth, near London, 17th August 1831. Another son, **James N.**, born at Edinburgh, August 19, 1808, and educated at the High School of his native city, studied four years at the School of Arts, and entered the University. He came to London (1828), and in 1832 opened a small engineering establishment at Manchester. The year following he removed to Patricroft, 4 miles from Manchester, where he realised a considerable fortune by his Bridgewater Foundry, and retired from business (1856). *N.* is the inventor of the Steam Hammer (q. v.), a steam pile-driver, and of various improvements in telescopes and ordnance.

Nassau, capital of the Bahamas, on the N. side of the island of New Providence, has a good strongly-fortified harbour, exports cotton, pimento, salt, &c., and attracts visitors by its excellent climate. It is the centre of the trade of the Bahamas, the total value of whose imports in 1871 amounted to £183,993, and exports £130,292. Pop. 9000.

Nassau, till 1806 a *grafschaft*, and till 1866 a duchy of Germany, was bounded N. by Westphalia, E. and S. by Hessen, and W. by Rhenish Prussia. It had an area of 1795 sq. miles, and a pop. (1801) of 450,507, and is now included in the Prussian province of Hessen-N. (q. v.). The founder of the house of *N.* was Otto of Laurenburg, a brother of Konrad I. (10th c.), but the title of *N.* was not assumed by his descendants till 1160. Heinrich II. ('the rich'), dying in 1255, divided his possessions between his two sons, to Walram IV. bequeathing Idstein, Wiesbaden, and Weilburg; to Otto, Dillenburg, Beilstein, and Sieben. The latter, by intermarriage, became the ancestor of the House of Orange (q. v.); the former transmitted to his descendants the *grafschaft* of N. Friedrich August of N.-Usingen, the head of the Walram line, joined the *Rheinbund* (1806), and was rewarded with the title of duke and an accession of territory, which passed at his death (March 24, 1816) to the collateral branch of N.-Weilburg. *N.* entered the *Zollverein* (1835), was the scene of an insurrection (1848), and having sided with Austria in the Austro-Prussian war, was annexed to Prussia, 8th October 1866, Duke Adolf (born July 24, 1817) receiving a yearly pension. See Schliephake, *Geschichte von N.* (3 vols. Wiesb. 1866 70).

Nassick, the chief town of the district of the same name, Bombay, British India, 106 miles by rail N.E. of Bombay. Pop. (1872) 22,436. For sanctity, it is hardly less revered by the Hindus than Benares; and it also contains many ruins of the Buddhist faith. According to Hindu legend, it is the spot where Lakshmana cut off the nose of the demon Shurpanakha.—The district of *N.*, which contains the sources of the Godavery, has an area of 8140 sq. miles, and a pop. (1872) of 734,386. Cotton is cultivated.

Nasturtium. See CRESS and TROPÆOLUM.

Nasua (*N. rufa*), a species of Carnivorous quadruped, allied to the Raccoon (q. v.), and inhabiting S. America. It is some-

times known as the Red Coaiti, has a reddish fur, black ears and legs, and a long and pointed muzzle. It feeds on birds, eggs, and the smaller quadrupeds. An allied species is the *N. narica* or Quasie, often known as the Brown Coaiti, also a native of S. America.

Natal, a British colony in S.E. Africa, included between 27° 15'—31° S. lat., and 28° 50'—31° 20' E. long. It is bounded on the S.E. by the Indian Ocean, on the N.E. by the Tugela and Buffalo Rivers, on the N.W. and W. by the Drakenberg Mountains, and on the S.W. and S. by the Umtamfuna River. The lozenge-shaped area thus defined includes about 18,750 sq. miles. N. owes its name to the fact of its having been discovered by the Portuguese under Vasco da Gama on Christmas Day, 1497. The discovery remained unfruitful for centuries, for except that the Dutch made a brief and unsuccessful attempt to found a settlement at Port N. in 1760, the country remained unvisited by Europeans till 1823. In the latter year two English naval officers, named Farewell and Flynn, started a trading post near the present site of the town of Durban, but the country being nearly depopulated by the murderous forays of the Zulu chief Chaka (see ZULUS), little trade could be carried on. In 1835 an agreement was arrived at between the Zulu chief Dingaan and the British, by which the latter were to be left unmolested. In 1837 an overland immigration of Dutch Boers from Cape Colony commenced, and led to a fierce war between them and the Zulus, who were ultimately overthrown. The Dutch then declared the territory they had seized to be an independent state, with the name of 'Republic of Natalia.' This was opposed by the Governor of Cape Colony, and after fighting in 1842-43, the Boers were reduced to submission, and N. formally declared to be British territory. In 1847 it was proclaimed a part of Cape Colony, and in 1856 it received a royal charter constituting it an independent colony.

N. descends in a succession of steps or plateaux from the Drakenberg range, which on this side rises precipitously to a maximum height of 10,000 feet. The country is thus divided into zones differing in temperature and general characteristics. Thus the central portion, which consists of a grassy plateau from 5000 to 6000 feet above the sea-level, is excellently adapted for sheep and cattle, while the coast region produces sugar, coffee, and other semi-tropical crops. The descent of the land from the watershed being rapid, not one of the fifty rivers is of any use for navigation, and for the most part they flow in rocky kloofs, or gorges, and are interrupted by continual rapids and falls. No lakes exist, and the only tolerable harbour is that of Port N., but though landlocked, it has a rather shallow bar entrance. On the highlands of the interior, the heat, which is excessive on the coast, is much mitigated, and at Pietermaritzburg, on the first plateau ascending from the sea, the annual mean temperature is about 67°. Rain is abundant in summer, falling principally during thunderstorms, which are very frequent. The mean annual rainfall at Pietermaritzburg is 30.11 inches. N. contains large quantities of coal of fine quality, but pending the establishment of railway communication between the coalfields and the coast, the deposits remain undeveloped. Iron is also plentiful, and copper and gold are known to exist in small quantities. Near the mouth of Umzimkulu river, close to the S. frontier, there is a remarkable formation of white marble, covering an area of 30 square miles, and believed to be 1200 feet thick.

The wild animals found in N. are very numerous. The lion, buffalo, and elephant indeed are now scarce, and the giraffe and rhinoceros have wholly disappeared from the country, but the hippopotamus is still common, and hyenas and leopards abound. Of the other larger animals still frequently to be met with, the chief are ten species of antelope, the chacma or S. African baboon, the ant-eater, iguana, and crocodile. The avifauna is varied and interesting, and the snakes include a number of poisonous species, as well as a harmless python, which attains a length of from 16 to 25 feet. Insect life is abundant, but the dreaded tsetse fly is never seen in N. The flora of N. includes a number of valuable timber trees, and amongst its most characteristic forms are the strelitzia, tree-aloe, and giant euphorbia. Ferns are numerous, but the heaths so abundant in Cape Colony are not found in N.

The principal exports of N. are wool, hides and skins, sugar, coffee, ivory, and ostrich feathers, and among those of minor

importance at present are cotton and arrowroot. The cultivation of sugar was commenced in 1851, but was much hampered by the want of proper labour, until in 1865 the introduction of coolies from India was commenced. In 1875 there was exported from N. 155,515 cwt. of sugar, of the value of £169,815, besides rum to the value of £4259. The quantity of wool exported in the same year amounted to 8,108,397 lbs., valued at £389,257. The total trade of the colony in 1876 amounted to £1,680,286, the imports amounting to £1,022,896, and the exports to £657,390.

N. is governed by a Lieutenant-Governor appointed by the Crown, an Executive Council composed of four official and two non-official members, and a Legislative Council, consisting (in addition to the members of the Executive Council) of eight members nominated by the Government, and fifteen elected by the constituencies. The colony is divided into nine counties, and contains thirteen towns, of which the principal are Pietermaritzburg (q. v.), the capital, and Durban, the seaport. A railway to connect these two places is (1877) in course of construction. Durban is the larger of the two, having in 1877 a population of 10,488, which causes it to rank after Cape Town and Port Elizabeth as the third largest town in S. Africa.

The population of N. is unusually dense for S. Africa, and was estimated to amount at the end of 1876 to about 310,000, of whom the natives numbered 281,000, those of European descent 19,000, and the Hindu and Chinese coolies 10,600. The natives consist of various Zulu tribes, who have crossed the border from their own land on account of the greater security to life and property enjoyed under British rule as compared with that of their own king. Their numbers are yearly increasing, and the immense preponderance of this savage population is the cause of considerable disquietude to the European minority. See *An Address on South Africa and Her Colonies*, by Lieut.-General Bisset (Lond. 1876); *Handbook to South Africa* (Lond. 1876); *Natal*, by H. Brooks, edited by D. Mann (Lond. 1876); *South Africa Past and Present*, by John Noble (Lond. 1877).

Natal, capital of the province of Rio Grande do Norte, Brazil, on the Potengi, has a good harbour, the entrance of which, however, is impeded by a sand-bar. It exports Brazil-wood, cotton, and rice. Pop. 10,000.

Natatores, an order of Birds represented by the various kinds of 'swimmers.' The body is boat-shaped, and the legs being, as a rule, placed far back, are well adapted for swimming, but give an awkward appearance to the movements of the birds on land. The neck is generally long. The toes are webbed; the membrane sometimes uniting all four digits (as in cormorants), or the hinder toe may be free (as in gulls); while in petrels, &c., the hinder toe is only rudimentary. In others again the web is broken up into broad fringes. The body is covered with 'down,' and the 'oil gland' is large, its secretion being used to protect the feathers from the action of the water. The N. are usually *polygamous*, one male mating with several females. The young are able to run about and swim on quitting the egg.

Natchez, a town of Mississippi, U.S., on the E. bank of the Mississippi River, 280 miles N. of New Orleans. It has a large river trade in cotton and some timber sawing, and cotton seed oil making. Pop. (1870) 9057. N. is named after a noted Indian tribe of whom some 300 are still living.

Natica, a genus of *Mollusca* belonging to the *Gastropoda* (q. v.). It is typical of the family *Naticidae*, in which the shell is globular and consists of a few whorls. The 'spire' of the shell is small, and the outer lip acute. The genus is distinguished by a very large foot, and the mantle-lobes cover a great part of the shell.

National Convention was the representative assembly of France, which met for the first time, September 21, 1792. It was composed of three parties, all of whom held the theory of Republican government. The Girondists or 'Right' were favourable to constitutional law, the Mountain or 'Left' adhered to the most uncompromising principles of the Revolution, the Marsh (*Marais*) voted and spoke sometimes with the one and sometimes with the other, earning thereby the detestation and contempt of both. After it was decreed that 'royalty was abolished

in France, it became apparent that between the Right and Left a deadly struggle must ensue, and the first six months were occupied in determining the issues of the contest. By the 2d of June 1793 the Girondists were extinguished as a party. During that period Louis XVI. was tried and executed, and war was declared against a complete European coalition. Until the 26th July 1794 the Mountain led, and under it the Committee of General Safety, which afterwards destroyed both itself and the Commune, commanded the N. C. At one time the N. C. had fourteen armies, and 1,200,000 soldiers under arms. It abolished the Catholic religion and established the worship of reason. During its existence Danton and Robespierre both flourished and fell. From the 26th July until the 26th of October 1795, when the N. C. decreed its own dissolution, the struggle was between the adherents of the moderate Republic against both revolutionary and royalist parties. The three years during which the N. C. lasted are the most memorable, not only in the history of France, but in the history of the representative institutions of the world. See Carlyle's *History of the French Revolution*, and the works of Mignet and Thiers on the same period.

National Covenant. See COVENANT.

National Debt. See DEBT, NATIONAL.

National Guard, The, till 1853 the bourgeois militia of France, was founded (1790) in accordance with a proposal of Mirabeau, and was organised by Lafayette. Suppressed in 1827, but revived in 1830, and reorganised in 1831 and 1852, it was finally abolished by the Act of 1872, in consequence of the share 100,000 of its members had taken in the Communist insurrection. By a law of 1868 the N. G. was defined as 'an auxiliary to the active army in the defence of the frontier of the empire, and in the maintenance of order in the interior, liable to be called up for active service only by a special law,' and every Frenchman who had reached the age of twenty-one was obliged to serve either in it or in the active army.

Nations, Law of. See INTERNATIONAL LAW.

Nat'ron, or Tro'na, is the native impure sesquicarbonate of sodium $\text{C}_2\text{O}_8\text{Na}_4 + 3\text{H}_2\text{O}$. Originally it was known as an encrusted deposit obtained on the shores of the soda lakes in the Nile delta of Egypt. Under the name of *Urao* it is found extensively in Venezuela, and now great supplies are obtained in Virginia, besides which it is found to a large extent in many other localities.

Natt'erjack (*Bufo calamita*), a species of Toad (q. v.) common in many parts of England. The hind legs are shorter than those of the common toad, and its eyes more prominent. The legs are banded with black, and a yellow line passes along the middle of the back. The N. appears to be less dependent on moisture than the common toad, and is found in dry places. Its length is about 3 inches.

Nattore', a town in the district of Rajshahye, Bengal, British India, on the N. bank of the Nurud, an offshoot of the Ganges, 196 miles N. of Calcutta. Pop. (1872) 9674. Owing to its unhealthyness, the administrative headquarters were removed in 1822, but it is still the residence of the Rajah of N., the representative of the wealthiest Hindu family in Bengal of the last century.

Nat'ural, in Music (♩), before a note, contradicts a previously governing sharp or flat placed at the beginning of a staff or elsewhere, restoring the note to a place in the natural scale of C (a white key of the pianoforte).

Natural Child. See BASTARD.

Natural History. Probably no term in science has had attached to it so many and diverse meanings as this. Some use it to signify Zoology (q. v.), the science that deals with the animal creation. Others designate by it biology, or the science which deals with organic life (animal and vegetable); while others again employ it to cover the entire range of subjects and sciences connected with the visible world. There can be little doubt that in its true significance, the term should be employed according to the last of these three meanings. A 'history of nature' should comprehend not merely the history of the animated portion of

this universe, but of all natural objects. In this sense Aristotle and the ancient investigators were 'natural historians,' pure and simple. Their researches extended over a wide field, and included all the subjects which might be regarded as affording a knowledge of the universe at large. As time passed, however, the N. H. of the ancients became subdivided into many branches, and the term lost its comprehensive meaning, acquiring its present loose and unsatisfactory application. This is to be regretted. It is the first business of science to be exact. When properly used, the term 'N. H.' should indicate the collection of sciences devoted to the examination of the universe and its constitution. The term 'physical sciences' might be held to be synonymous with 'N. H.' in this sense. Leaving out the more subordinate branches of inquiry, and also the multifarious subdivisions into which each science might be divided, N. H. may be said to consist (I.) of the *Organic sciences*, and (II.) *Inorganic sciences*. The first series comprehends *Biology* alone, and this department, dealing with organic or living things, includes (1) *Botany*, or the science of plants, and (2) *Zoology*, or that of animals. The Inorganic sciences include (1) *Chemistry*, (2) *Natural Philosophy* or *Physics*, (3) *Geology*, and (4) *Mineralogy*—this last being rightly enough regarded by many as a subdivision of geology, and also as closely allied to chemistry.

Naturalisation, in Law, is the act of investing an alien with the rights of a born countryman or citizen. See ALIEN, DENIZEN.

Naturalisation. An animal is said to be naturalised when it has become accustomed to a new country or area, and adapted to new environments and surroundings, as if these were 'natural.' N. thus differs from *Acclimatisation* (q. v.) in the fact that naturalised animals return to a state of nature in their new area. Acclimatised animals, on the other hand, are such as live and flourish in a new country, especially under the care of man. Acclimatisation, however, in many instances is a preliminary measure to N. The horse has become naturalised in America, for example, in the most thorough manner, but the animal was at first acclimatised in that continent through human agency. The horse can support itself, and lives indeed in a wild state in America. A case of very complete N. is also presented by the case of the *Dreissena* (q. v.), a foreign mollusc which was introduced into our streams, and which first acclimatised itself, and then became completely naturalised. The same result has followed the chance introduction of some American water-weeds, which have become so thoroughly naturalised in many of our streams as to require repression.

In *Botany*, the word has been so variously and carelessly applied that it has ceased to carry with it any exact signification. It ought to mean that a species originally introduced by man has now become thoroughly established, by seed or otherwise, among the native plants of the country, and exists without human aid in sowing its seeds or in preparing the ground for them. (It is so employed in the articles of this work.) There are in Britain two American plants fully coming up to this definition—*Impatiens fulva* and *Elodea Canadensis*. Few botanists, however, restrict the use of the term to this just and proper meaning, while some even apply it to mere casuals, stragglers from cultivation, with no permanent or certain locality. Mr. H. C. Watson, who has given much attention to the subject, proposes to discard the word 'naturalised,' and he employs in his works the terms Native, Denizen, Colonist, Alien, and Casual, to express a descending series, from the truly wild and prehistorically established species, down to the occasional stragglers of cultivation, or the product of seeds accidentally imported with merchandise, ship-ballast, or otherwise.

Natural Obligation is an obligation which is held to arise from a law of nature; for instance, the obligation of a parent to maintain his child is a N. O., though it is a legal one also. It might be held a N. O. for a wealthy brother reasonably to maintain a poor sister, in which case there is no legal obligation. If we see a fellow creature in danger or distress, and we can relieve him without loss or injury to self, the principle which some authorities have termed 'the Law of Nature' requires us to do so; though, perhaps, the witty saying of Sidney Smith may not be wholly without truth, that 'when A sees B in distress he feels immediately prompted to call upon C to relieve him.'

Natural Theology, as a branch of theology in general deals with those facts regarding the nature of God and our relation to Him which are deduced from the works of God and the nature of man. With regard to N. T. two leading views are held diametrically opposed to each other. The one that the works of Nature, meaning thereby the external, material universe, afford no trustworthy revelation of the being and perfections of God, the usual ontological and teleological arguments derived from the existence of the universe and the evidences of design which it contains being held to be unsatisfactory; the other, that the revelation afforded by them is so clear and comprehensive as to preclude the necessity for any supernatural revelation. See the works of Paley and Chalmers, and the *Bridgewater Treatises*.

Nature Printing is the name applied to a technical process of causing flat objects, as ferns, mosses, feathers, lace, &c., to engrave themselves by pressure on metal plates, from which impressions may be printed. Kyhl, a Danish goldsmith, seems to have been the first to obtain, about 1833, copies of natural objects by pressure. From 1849 to 1852, several experiments in the art of N. P. were made by Dr. Branson of Sheffield, Mr. Aitken, and Mr. Sturge of Birmingham, and others. Subsequently Mr. H. Bradbury introduced into England a process that had attained considerable perfection in the imperial printing office at Vienna. This process, as improved, consists in embedding, by pressure with steel rollers, any flat object in a plate of pure soft lead. An electrotype facsimile is then taken, from which the impressions are printed off in different colours on a peculiar soft paper. The object depicted on paper has an embossed appearance, and its characteristic markings, even to the most minute, are accurately and faithfully brought out. Several botanical works have been illustrated by means of this art, the first in England being *The Ferns of Great Britain and Ireland*, by Lindley and Moore.

Naudé, Gabriel, born in Paris, February 1, 1600, studied philosophy and medicine at Paris and Padua (1626), and became librarian at Rome to the Cardinals Bagni (1629) and Barberini (1641), and at Paris to Mazarin (1642). Having formed the design of founding a great national library, he made a bibliographical tour in Flanders, Italy, Germany, and England, and thus collected some 40,000 volumes for the Bibliothèque Mazarine, which was opened in 1648. On the dispersion of this library by the Fronde Parliament (Dec. 29, 1651), N. purchased 3500 of its medical works, and withdrew to Stockholm, where Christina appointed him her librarian. Recalled by Mazarin, he died on the homeward journey at Abbeville, July 29, 1653. N. was a voluminous writer, but his works (mostly in Latin) are extremely rare. The principal are *Apologie pour les grands Personages faussement soupçonnés de Magie* (1625), *Advis pour dresser une Bibliothèque* (1627), and *Bibliographia Politica* (1633). See A. Franklin's *Histoire de la Bibliothèque Mazarine* (Par. 1860).

Naumachia (Gr. *naus*, 'a ship,' and *machē*, 'a fight'), literally a sea-fight, but generally the name given to a representation of such by the Romans, as well as to the scene of its occurrence. Such naval battles (*navalia prœlia*) were frequently celebrated in the circus (the arena being filled with water). With a view to the celebration of the N., ponds (*stagna*) were dug near the Tiber by Julius Cæsar, Augustus, and Domitian, a grove (*nemus*) being planted around them. Claudius turned the Lacus Fucinus into a magnificent field for such spectacles. Nero converted an amphitheatre to the same purpose. The combatants in these fights were termed *Naumacharii*. They were generally captives or criminals compelled to fight in gladiatorial combats. The ships engaged in such sea-fights were designated by the names of different maritime nations, e.g., Tyrians and Egyptians, Rhodians and Sicilians, Persians and Athenians. The same lavish expenditure which characterised the gladiatorial exhibitions distinguished the N. In the N. exhibited by Titus 3000 men were engaged; while in the '*spectacle*' given by Domitian, two real fleets to a nearness (*parve jacte classis*) entered the lists. In the combat on the Lacus Fucinus 19,000 combatants engaged—fifty ships a-side (cf. Dion Cass. ix. 33).

Naumann, Johann Friedrich, a famous German ornithologist, born 14th February 1780 at Ziebigk, near Köthen, and died there, 15th August 1857. His chief works are *Na-*

turgeschichte der Vögel Deutschlands (2d ed. 12 vols. 1822-44; *Nachträge*, 1846-60); *Taxidermie* (2d ed. 1848); *Haushalt der Nördlichen Seenvögel Europas* (1824). In his honour the journal of the German Ornithological Society is named *Naumannia*.—**Karl Friedrich N.**, a well-known German mineralogist, born at Diesden, 30th May 1797, was Professor at Freiberg from 1826, afterwards at Leipzig from 1842 to 1870, and died 26th November 1873. He wrote *Lehrbuch der Krystallographie* (2 vols. 1830, 2d ed. 1858); *Elemente der Mineralogie* (8th ed. 1871); *Lehrbuch der Geognosie* (2d ed. 3 vols. 1857-67).

Naumburg (a corruption of *Neuenburg*, 'New Town'), a town of Prussia, province of Saxony, on the river Saale, in a hilly wine-growing district, 17 miles S.S.W. of Merseburg by rail. It has a cathedral of the 13th c., in the transition Gothic of the period, and richly adorned with curious sculptures. The industrial products are sparkling wines, chemicals, vinegar, tobacco, spirits, linens, and woollens. The district yields over 100,000 gallons of wine yearly. Pop. (1875) 16,327.

Nauplia, or **Nauplion** (Ital. *Napoli di Romania*), a town of Greece, in the nomarchy of Argolis and Corinth, picturesquely situated on the Gulf of N., 28 miles S.S.W. of Corinth. It is the see of an archbishop, and from 1829 to 1834 was the chief town of Greece. N. has an excellent harbour, capable of holding 600 vessels, and is protected by three forts, Palamidi, Albanitiki, and Itchkali, on a rock 709 feet high. In the suburb Pronia a huge lion cut out of the rock commemorates the Bavarians that fell in Greece. To the N. are the Cyclopean ruins of primeval *Tyrus*, enormous stones of irregular polygonal form rudely piled one above another. Pop. (1870) 3958.

Nausea (from Gr. *naus*, 'a ship') literally means sea-sickness, or a similar sickness of the stomach, accompanied with a propensity to vomit. N. is usually accompanied by general languor, muscular relaxation, an increased flow of saliva, a small irregular pulse, and a cool, moist skin. N. may be a direct symptom of stomach disease, or of the presence of irritating substances; or it may be an indirect symptom of disease in remote organs, as the brain or the kidneys, and it is frequently an early symptom of zymotic diseases. The N. of pregnancy depends on the reflex action of the gravid uterus on the stomach. N. after taking food is a troublesome affection, and to soothe this irritability there are special therapeutic remedies—in addition to careful regulation of the quantity and quality of food—such as creosote and hydrocyanic acid.

Nautæ, Caupo'nes, Stabularii, the opening words of the well-known edict of the Roman prætor, by which shipmasters, innkeepers, and keepers of stables were made answerable for the safety of the goods of the travellers brought with them into the ship, inn, or stable. The same rule has been adopted by the common law of England and of Scotland. The rule has, however, been modified under various statutes. See under CARRIERS, *Carriers, Wharfingers, and Warehousemen*, LAW REGARDING; INNKEEPER, LAW AFFECTING THE.

Nautch Girls, or Nautchias. See BAYADERES.

Nautical Almanac. See ALMANAC.

Nautilus, a name given to two distinct and widely different species of *Cephalopoda* (q. v.) or cuttlefishes. Of these the first is the *Paper N.* (*Argonauta Argo*) belonging to the *Dibranchiate* or two-gilled group, in which the shell is external, but single-chambered, the arms number eight, and are provided with suckers, and an ink-sac is developed. The shell of the paper N., however, is not a true shell, as it is not formed by the mantle of the animal, but by two of the arms specially modified as shell-secreting organs. The typical N. is the 'Pearly N.' (*Nautilus Pompilius*), the only living representative of the Tetrabranchiate or four-gilled cuttlefishes. This animal has a true external, many-chambered shell, numerous arms, and no ink-sac or suckers. It is one of the rarest of molluscs. Only some four or five specimens have been obtained. It occurs in the Southern seas, and lives at great depths. The shell is well known, and is frequently found in drawing-rooms; the brown and white markings having been obliterated by its surface having been polished so as to give the shell the pearly lustre from which the N. gets its name. The shell forms a flat spiral. Its chambers are completely shut off from each other by *septa* or

partitions. In the middle of each septum a small aperture exists for the transmission of a muscular tube, the *sipuncle*, which terminates anteriorly in the *pericardium* or heart-sac. The function of the sipuncle is supposed to be that of keeping up a low kind of vitality in the disused chambers of the shell; while others think it acts as a hydrostatic apparatus, enabling the animal to rise or sink in the water by the diffusion of water or gas through the chambers of the shell. The chambered condition of the shell is produced by the successive growths of the animal. In early life the shell consists of but one chamber, but owing to its increase of size, the animal soon leaves the first-formed chamber, constructs a second and larger one, and partitions off the first by a septum. The third chamber is similarly formed and similarly partitioned off from the second when the latter has grown too small to contain the animal; and in this way the convoluted shell is produced. The development of the N. is unknown. It has no 'branchial hearts' such as occur in the cuttlefish; its tentacles are very numerous, and want suckers or *acetabula*. Fossil N. first occur in the Silurian rocks, and are found through the whole fossiliferous series up to the present day. The genus probably attained the maximum of its development in Palaeozoic strata.

Nauvoo, a town of Illinois, U.S., on the E. bank of the Mississippi, was founded in 1840 by the Mormons, and after their expulsion became the home of a community of French socialists under M. Cabet. In 1846 it had 15,000 inhabitants, but it has since dwindled into a mere village. Pop. (1870) 1578. N., however, produces yearly about 100,000 gallons of wine.

Naval Cadets enter the Royal Navy as such between twelve and fourteen years of age after passing an examination, and serve two years on board the *Britannia*, a training ship at Dartmouth. If they do not obtain first-class certificates at the end of that time, they have to serve for a further period on board a sea-going training ship before taking rank as midshipmen. See MIDSHIPMAN.

Naval Crown, in Heraldry, is a rim of gold adorned alternately with ships' bows and square sails. The origin of the device, according to tradition, goes back to the Emperor Claudius, who instituted it after the conquest of Britain.

Naval Reserve, an auxiliary naval force, which sprung into existence about the same time as the volunteer movement. It is to the navy what the militia is to the army. Formerly, although the abolition of impressment had closed the great source on which Government could draw for the maintenance of the navy in time of war, the only reserve was a body of coast volunteers, who could not be sent more than 300 miles away from their coast. The present force was established as regards the men in 1859, under Act 22 and 23 Vic. cap. 40, and as regards the officers in 1861, under Act 24 and 25 Vic. cap. 129. The number was limited to 30,000 men and 400 officers, though this number has never been actually enrolled. In 1876, 18,000 men were provided for, their wages and allowances being estimated at £134,700. The men, who must be under thirty-five years of age and have served at least five out of the previous ten years at sea, join for five years, and have to train (in periods of seven or more days, or altogether if they prefer it) for twenty-eight days in the year on board one of Her Majesty's ships or with the coastguard, during which period they receive the wages of seamen in the Royal Navy, in addition to a bounty of £6 per annum. On an emergency they may be sent on naval service to any part of the world for a period not exceeding five years. On attaining certain ages, fixed according to special circumstances by the Board of Admiralty, they become entitled to pensions of £12 a year, or to a smaller annual sum payable during the longest lives of themselves and wives. If they have been three years in active service the pension is increased by 2d. a day. Chief mates in the merchant service are eligible as sub-lieutenants in the reserve, receiving 7s. a day during the training period; masters as lieutenants, at 10s. a day. Pensions are granted to these officers if wounded, or to their widows if they are killed in action, at same rates as in the Royal Navy.

Naval Stores Act. By this Act certain marks are appropriated to denote Her Majesty's property in stores. Any one oblittering such a mark is guilty of felony. No one is allowed, without authority, to sweep or search for stores, or dredge in the

sea, within one hundred yards of any one of Her Majesty's vessels, or of any dockyard or mooring, under penalty of fine or imprisonment. See BROAD ARROW.

Naval Wills Act. After 1st January 1866, wills of seamen or marines made previous to their entering into service, of wages, prize, bounty, or other allowance payable by the Admiralty, or in its charge, are declared invalid. To make valid a will of money or effects in charge of the Admiralty, it must be executed with the forms prescribed by the Wills Act. If the will be made on board ship, it must be attested by an officer.

Navan (Irish Gael. *n'Eamhain*, lit. 'the neck brooch,' so named from a legend connected with the foundation of an ancient palace there), is a market-town in Ireland, county of Meath, at the confluence of the Boyne and Blackwater, 29 miles N.N.W. of Dublin by rail. It has considerable trade in provisions, and manufactures flour, sacking, leather, and spirits. Pop. (1871) 4104.

Navarino, Bay of, an indentation of the south-western coast of the Morea, in the nomarchy of Messenia, is about 3 miles wide by 2½ deep. The island of Sphagia or Sphacteria lies across its entrance, leaving two narrow inlets, on the upper of which stood the Frankish fortress of Paleocavario (the *Pylus* of Nestor), while on the lower is the strongly-fortified haven of N. or Neokastro, with a pop. (1870) of 1115. In this bay Cleon and Demosthenes defeated the Spartans (425 B.C.), and a Turco-Egyptian fleet was almost totally destroyed by the combined fleets of France, England, and Russia, under Sir Edward Collington, October 20, 1827.

Navarre (Sp. *Navarra*, a Basque word meaning 'the plain among the hills'; the anc. *Vasconia*), a former kingdom and now a province of Spain, is bounded N. by France, S. by Old Castile, E. by Aragon, and W. by Guipuzcoa. Area, 4044 sq. miles; pop. (1870) 318,687. The wild highland region of the Pyrenees in the N., known as Montaña, attains its highest elevation of 4908 feet in Monte Adi, and is intersected by many beautiful valleys, such as Roncal, Aezcoa, Roncesvalles, and Ebro. The lofty Sierra de Andia, the eastern extremity of the Cantabrian Mountains, enters the province in the W., while the centre is occupied by the plain of La Cuenca or Pamplona, and along the deep and rapid Ebro, which forms the southern boundary, stretches the level Ribera, famed for its wines, especially those of Vicalta, Azagia, and Cascante. Most of the rivers, the Aragon, Zidaco, Aiga, Ega, &c., are affluents of the Ebro, and traverse N. in a southerly direction; the Bidasson, however, after watering the valley of Batzan (Arab. 'garden'), in the extreme N.W., flows towards the Bay of Biscay. The slopes of the mountains are clad with extensive forests of pine, oak, chestnut, and beech trees, and afford pasture to vast herds of cattle and flocks of merino sheep. Among the products that are exported are wheat, timber, wine, brandy, olive-oil, wool, iron, salt, and skins. Seven roads and numerous bridle-paths cross the Pyrenees, and a great deal of smuggling is carried on along the frontier. The Navarrese, a mixed Basque and Gothic race, impulsive, superstitious, and hardy, are born soldiers and sons of the chase. The mountaineers, who have preserved their purity of descent by intermarriage, speak Basque, and are jealous of ancient customs; but the inhabitants of the plains have lost many distinguishing traits, and use the language of Castile.

The earliest known inhabitants of this region, called Vascones ('Basques') by the Romans, were subdued by the Goths about 470 A.D. The Goths and Vascones gradually amalgamated, and were early brought under the influence of Christianity. About the beginning of the 8th c. the country was invaded by Arab hordes, and the inhabitants who escaped the sword fled to the mountains. Choosing as their leader or king a knight named Garcia Ximenes, they sallied from the glens of the Pyrenees, and succeeded in ridding their country of the infidel invaders. A dynasty founded by Ximenes ruled the little kingdom till the middle of the 9th c., and on the extinction of the race, the Navarrese elected Inigo Sanchez, Count of Bigorre, whose descendants reigned for nearly five centuries. The marriage of Joanna I. of N. to Philippe the Fair made the country tributary to France (1285), and on the succession of the family of Valois in 1328, it passed to Joanna II., the daughter of Louis X. In 1442 Juan II. of Aragon married Blanche, daughter of Carlos III. of N., and the alliance led subsequently to a period of fierce family

strife. Ferdinand and Isabella failed in an attempt to procure the hand of Catherine of N. for their son, the Prince of Asturias; a pretext, however, was immediately found for invasion, and Ferdinand in 1562 annexed the part of N. forming the modern province. A small territory called Lower N., on the N. side of the Pyrenees, now included in the department Basses-Pyrenees, was seized in 1572 by Henri IV. of Bourbon, the famous Henri of N., on the ground of descent from Queen Catherine, and formally annexed to the crown of France in 1609. In recent times the Navarrese lent their aid to the Pretender during the Carlist Wars, and in consequence have been deprived of their municipal charters, their *fueros*, and other constitutional privileges.

Nave (Fr. *nef*, from Lat. *navis*), the body or middle of a church, often flanked by aisles, and parted from the chancel by a rood-screen. Its roof is commonly the highest in the building, and it contains the pulpit, lectern, fald-stool, and font, besides chairs or fixed benches for the general congregation. Of English cathedrals, Peterborough has the longest N., 234 feet; and York the widest, 106 feet, inclusive of the aisles.

Navew is 'a garden vegetable much cultivated in France and other parts of Europe, although little used in Britain. The part used is the swollen root, as in the turnip, but it is rather like the carrot in shape, and its colour is white.' No doubt it is one of the forms of the Protean *Brassica campestris*, as the different kinds of navet or navette of the French are all reckoned to belong to that species in its full Linnæan acceptance.

Navic'ula, the name given to a genus of *Diatomacea* (q. v.), from the shape of the flinty or siliceous envelope, which bears a close resemblance to the form of a little ship. This genus includes a large number of common species.

Navic'ular Disease, a lesion affecting the flexor tendon of the foot of the horse, at the portion which lies in relation with the *navicular bone*. The most frequent cause of N. D. appears to be a strain of the tendon, resulting from severe work, sudden exertion, or from being unduly worked on hard roads without careful attention to the state of the feet. The horses which suffer most frequently from N. D. are light draught horses. The symptoms consist of a short stepping gait, the affected foot being placed on the ground cautiously, and being quickly raised and replaced by the opposite or sound limb. The muscles of the shoulder undergo waste or atrophy, and the affected limb is usually protruded when the animal is at rest. The treatment to be effectual must be prompt. Rest, removal of the shoe, paring of the hoof in front, and poulticing are measures necessary for successful treatment; while mashes should be given, and aperients are indicated. Cold bathing frequently applied should succeed the poulticing, and if much swelling remain, a blister may be applied round the top of the hoof. Occasionally blistering of the ankle has been followed by relief. The animal, in order to be thoroughly cured, should be allowed to remain at grass for six weeks or two months, so as to ensure the soundness of the limb before a return to the road. Division of the nerve has been practised in this lesion. This latter plan relieves pain, but appears to be of no ultimate benefit.

Nav'ies, the war marines of nations, originated in prehistoric times with the Phœnicians, who fitted out hundreds of armed vessels for the protection of their commerce and colonies from piracy. Triremes were first employed by the Corinthians in their war with Corcyra (664 B.C.), and the naval supremacy of Athens dated from a decree of Themistocles (481) for the immediate building of 200 ships-of-war, and of twenty new ones every year from that time forth. At Salamis (480) the total Greek fleet consisted of 300, the Persian of 1000 vessels. In the time of Alexander the Great (330) the Athenian navy alone numbered 300 triremes, most of them 125 feet long by 20 broad, furnished with sails and oars, and with a beak (*embolos*, Lat. *rostrum*) for ramming down the enemy. The average number of the crew and marines was 200. The Roman navy arose during the Second Samnite War (311), but only obtained importance in 260, when 100 quinqueremes and 20 triremes were built to act against the Carthaginians, 200 of whose ships were defeated off the coast of Sicily by the consul Duilius. The Romans, however, were never a truly maritime people, and by means of the *corvus* or grappling-iron, and by the erection of towers upon the decks, converted a sea-fight as nearly as possible

into a land engagement. The number of marines on board their vessels was 120. At Actium (31 B.C.) Octavian's fleet consisted of 260, Antony's of 280 vessels. For the first nine centuries of the Christian era, naval science rather retrograded than advanced. The Norsemen and Moorish pirates scoured the European waters, but battles by sea ceased to decide the fate of nations. Then arose the medieval N. of Venice, Genoa, and Aragon, but these powers confined their efforts to the narrow limits of the Mediterranean, and regarded ships as a means, not an end, as instruments rather of transport and commerce than of conquest and discovery. Consequently their galleys were little, if at all, superior, to the vessels of the ancients. The discovery of the compass, the application of artillery to naval warfare, and the opening up of new fields of navigation, gave an immense impulse to the creation of N. Sails gradually superseded oars, and hand-to-hand encounters, like those of Sluys (1340) and Harfleur (1416), became a thing of the past. Columbus' squadron was composed of three ships, two of them undecked, manned by 120 men, but in the next thirty years vessels began to be built of 1000 tons, carrying from 80 to 100 guns, and in 1587 we see the Spanish Armada with its 130 huge galleons, 2500 cannon, 8000 seamen, and 20,000 soldiers. On the downfall of Spain as a maritime power, France, England, and the Low Countries struggled for the supremacy of the sea, but continued to build their ships on the old lines, and Nelson's *Victory* differed in no essential points from the *Great Harry*. The navy of Russia arose under Peter the Great (q. v.), that of America in the War of Independence (1775). Modern N. owe their development to the application of steam to war-vessels (1838), and the invention of the screw-propeller, armour plates, improved ordnance, turret-ships, rams, torpedoes, &c. What possible effects the two last-named may have on naval warfare has been already to some degree instanced in the sinking of the *Vanguard* by the ram of the *Iron Duke* (September 1, 1875), and in the destruction of Turkish monitors by Russian torpedoes in the Russo-Turkish War of 1877. See Benedict, *Geschichte der Schifffahrt der Alten*; Jal, *Archéologie Navale* (Par. 1840); Commander King, *The War Ships of Europe* (Portsm. 1877); and *Gün, Ram, and Torpedo* (Portsm. 1877).

The following statistics of the chief naval powers are for the year 1876, except where otherwise specified:—

Austria has 57 vessels, viz., 10 ironclads (of 7650 tons), 37 unarmoured steamers, and 10 sailing vessels, armed with 563 guns, and manned by 408 officers and 5836 men, while the marines comprised 34 officers and 850 privates. On a war-footing the seamen are to number 11,532, and the marines 1500. The term of service is ten years, the two last in the reserve; and the navy is recruited by a general levy from the seafaring population of the empire. Naval expenditure, £1,094,943.

Denmark has 30 steamers, viz., 6 ironclads (of 2355 horsepower), 12 unarmoured vessels, 7 gunboats, and 5 paddle-steamers, armed with 314 guns, and manned by 97 officers and 911 men, who are raised by conscription from the coast population. Expenditure, £265,052.

France has 391 vessels, viz., 52 ironclads (of 30,240 horsepower), 264 unarmoured screw-steamers, 62 paddle-steamers, and 113 sailing vessels armed with 2978 guns, and manned by 1531 officers and crews drawn from the *Inscription Maritime*, which fluctuates between 150,000 and 180,000 men. The marines comprise four regiments of infantry of 16,000 men and a body of artillery of 4500 men. The navy is recruited partly by conscription, partly by voluntary enlistment, and the term of service is the same as in the army. Expenditure, £5,455,499.

Germany has 66 vessels of 83,342 tons, viz., 12 ironclads (of 42,050 tons), 20 unarmoured steamers, 31 gunboats, and 4 sailing vessels, armed with 478 guns, and manned by 255 officers, 5500 seamen, and 1500 marines. Sailors and marines are raised by conscription from the seafaring population, which is estimated at 80,000.

Great Britain on 1st December 1875 had 241 ships in commission; and her ironclad fleet, at the end of 1876, consisted of 47 efficient vessels of 327,665 tons, and armed with 503 guns. The estimates of 1876-77 gave 3059 officers, 30,341 seamen, and 14,000 marines, and the expenditure as £11,091,392. See **BRITISH NAVY**.

Greece has 14 vessels, viz., 1 ironclad, 6 unarmoured steamers, and 7 sailing vessels, manned by 71 officers and 582 men, raised by conscription and voluntary enlistment. Expenditure, £69,996.

Italy has 81 steamers of 22,150 horse-power, viz., 11 ironclads, 38 screw-steamers, and 32 paddle-steamers, armed with 671 guns, and manned by 1271 officers and 11,860 men, with two regiments of marines, comprising 205 officers and 2700 privates. Expenditure, £1,912,947.

The *Netherlands* have 67 steamers, viz., 22 ironclads (of 4582 tons), 35 screw-steamers, and 10 paddle-steamers, armed with 521 guns, and manned by 627 officers and 4996 men, while the marines comprise 42 officers and 2121 privates. Both sailors and marines are raised by enlistment. Expenditure, £1,136,049.

Portugal has 37 vessels, viz., 1 ironclad, 19 unarmoured steamers, and 11 sailing vessels, armed with 168 guns, and manned by 238 officers and 3475 men. Expenditure, £287,853.

Russia has 108 vessels, manned by 1477 officers and 7217 seamen. Of this number 29 are ironclads, of 74,793 tons, and armed with 184 guns. The Baltic fleet consists of 77, and the Black Sea fleet of 9 men-of-war. The sailors are levied by recruitment and voluntary enlistment, and the term of service is nine years, the two last to be spent in the reserve. Expenditure, £3,586,574.

Spain, at the end of June 1875, had 89 vessels, viz., 7 ironclads, 74 unarmoured steamers, and 8 sailing vessels, armed with 914 guns, and manned by 399 officers, 9750 sailors, and 5500 marines. The navy is recruited from a naval conscription list of 72,000 men. Expenditure, £1,320,000.

Sweden has 131 vessels, viz., 14 ironclads (of 1013 horse-power), 20 unarmoured steamers, 8 sailing vessels, and 89 galleys, armed with 394 guns, and manned by 140 officers, 940 sailors, and 5051 marines (drawn from the naval bearing of 40,000 men); while *Norway* has 123 vessels, viz., 4 ironclads (of 600 horse-power), 28 unarmoured steamers, and 91 sailing vessels, armed with 156 guns, and manned by 104 officers, and 2289 men. Expenditure (1877), £397,300.

Turkey, at the end of 1875, had 20 ironclads, of 10,450 horse-power, armed with 145 guns, and 70 other steamers, manned by 30,000 sailors and 4000 marines. The crews are raised partly by conscription, partly by voluntary enlistment, and the term of service is 8 years. Expenditure set down in budget as £640,000. The actual annual expenditure, however, for naval purposes, including the construction of ironclads, is stated to have reached £3,000,000 in recent years.

The *United States* have 146 vessels, viz., 24 ironclads (of 26,895 tons), 67 unarmoured steamers, and 55 sailing vessels, transports, &c., armed with 1192 guns, and commanded by 776 officers. By the Naval Appropriation Bill (1876) the enlisted force was reduced from 8500 to 7500 men. Expenditure (1877), £2,754,871.

Navigation is the art of directing a ship along a pre-arranged course, and of finding its position at sea at any time. For the first a chart and mariner's compass (see COMPASS) are indispensable, except when the course is along a known coast. Amongst the ancients the compass was unknown, and consequently they were compelled to keep generally in sight of land. Their only guides were the stars, which of course failed them in stormy and cloudy weather. With the application of the magnetic needle to N., a new era began, an era rich in discovery (see GEOGRAPHY). Knowing the direction in which one place lay from another, the mariner could now direct his course from the latter to the former. To obtain this knowledge the chart was necessary; but even a chart would be useless unless the position of the ship at any instant were definitely known. The position of a point upon the surface of a sphere is determined by two co-ordinates. These co-ordinates on the earth's surface are called meridians and parallels, the former being great circles through the poles, the latter small circles parallel to the equator. Each meridian, whose angular distance from a fixed meridian gives the *longitude* of every point upon it, intersects each parallel, which similarly fixes the *latitude*, in one point and one point only. If the latitude and longitude (see LATITUDE AND LONGITUDE) of a point are known, the position of that point is fixed. To determine these co-ordinates is, therefore, the great problem of N., for knowing these the navigator can with the aid of chart and compass steer his course to any desired port or region. Now the latitude is equal to the altitude of the celestial pole above the horizon in whatever hemisphere the observer may be. If there were a star whose position was exactly that of the celestial pole, a single

observation of that star would be sufficient to determine the latitude. In neither hemisphere is this the case. In the northern, however, a star of the second magnitude known as Polaris is very near the pole, daily describing round it a small circle of $1^{\circ} 21'$ radius. An observation of this star will therefore give the latitude within $1^{\circ} 21'$ of error.

The meridian altitude of any celestial body (sun, moon, or star), whose distance from the pole at that date is known, gives by a simple calculation the true latitude. The polar distance of the principal heavenly bodies is given in the *Nautical Almanac*. Altitudes are taken by means of the Sextant (q. v.), an instrument invented by Newton, and first constructed by Hadley. The determination of the longitude is a more complicated process, and is obtained by comparison of the local time and the corresponding Greenwich time. Local time is most accurately obtained by observing the instant when the sun or a known star crosses the meridian. At sea, however, this method is not feasible; but instead, the altitude is observed when the heavenly body is out of the meridian. The latitude, which has been already determined, gives by a simple calculation the greatest altitude of the known star; and the difference between the greatest altitude and observed altitude affords the necessary datum for determining the local time. Greenwich time is usually taken from chronometers, but failing these, by 'lunars.' The *Nautical Almanac* gives several years in advance the calculated positions of moon among the stars for every third hour of Greenwich mean time; and by comparing these with the observed positions, the Greenwich mean time is ascertained. Works on N. contain elaborate rules, formulæ, and tables for reducing the observations; but sufficient has been here said to give a general idea of the methods usually employed in determining a ship's latitude and longitude. The value of the latitude, upon which the calculation of the longitude depends, is generally found by Dead Reckoning (q. v.) from previously determined positions; and for long distances dead reckoning is necessarily uncertain. Sumner's method of interpreting an observation of altitude is free from this uncertainty, inasmuch as it disregards totally the true latitude. Here, of course, the *Nautical Almanac* and a knowledge of Greenwich time are as indispensable as in the ordinary method. Knowing the time, the position of the sun, moon, or star at the instant of observation is known. With the point as centre in whose zenith the observed body is at the instant of observation, describe on the terrestrial globe a small circle whose arcual radius is the observed altitude. The vessel lies somewhere on that circle. A similar circle may be drawn for another star simultaneously, or for the same body several hours later; and the position will then be at or near one of the points of intersection of the two circles. Practically, all that is necessary is a portion of each of these circles drawn upon Mercator's projection according to known rules. Sir W. Thomson, by whom the method has been prominently put before the public, has published (1876) stereotyped tables, accompanied by a pamphlet of rules and illustrations for facilitating the application of Sumner's method. See Thomson's *Navigation Lecture* (published by Collins & Co., 1876). The intersection of the Sumner's *lines* gives at once the position, and therefore the latitude and longitude of the vessel. For details regarding the directing of a ship along a pre-arranged course see article SAILINGS. Under SIGNALS, the value of marine signalling is indicated. The best treatises in N. for use at sea are those of Inman, Norrie, and Kaper.

Navigation-Laws. The statute of the Long Parliament of 1651, confirmed in 1660 by the Navigation Act of 12 Charles II. c. 18., provides that no merchandise shall be imported into England except in a British built ship, navigated by an English commander, and of which three-fourths of the crew are Englishmen. The aim of this and of other 'protective' provisions of the Act was to encourage British shipping, by securing the carrying trade of the country to British ships and to British subjects. This selfish and short-sighted policy was followed by the United States of America, who passed their Navigation Act immediately on gaining their independence. In the trade between the two countries, it thus followed that the ships of each state were obliged to make the outgoing voyage in ballast. A perception of this waste of time and material at last proved to each country the impolicy of the system. A treaty was entered into in 1815, by which the ships of the two countries were placed on the same footing in the ports of England and of the United States, and all

discriminative duties levied on the goods conveyed were repealed on each side. A few years later five acts were passed which greatly mitigated the severity of our N.-L. with regard to foreign countries generally. Preference duties, however, continued to be levied; but in 1823 Prussia notified that until the British system was changed in favour of its ships, similar duties would be imposed on British ships entering Prussian ports. This led to the Reciprocity Acts, 4 Geo. IV., c. 79, and 5 Geo. IV., c. 1. These statutes authorised the Crown to allow the importation and exportation of goods in foreign vessels, at the same duties as were chargeable on British vessels, in favour of all countries according the similar privilege to British ships. Reciprocity treaties have been entered into between the United Kingdom and Germany, States of S. America, France, Austria, Holland, and Greece. The Merchant Shipping Act (q. v.) of 1854 amends and consolidates the whole statute law relative to merchant shipping.

Navigators' Islands. See SAMOAN ISLANDS.

Nawaub' (*Nāwāb*, properly the plural of the Arabic word *nāib*, 'a deputy,' but used honorifically in the singular), is a term applied throughout India to the viceroy or governor of a province under the Mogul Empire. It denoted the highest office under the Emperor; and consequently is now adopted by those feudatory chiefs in India who are Mohammedans. It is also frequently conferred as a mere title by the British Government upon meritorious Mussulman subjects. The corrupt form *Nabob* (said to be derived from the Madras pronunciation), was commonly applied about the middle of last century to those Englishmen who brought back easily-acquired fortunes from India by 'shaking the pagoda tree.'

Nawabgunge ('the governor's market'), the name of numerous villages and towns in India. The largest is the chief town of the district of Barabanki in Oude, 19 miles N.E. of Lucknow. Pop. (1869) 14,489. Another N. in the neighbouring district of Gonda carries on a large river trade with Bengal. In 1876-77 it exported food grains to the amount of more than 10,000 tons, including wheat valued at £28,000.

Naxos (Mod. *Naxia* or *Axia*), an island of Greece, the largest of the Cyclades, lies E. of Paros, in the *Ægean* Sea, nearly half-way between the coasts of Greece and Asia Minor. Length, 55½ miles; area, 171½ sq. miles; pop. (1870) 12,000. The surface is generally mountainous; in the middle *Zia* rises to 3290 feet, and near it *Koroni* to 3247. The plains and valleys yield abundant corn, wine, oil, cotton, figs, pomegranates, and lemons. N. exports salt and emery (in 1871, 2030 tons at £10). N. was in ancient times famed for its wine and marble, and here *Dionysus* was said to have found *Ariadne*, deserted by *Theseus*. It was early colonised by Athenian emigrants, was conquered in 540 B.C. by *Pisistratus*, by the Persians in 490, recovered its independence in 480, but did not again play an important part in history.—In N., the chief town, on the N.W. coast, are a citadel built by the Venetian Duke *Marco Sanudo*, and a square tower of the old palace of the Dukes, destroyed by *Babirusa*. It is the seat of a Greek bishop and a Catholic archbishop, and has 16 Greek and 4 Catholic churches, and 3 monasteries.—Another N., founded B.C. 735 on the E. coast of Sicily, S. of Mt. *Taurus*, by the *Chalcidians* of *Eubœa*, was the first Greek colony in that island. Six years after it sent colonies to *Catana* and *Leontini*. During the Sicilian Expedition N. aided the Athenians. In 403 it was destroyed by *Dionysius* of *Syracuse*. The survivors of the *Naxians* founded (358) the city of *Tauromenium*.

Nazarene, a name universally applied in the New Testament to *Jesus*, for his connection with *Nazareth* (Mt. xxvi. 71, Mk. x. 47, Lu. xviii. 37, Jo. i. 45, &c.), always with more or less of reproach (Jo. i. 46, cf. vii. 41), was afterwards applied to the first Christians as a term of contumely and scorn (cf. Acts xxiv. 5).

Nazareth (Arab. *En-Nāsirāh*), a town in the Turkish vilayet of Syria, lies in a valley girt by hills 400 to 500 feet high, 67 miles N. of Jerusalem and 11 W. of the Sea of Galilee. It contains a mosque, a huge Franciscan convent, attached to which is the Church of the Annunciation (rebuilt in 1620 on the site of the older building of St. Helena), a Maronite and a Greek church. The Mount of Precipitation and the site of the *Casa*

Santa (see *LORETO*) are pointed out. Estimated pop. (1871) 7000.

Nazarite, properly *Nazirite* (Heb. perhaps 'one separated'), among the Jews was a person of either sex under a particular vow, the regulations for which are given in Num. vi. 1-21, which, however, appear to imply a previously existing practice. The vow of the N. was:—1. To abstain from wine and all kinds of intoxicating drinks; 2. To refrain from cutting the hair of the head, because his whole person was consecrated to God, and could not be altered; and 3. To avoid all contact with the dead, even his nearest relations. The duration of the vow was fixed by the later Jewish canons as at least thirty days, but might be as much longer as was desired. See Ginsburg in *Kitto's Cyclo. of Bib. Lit.* (new ed. Edin. 1866); and Ewald's *Alterthümer des Volkes Israel* (Eng. transl. 1876).

Neagh, Lough, in the province of Ulster, Ireland, is the largest lake in the British islands, having a length of 18 miles, a breadth of 11, and an area of 153 sq. miles. It is 120 feet deep, receives from the S. the Upper Bann, Blackwater, &c., and is drained on the N. by the Lower Bann into the Atlantic. N. abounds in fish, and is haunted by waterfowl (the swan, heron, bittern, teal, &c.). Its waters at various parts are noted for their petrifying qualities.

Neal, Daniel, an English historian and Nonconformist minister, was born in London, December 14, 1678. After leaving Merchant Taylors' School he spent three years at the universities of Utrecht and Leyden. From 1706 till 1742 he was pastor of a Congregational Chapel in Aldersgate Street. He published a *History of New England* in 1720, and his best-known work, the *History of the Puritans* (4 vols. 1732-38; edited by Toulmin, with a Life, 1793; new ed. 1837; American ed. New York, 2 vols. 1844) was designed to extol the virtues of the Nonconformists. Mr. Green in his *History of the English People* (1875) says that 'besides its inaccuracies, it contains little which is not taken from the more colourless *Strype*.' N. died at Bath, April 4, 1743.

Neal, John, an American author, was born at Portland (then called Falmouth), Maine, August 25, 1793. He led a rough sort of life up till 1816, when, after failure in the dry goods trade, he threw himself determinedly into the study of law. He read through a seven years' legal course in twelve months, supporting himself by magazine contributions, and was finally called to the Maryland bar in 1819. Besides much miscellaneous literary work, he published *Keep Cool*, a novel, in 1817; a volume of poems in 1819, and no less than four novels in 1823. In 1824 he made a visit to England, where he remained three years, part of which time he was the guest of *Jeremy Bentham*. He published *Brother Jonathan* in 1825, and contributed largely to *Blackwood*. Afterwards he practised law, wrote books—*Authorship*, *Down-Easters*, &c.—and taught fencing and sparring in his native town till 1850, when he retired. Since then he has written *One Word More*, *True Womanhood*, a *Tale* (both semi-religious works), *Wandering Recollections of a Somewhat Busy Life* (1870), *Portland Illustrated* (1874), &c. M.'s writings are destitute of culture and taste, but display a slashing vigour, and are brightened with bursts of genius.

Neale, John Mason, born in London, 24th January 1818, graduated M.A. of Cambridge (1840), was ordained (1842), and became rector of Crawley, in Sussex, and Warden of Sackville College, East Grinstead (1846). At the latter place he founded the well-known Sisterhood of St. Margaret (1856), and there he died, 6th August 1866. N., while leaning to the Eastern Church, was a warm supporter of the 'Anglo-Catholic' party in the Church of England, as may be seen from his *History of the Holy Eastern Church* (4 vols. 1847-51), *History of the so-called Jansenist Church of Holland* (1858), *Essays on Church History* (1863), &c. He was an able hymnologist, and his *Medieval Latin Hymns* and *Hymns of the Eastern Church* (collected 1871) are widely popular.

Neander, Johann August Wilhelm, the greatest of Church historians, was born of poor Jewish parents at Göttingen, 16th January 1789. When about seventeen years of age (1806) he made a public profession of Christianity, renounced his Jewish name *David Mendel*, and called himself N. (Gr. 'new

man"). Devoting himself to sacred literature, he studied first at Halle, where he heard the lectures of Schleiermacher, and afterwards at Göttingen, where Gesenius was Professor of Hebrew, Stüdlin of Systematic Divinity, and Planck of Church History. In 1811 he settled at Heidelberg as a private tutor in the University, and began his remarkable career of instruction in Church History. The following year he was appointed extraordinary Professor of Theology; but his work *Über den Kaiser Julianus und Sein Zeitalter* (Leips. 1812), attracted so much attention that in 1813, at the age of twenty-three, he was called to a chair of Theology in the University of Berlin, where he remained till his death (14th July 1850). In this place for thirty-eight years he continued to exercise an ever-increasing influence, 'such as has rarely been wielded in modern times.' Students flocked from all quarters, even from foreign countries, to hear his lectures. While he showed himself an erudite scholar, a profound and original thinker, and an eloquent expounder in every branch of the wide domain of theology, his forte undoubtedly was the historical department, in which it was evident from an early period of his career that he had a real genius. The personal character of N. deserved all the praise that has been bestowed upon it. 'Untiring industry, a sagacity—within certain limits almost prophetic—a humble, ardent, life-pervading, rejoicing spirit of godliness, childlike simplicity, self-denying benevolence, a heart glowing and capacious enough for all the requirements of Christian friendship, but delighting especially to pour out its rich treasures of instruction and of sympathy upon the receptive souls of the young,' have been enumerated as its principal features. As has been said, it would be difficult to say whether the influence of his lectures and writings, or of his example on his students, who loved him as a father, has been the greater. His great work, which is unrivalled in its field, because it is drawn as carefully from original sources as if N. had had no predecessor, is his *Allgemeine Geschichte der Christlichen Religion und Kirche* (6 vols., Hamb. 1825-52). The most important of his other writings are *Geschichte der Pflanzung und Leitung der Christl. Kirche* (2 vols. Hamb. 1832); *Das Leben Jesu Christi* (Hamb. 1837), written in reply to Strauss; *Der Heilige Bernhard und sein Zeitalter* (Berl. 1813); *Der Heilige Chrysostomus* (Berl. 1822); *Denkwürdigkeiten aus der Geschichte des Christenthums* (Berl. 1822); *Antignostikus* (Berl. 1825); *Geschichte der Christlichen Dogmen*, published by Jacobi in 1856. English translations of most of these may be found in Bohn's 'Standard Library.' A complete edition of N.'s writings appeared at Gotha in 13 vols. 1862-66.

Nearp Tides. See TIDES.

Nearchus, a distinguished friend and officer of Alexander the Great, was born in Crete, but settled at Amphipolis in Macedonia, Strymon. Of his family and parentage nothing is known. In 329 B.C. he became attached to Alexander, and accompanied him throughout his campaigns. During the Indian expedition he received command of the fleet constructed on the Hydaspes. In spite of numerous natural obstacles, lack of knowledge of the country, adverse weather and threatened mutiny, N. eventually, by prudence, judgment, courage, and patience brought his expedition to a successful issue. He left the Indus 21st September 325, reached Susa in Persia February 324, immediately after Alexander's arrival, and there took part in the honours offered to the conqueror, being himself rewarded with a golden crown for distinguished services, and with the hand of the daughter of the Rhodian Mentor and Barsine, Alexander's former wife. To the last N. remained the steadfast friend and adviser of Alexander. Of his famous voyage he left a record, a transcript of which has been preserved by Arrian, and which indeed has furnished the latter with materials for part of his 'Indica.' See Schmieder's edition of Arrian's *Indica* (8vo, Hal. 1798), Dr. Vincent's *Commerce of the Ancients in the Indian Seas* (Lond. 1807), and Geier's *Alexandri Magni Historiarum Scriptores* (pp. 108-150).

Neath, a town in Glamorganshire, S. Wales, on the river N., near its mouth, and 8 miles E.N.E. of Swansea by rail. It is an important railway centre, and exports the copper, spelter, iron, tin, coal, coke, culm, and fine bricks produced extensively in the vicinity. A new tidal and floating dock was constructed at Briton Ferry, 2 miles from this town, in 1861. Historically N. is interesting as occupying the site of *Nidum*, a Roman

station, also for its ancient castle, destroyed in 1231, and, above all, for the beautiful ruins of N. Abbey, according to Leland, 'the fairest abbey in all Wales.' Pop. (1870) 10,060. N. with the other Merthyr-Tydvil boroughs sends one member to Parliament.

Neaves, Charles, Lord, was born in Edinburgh, 14th October 1800, educated at the High School, of which he became dux in 1814, studied with distinction at Edinburgh University, and was called to the bar in 1822. From 1841 to 1845 he was Advocate-Depute, from 1845 to 1852 Sheriff of Orkney and Shetland, and from 1852 to 1853 Solicitor-General. On the death of Lord Cockburn in 1853 he was appointed a Judge in the Court of Session, and in 1858 a Lord of Justiciary. He died 23d December 1876. N. was unquestionably a great lawyer. No man, it is said, knew so much about the criminal law of Scotland as he did; but what will most surely keep his memory green was the brilliant and sportive genius of the man, which found expression alike in finely critical prose and exquisitely witty verse. N. was a contributor to *Blackwood* from 1830 almost to his death. Steeped in classical scholarship, he was the reverse of pedantic. His Latin and Greek only gave point and flavour to the native vivacity of his spirit. The brightest effluence of his muse is seen in the volume entitled *Songs and Verses* (Edinb. 1868; last ed. 1875). Many of the songs, e.g., 'The Origin of Species,' 'Stuart Mill on Mind and Matter,' 'The Peppermint Bill,' 'Saturday at E'en,' 'Let us all be unhappy on Sunday,' are not only infinitely amusing, but are instinct either with the soundest sense or the healthiest social sentiment.

Neb-neb or Nib-nib, the pods of *Acacia vera*, used in Egypt and also imported into Britain for tanning.

Nebraska, one of the central states of the American Union, is bounded N. by Dakota, S. by Kansas and Colorado, E. by the Missouri River, which separates it from Iowa and Missouri, and W. by Colorado and Wyoming. Area, 75,905 sq. miles; pop. (1874) 230,007, exclusive of some 6000 Indians. The country, in great part rolling prairie, has a length from E. to W. of 412 miles and a breadth of 208, rises gradually in the W. towards the Rocky Mountains, and in the E. is amply watered by the Niobrara and the Platte or N., and by many smaller streams, of which the chief are the Great Nemaha, Little Nemaha, Weeping Water, the Republican, and the Big Blue—the last two affluents of the Kansas. The Niobrara forms the N. boundary, and the N., a majestic but unnavigable river, traverses the state from E. to W.; both are tributaries of the Missouri. The river-beds or bottoms are confined by high bluffs, and the soil is a rich, black vegetable mould from two to ten feet deep. Wild grasses grow luxuriantly in the bottoms and on the prairies, but the supply of timber, even along the rivers, is not abundant, and large quantities of trees have been planted throughout N. in recent years. N. is entered in the S.E. by a continuation of the great coal-basin of Iowa and Missouri, but the coal is too thin for profitable mining on a large scale. Proceeding westwards, the rocks are first Permian, then Cretaceous, and finally Tertiary, including large deposits of excellent lignite. Besides coal, the minerals are lime, sandstone, marble, gypsum, and especially salt. In the W. are many large salt-basins, one of which, in a district 12 by 25 miles in extent, is said to produce the purest salt in the world. The springs contain 29 per cent. of salt, and the mineral manufactured by solar evaporation is 98½ per cent. pure chloride of sodium. N. has a fine climate, the mean temperature at four stations in different sections of the state ranging between 101° and 130°, and the mean annual rainfall during the period 1863-69 being 30·36 inches. In 1874 nearly one-fourth of the land was under cultivation, and the yield of Indian corn was 3,500,000 bushels (value \$2,550,000); of wheat, 3,619,000 bushels (\$2,171,400); of rye, 32,000 bushels; of oats, 1,944,000; of barley, 355,000; of potatoes, 275,000; and of hay, 180,500 tons. The total value alone of the crops enumerated was \$7,166,200; but during the years 1873 and 1874 agriculture suffered greatly from droughts and the visitation of grasshoppers or locusts. In 1874 N. had 87,449 horses, 7615 mules, 229,469 cattle (return incomplete), 30,329 sheep, and 233,652 swine—total value, \$7,708,044. Lincoln (pop. 1870, 2441) is the capital; the largest cities are Omaha and N. city. In 1876

there were throughout the state 1150 miles of railway. N., a part of Louisiana territory ceded to the United States by France in 1803, was admitted to the Union in 1867, and placed under a new constitution in 1876.

Nebuchadnezzar (in the cuneiform inscriptions, *Nabukudur-ussur*, 'Nebo is the protector against misfortune'), the greatest of the Babylonian monarchs, was born about 644 B.C., and succeeded his father, Nabopolassar, in 604. Having already defeated Pharaoh-Necho, king of Egypt, at Circerium (606), he now turned his arms against Palestine and Syria. He sacked Jerusalem and destroyed the Temple of Solomon (586), sending the greater part of the Jewish nation into captivity at Babylon, and captured Tyre (585), after besieging it for thirteen years. Strabo tells us that he even extended his conquests as far as Spain, by way of Libya. From the cuneiform inscriptions we learn how he beautified his capital and founded the cities of Cutha, Chilmad, and Teredon, and the book of Daniel relates his four years' fit of lycanthropy, and his erection of an image of Merodach in the plain of Dura. M. died in 561, and was succeeded by his son, Evil-Merodach. See Rawlinson's *Five Great Monarchies* (4 vols. Lond. 1862-67).

Nebulæ (Lat. 'thin cloudy mists') are celestial bodies which are distinguished from planets and stars by their generally hazy cloud-like appearance. Of the comparatively few visible to the naked eye, the most important are the great nebula in Orion and the Magellanic clouds of the southern hemisphere. The milky way is not a true nebula, but is merely a cluster of stars, easily resolvable by a telescope of moderate power. When Sir W. Herschell applied his forty-foot reflector to the task of sweeping the heavens, many nebula-like bodies were resolved into star-clusters, but many were still irresolvable. Some of these the giant telescope of Lord Rosse has since resolved; but the discovery of many more of these objects proved the inability of the telescope to decide whether all N. were star-clusters, or whether there existed in the universe diffused masses of gaseous material, the possible basis of a future system like our own. The regular forms which many of the N. assumed, however, argued in favour of the latter hypothesis, that there were bodies which could not be classified with stars, planets, comets, or meteors. Many form distinct spirals, others circular or elliptic rings arranged concentrically; and intermediate forms are recognisable. The most interesting of all are perhaps the so-called planetary N., which, from their sharply-defined disks and frequently nucleated appearance, have been regarded as a stage in the development of a planetary system—such a stage as our solar system is believed to have passed through in some remote epoch. The spectroscopic (see SPECTRUM ANALYSIS) has fully borne out this hypothesis, and in the hands of Huggins, Frankland, Lockyer, Secchi, and others, has revealed that there are bodies distinct from star-clusters, to which therefore the name N. is now restricted. Stars give a continuous spectrum crossed more or less by dark absorption lines or bands. N. give no continuous spectrum, or at most a faint one; but they give one or more bright lines, some of which have been identified with the bright lines of known substances. In all one of the lines of nitrogen seems a constant feature; and another line of frequent occurrence has been identified with the violet line of hydrogen. A third line, not identified with any known substance, is also often present, and sometimes a fourth makes its appearance. The reason why all the lines of nitrogen and hydrogen do not appear is probably because of the peculiar conditions of temperature and pressure. Experiments upon Geissler tubes filled with various gases show that pressure and temperature are important elements in determining what lines should appear in the spectrum of the glowing gas. Frankland and Lockyer have given it as their opinion that the temperature of N. is generally lower than that of our sun; Secchi and Wülnner, however, incline to the contrary opinion. See Schellen's *Spectral Analyse* (1870).

Necessity is a term used to denote the fixed relations of cause and effect which exist between physical and mental phenomena, including (according to the tendency of modern speculation) the human volitions. The primitive conception, however, was that of an ill-understood but tremendous Power against which it was in vain for man to struggle. This might be the vengeful Fate or the impersonal Abstrac-

tion, of which the Greek tragedians and philosophers have made such ample use. On the one hand the idea of causation is as universal as that of Existence, as nothing can be conceived without express or tacit reference to its effects: on the other hand, the particular causes which are to combine in controlling every moment of the individual life can never be foretold, and therefore to some extent remain mysterious and inevitable. N. was therefore a Faith, involving religious emotions of the most powerful kind: it included Predestinarianism and the other forms of Fatalism. As a metaphysical conception, N. correctly indicated the connection of verbal identity which existed between Cause, defined as the ideal sum of similar effects, and Effect, defined as part of the contents of the idea cause. This is the N. which occurs in syllogistic reasoning on the principle *dictum de omni et nullo*, and in the mathematical sciences, so far as the results flow from the definition and axioms. After Hume's analysis, however, it was seen that whatever may be the case as regards the general ideas, formerly called innate and necessary, mere mental connection does not explain the supposed necessity of invariable sequence in the case of a newly observed effect. Hume denied that there was any *nexus* except the inference, more or less probable, which the mind drew from experience. The Intuitionist School fell back on the ideas of Cause and Power, and pointed out that these possessed qualities of universality and necessity which admittedly could not be generated by the experience, necessarily limited, even of the whole human race. To this it was replied that the existence of such ideas was easily accounted for by the history of the human mind, which is emotional as well as intellectual, and which, even so far as purely intellectual, does not tend, except under the conscious guidance of science, faithfully to mirror the uniformities of nature. An ethical and theological interest was imparted to the discussion by its extension to the human will, from which the Intuitionists professed to derive their intelligible idea of power adequate to an effect, but which the Positive or Experience School maintained to be subject to the ordinary laws of causation. See CAUSE, FATALISM, FREE-WILL.

Neck'ar (Lat. *Nicer*), a river in Germany, and one of the chief affluents of the Rhine, rises in the Schwarzwald, on the frontier of Baden and Württemberg, flows in a northerly direction through a beautiful vine-clad valley, receives from the left the Enz and from the right the Fils, Rems, Kocher, and Jaxt, passes Tübingen, Heilbronn and Heidelberg, and joins the main stream at Mannheim after a sinuous course of 240 miles, only half of which is navigable.

Neck'er, Jacques, a great French statesman, was born at Geneva, 30th September 1732. His family is said to have been an English Protestant one driven from Ireland by the Marian persecution. N. had a long commercial career in the Parisian banking houses of Vernet and Thellusson. He enjoyed the confidence of the Minister De Choiseul, to whom his firm rendered important financial services, and defended the privileges of the *Compagnie des Indes* against the criticisms of the Abbé Morellet. Retiring from business, N. began to bid for the post of Comptroller-General, to which, however, Turgot was appointed. By an ill-written *Éloge* upon Colbert he obtained a prize from the French Academy; and in *Essai sur la Législation et le Commerce de Grains* (1775) he opposed the abolition of all restrictions which Turgot had laid down as his programme. The State, he said, was bound to regulate the trade, and to protect poor consumers against the landed proprietors. Turgot was dismissed after the bread riots, and N., though an alien and a Protestant, succeeded the imbecile Clugny as Director-General of Finances. With war expenses and an annual deficit of more than 30 million livres, he began by borrowing nearly 500 millions, and addressed himself honestly to the task of reforming a corrupt administration and an inequitable basis of taxation. He suppressed many ridiculous offices, urged strongly the formation of provincial assemblies to deal with the feudal imposts, obtained an advance of 15 millions of rent from the tax-farmers, and in 1780 published his *Compte Rendu*, which showed a surplus of 10 millions by omitting all extraordinary expenses. This publication offended the Court very much, and N., on being refused by Maurepas a seat in the Council of State, resigned and retired to St. Ouen, where he wrote his *Essai sur l'Administration des Finances*, a work of great popularity and much historical value. The blunders of Calonne and Brienne

recalled him in 1788 to the Director-Generalship, with a seat in the Council. He found the Exchequer empty, the Government without credit, and a famine in the land. His appearance sent up the Funds 30 per cent. in a single day, and he lent France two million livres of his own money. N., however, had no wide political views, although he had studied the British Constitution. He opposed the demand of the States General for a double representation of the *tiers état*, and convoked the notables. When the struggle began between the throne and the people he was unceremoniously dismissed, but was recalled by acclamation after the taking of the Bastille. His political indecision now gave the lead entirely to Mirabeau, and he unwillingly saw the property of the clergy confiscated, and the issue of assignats. N. withdrew to Coppet, near Geneva, in September 1790. Here he wrote on his own administration and on the Constitutions adopted in '91 and '95, he also published a work *De l'Importance des Opinions Religieuses*. He died 9th April 1804. N. was skilful in monetary matters, and a man of high principle and good heart, but no statesman. His life was written by his daughter, Mme. de Stael (q. v.), and his *Œuvres Complètes* were published in 17 vols. (Par. 1822).

Necklace, a jointed or flexible ornament encircling the neck. It was worn by both sexes among the nations of antiquity, but its use is now confined exclusively to females of all races. It was regarded peculiarly as a bridal ornament by Grecian and Roman females. Very diverse materials have been, and still are, employed for making necklaces. Degraded tribes string together seeds, fruits, or shells, while coral, pearls, and beads of ivory, glass, porcelain, amber, and jet furnish materials for necklaces among civilised nations. Valuable neck ornaments are likewise made of precious metals and gems. For beauty and variety of form the granulated gold necklaces of the Etruscans have never been surpassed. See DIAMOND NECKLACE.

Neck-Mould or Moulding, in Architecture, a small convex moulding at the junction of the shaft and capital of a column.

Necromancy (from Gr. *nekros*, 'dead,' and *manteia*, 'prophecy') is a method of divination by conjuring up the dead. Its origin belongs to the most remote times. The story of the Witch of Endor (see 1 Sam. xxviii. 7-25), the *Necromanteia* of Homer's *Odyssey* (bk. x.); and bk. vi. of the *Æneid* of Virgil may be consulted on the subject of N. N. is one of the fast-disappearing superstitions of the past. In ancient Greece, especially in Thesaly, Phocis, &c., it was a profession. In Roman times it was interdicted by Constantine, and subsequently placed under the ban of the Church. See DIVINATION, SPIRITUALISM, and the special articles on cognate subjects.

Necropolis (Gr. *nekros*, 'dead,' and *polis*, 'city'), a name originally applied to the western suburb of Alexandria, in which the Catacombs (q. v.) were situated, and hence extended to the burial-places of the ancients generally, as the N. of Thebes, of Memphis, and Abydos. In modern usage the term is synonymous with Cemetery (q. v.), e.g., the N. of Glasgow and of Woking.

Necrosis (from Gr. *nekros*, 'dead') is the term applied to the total death of a portion of bone. N. is generally caused by inflammation, or by loss of blood supply. The dead bone, if not exposed to the air and bathed in the products of putrefaction, becomes white; if cut into, it does not bleed; it is denuded of its periosteum; and its surface is smooth, hard, and ringing when struck. The inflammation, which extends to the neighbouring bone, leads to condensation and periosteal deposits, both on the surface of the living bone, and especially over the dead bone, so that the latter is covered over or *invaginated* by a sheath of periosteal bone. N. is distinguished from *Caries* (q. v.), or the ulceration of bone, and its disintegration in molecules, the latter being the stage which succeeds the softening stage of osteitis when the inflammatory process proceeds towards disintegration instead of being arrested and repaired. N. is similar to the process of *gangrene* in the soft parts, and *caries* to that of *ulceration*. The treatment of N. is, as a general rule, to wait until the bone is loose, and then to remove it. The mode of removal depends upon the nature of the part affected and the extent of the disease.

Nectar (prob. from *ne* 'not,' and *kteinō*, 'I kill') was among the Greeks held to be the drink of the gods, as ambrosia was their food. Homer describes it as red in colour, and says it was poured out like wine, and mixed with water for use. N.

was withheld from men, being an elixir of immortal life. Later it acquired the notion of fragrance, and the adjective *nectarous* ('nectarous') is frequently used for 'sweet-smelling.'

Nectarine, a smooth-skinned variety of the Peach (q. v.).

Nectary, in Botany, is a term applied to any part of a flower, which is specially formed for the secretion of honey or saccharine fluid. Instances of nectaries are afforded by the shallow pits at the base of the perianth-leaves of the crown-imperial, the hollows concealed at the base of the petals of ranunculus, the glands between the stamens of the grape-vine, the spur of the columbine and of many species of orchis, the appendages to the two stamens of viola, &c. The N. is of great importance in the economy of nature, as the secreted honey naturally attracts insects, and they, visiting flower after flower, convey the pollen of one to the stigma of another, thus effecting fertilisation. In structural design necessary to accomplish this cross fertilisation, the special flower and its special insect visitor are adapted to each other. By Linnæus the word N. was used to imply almost any abnormal structure in a flower, irrespective of its being a honey-gland.

Needle-Gun. See BREECH-LOADING ARMS.

Needles are instruments used for sewing together textile fabrics, leather, skins, furs, and other materials, the nature of which permits of separate pieces being sewed together with thread. The needle, in one form or another, is of the highest antiquity, as is obvious from the fact that remains of sewed garments and a rude kind of bodkin or needle of bone are found among the pre-historic remains of various countries. To the present day the Esquimaux use N. of bone for sewing together the skins which form the garments they use. Although N. generally consist of straight pieces of steel wire, having a hole or 'eye' through one extremity, and brought to a fine sharp point at the other, yet for various purposes the form of the needle is much modified. Thus the essential feature of the needle of any sewing machine consists in the eye being brought as near as practicable to the point, and therein indeed lies the peculiarity on which the invention of the sewing machine depended. The N. of many sewing machines are curved, and for surgical purposes, packing, and upholstery use, curved N. are also employed. In some 'overhead' sewing machines now in use spiral N. are employed.

The needle manufacture, combined with the allied industry of fish-hook making is, in Great Britain, almost exclusively confined to the town of Redditch, and, as conducted at the present day, it is a pursuit in which remarkable manual dexterity is combined with very perfect instruments and appliances. As will be obvious from the following brief outline of processes, the simplest needle passes through many hands and stages before the piece of drawn steel wire of which it is fabricated is turned out ready for use. Steel of the finest quality, drawn into wire of suitable gauge for the various sizes of N. is the raw material, and it is first cut into lengths suitable for two N. To straighten these lengths several thousands are packed within two iron rings, which run in grooves on a flat iron table. By running the bundle back and forward several times under friction applied between the rings, the whole of the wires quickly adjust themselves in a perfectly parallel position. Both extremities are next ground to a point on small grindstones, the workmen dexterously holding a number parallel at one operation against the stone, moving them round so as to have the points uniform by a motion of the thumb. With these lengths of wire so sharpened at both ends, the next operation consists in piercing the eyes. By means of the stroke of a falling die a bulge is produced in the centre of the wire, at each side of which there is at the same time formed a small groove. The bulge is the dividing line of the two needles, and the grooves are the depressions in which the eyes are next formed. The piercing of the eyes is done by means of a hand screw-press, in the descending arm of which there are two steel points or cutters of the exact size of the eye to be made. The prepared wire being placed in position, the arm is brought down, and steel points penetrate the wire at the upper extremity of each groove. Through these pierced eyes a fine wire is next run, and a considerable number of the double needles are thus spitted or strung together. With a file the burr or bulge at the centre is next smoothed off, and the wires being now weakened at the centre, they are at this stage broken

across, thus leaving two rows of rough needles strung on wire. The points of one row are now firmly grasped in a hand-vice, and the heads are rounded and smoothed by filing, after which the wire is withdrawn. They are now ready for hardening and tempering by the ordinary processes, and then they are scoured or cleaned by making up bundles of 50,000 or more, on which a mixture of emery, soft-soap, and oil is sprinkled, the whole being lightly tied up in a canvas cover. The bundles are submitted to long-continued friction by rolling back and forward under heavy rollers in a scouring machine. This process is repeated several times, and on its completion the N. are washed with soap and water, and dried by working in a revolving box among bran. At this point the N. are gone over and arranged so that their points lie in one direction, the broken and defective specimens are picked out, and they are next 'handed' or sorted into lengths. The eyes are next 'blued' or softened for drilling, and drilled or worked on a small drill into a smooth rounded form, and finally they are polished on emery wheels—the polishing being done on three successive wheels fed with emery powder of increasing degrees of fineness. The N. are now practically complete, and only the papering and mounting of them remains to be done. In the grinding process the same unhealthy conditions prevail which are found in cutlery grinding; but by the adoption of the suction fan over the grindstones the evil can to a large extent be obviated.

Neem Tree. See MELIACEÆ.

Neemuch (*Almach*), an important British military station in Central India, within the territory of Scindiah, the Mahratta Rajah of Gwalior, 1476 feet above the sea, 155 miles N.W. of Mhow and 371 S.W. of Delhi. It was acquired from Scindiah in accordance with the treaty of 1817. The cantonments are large and healthy.

Neerwinden, a village in Belgium, province of Liège, where the French under Marshal Luxembourg defeated an English, Dutch, and Austrian army, 29th July 1693, and Dumouriez was worsted by the Austrians and Prussians, 18th March 1793. Pop. (1873) 423.

Negapatam, a town in the district of Tanjore, Madras, British India, on a mouth of the river Cauvery, 160 miles S. of Madras. Pop. (1871) 48,525. Many of the inhabitants are descended from the early Dutch and Portuguese settlers. The town is well laid out and airy. It is now the terminus of a branch of the S. Indian Railway. There are manufactures of cotton, silk, and oil, and some ship-building. There is also a large traffic in rice, &c., chiefly with Ceylon. In 1874-75, the value of the exports was £485,371; of the imports, £320,138.

Negative, in Photography, signifies a picture that exhibits, by transmitted light, the lights and shadows of the model reversed, the natural whites appearing as blacks and vice versa. The method of taking a collodion N. on glass is as follows: The plate, perfectly clean, is coated with iodised collodion, and then immersed in the sensitising nitrate of silver bath. After exposure in the camera, the plate is treated with the developing protosulphate of iron solution, which renders the lights and shadows in reverse arrangement to nature. The picture is washed with water, and if it be feeble it is submitted to the intensifying action of the citropyrrogallol acid solution with a few drops of nitrate of silver added. On re-washing, the picture is fixed by removing the unaltered iodide of silver by means of a solution of hyposulphite of soda or cyanide of potassium. All traces of the fixing agent are removed with water, and the picture is then dried and varnished. For the manner of obtaining from this N. positive proofs on paper, with the lights and shadows as in nature, see POSITIVE PRINTING.

Negative Quantities, in Algebra, may be defined as quantities which when added to equal and positive quantities give zero as result. Thus $-a$ is a negative quantity, and is such that

$$-a + a = 0$$

A negative quantity is therefore zero diminished by an equal positive quantity; and hence N. Q. are of necessity less than zero. If we consider a as a directed quantity or vector, then the expression $-a$ represents a line equal to $+a$ in length, but directly opposite in direction. Hence if the transit from O to A is represented by $+a$, the transit from A to O will be repre-

sented by $-a$; and since $O A + A O$ evidently result in no displacement, the equation $+a - a = 0$ holds good with this extension of signification. This was the step partly taken by Descartes in his analytical geometry, and completed by Hamilton in his Quaternions (q. v.). In algebra we have $-a \times -a = +a^2$, so that $\sqrt{a^2} = +a$ or $-a$. What then is the signification of $\sqrt{-a^2}$ or $a\sqrt{-1}$? This question has been fully answered by Hamilton, who discovered in $\sqrt{-1}$ a unit-vector or directed line in space whose length is the arbitrary unit. See VECTOR.

Negligence, in Law. Every man is legally bound to take care that he does not injure his neighbour. Therefore when a man receives an injury to his person or property by the fault of another—whether the fault be of omission or of commission, whether wilful or by N.—the law will give damage for the injury sustained.

Negotiation is the procedure which the holder of a Bill of Exchange (q. v. under BILL) must follow to procure acceptance of it and payment when it falls due. See also ACCEPTANCE, DISHONOUR.

Negrais, a small island which gives its name to a headland in British Burmah, bounding the most W. mouth of the Irrawaddy, in the district of Bassein. A British settlement was established here as early as 1687. After having been more than once abandoned and reoccupied, it was attacked by the Burmese in 1759, when all the Europeans were killed. It is said to afford a very safe harbour, and there is a fine lighthouse on the adjacent reef of Alguada.

Negroes (Span. *negro*, 'black'; Lat. *niger*), the ideal type of the negroid division of mankind (see ETHNOLOGY), occupy the Sudan, Upper and Lower Guinea, Senegambia, and the eastern portion of tropical Africa. Spread over so vast a district, and broken up into countless tribes, they exhibit many varieties of colour and physique, while sharing the characteristics of dark eyes and complexion, black woolly hair, a broad flat nose, coarse lips, and a dolichocephalic, prognathous skull. According to American ethnologists, the standard negro skeleton is heavier, and the skull 5 oz. lighter, than that of the white. With the Australoid races, the negro stands on the lowest step of natural development. Their powers of keen observation bear fruit in ape-like imitation, their sociability vents itself in excessive talkativeness, a quick susceptibility to sorrow, followed by as speedy forgetfulness; their religious instincts are purely emotional, and their dexterity and good-humour are counterbalanced by greediness, vanity, and vindictiveness. The chief negro races are the Mandingoes (q. v.), Fellata (q. v.), and the natives of Ashanti (q. v.), Congo (q. v.), Dahomey (q. v.), Angola (q. v.), and Sierra Leone (q. v.). See SLAVERY; and Waitz, *Die Negervölker und ihre Verwandten* (Leips. 1860); Oberländer, *West Africa* (Leips. 1874); De Compiegne, *L'Afrique Équatoriale* (Par. 1875); R. Hartmann, *Die Nigritier* (1 vol. Berl. 1876); and the works of Livingstone, Barth, Rühl, Schweinfürth, &c.

Negro Minstrelsy, a kind of music—simple words set to simple airs—which originated with the slaves of the Southern States of America. The troupe of 'Christy's Minstrels,' formed by E. P. Christy at Buffalo in 1842 to popularise N. M., has produced a host of bones and banjo imitators both in America and in England; the most famous in this country being the 'Moore & Burgess Minstrels' of St. James' Hall, London. Such minstrels are seldom coloured men, although the farce of blackening the face is kept up, and their performances are for the most part only amusing and broad caricatures. The 'Jubilee Singers,' a troupe of male and female freedmen, who have sung their crude but joyful hymns in this country several times since the abolition of slavery, are much truer exponents of a form of N. M.

Negropont. See EUBÆA.

Negundo, a Japanese and N. American genus of *Aceraceæ*, differing from the Maples (q. v.) by having pinnate leaves. *N. fraxinifolium*—the so-called ash-leaved maple—a native of the United States, attains a height of about 50 feet, and is rich in saccharine sap. In California it is used extensively as a shade tree.

Negus, a drink named after its originator, Colonel Negus, and made by diluting port or sherry wine with twice its bulk of

hot water, sweetening with lump sugar, and flavouring with lemon and grated nutmeg.

Nehemiah (Heb. 'comforted of Jehovah'), the Jewish patriot, was the son of Hachaliah (N. i. 1), and during the Babylonian exile was raised to the post of cup-bearer (i. 2) to Artaxerxes (Longimanus, B.C. 465-424). Owing to intelligence he received regarding the distressed condition of his brethren at Jerusalem he proceeded thither with authority from the king (B.C. 445; N. ii. 1), and in spite of the opposition of the Persian officials and those around them, succeeded in getting the walls completed; and then ruled as Persian governor in Judah for twelve years, till the thirty-second year of Artaxerxes (ii. 1-vii. 3, cf. v. 14). At this time he paid a visit to Babylon (xii. 6), but soon returned to Jerusalem, and set himself to reform certain abuses among the people, as withholding the dues of the Levites, profaning the Sabbath, and marrying foreign wives. The Book of N. is so intimately connected with that of Ezra that the Jews comprehended both under the name of the Book of Ezra, or the First and Second Book of Ezra (LXX). The two comprise the history of the Jews from the first year of Cyrus (B.C. 536) to the thirty-second of Artaxerxes, a period of 100 years. The Book of N. is divided into three sections: i.-vii., viii.-x., and xi.-xiii. In the first and last, which are similar in style, N. speaks in the first person, as the author; in the middle section, which besides is different from the other two in its whole style, he is spoken of in the third person. Accordingly it has been thought that the third section originally followed the first, and that the middle one was inserted by a later hand. Chapter vii., too, as he says himself (cf. v. 5), was not written by N., and one or two passages in the third section, e.g., xii. 1-26, 47, are thought also to have been altered or inserted, probably by the writer of the middle section.

Neilgherry Hills (*Nilgiri* = 'blue mountain'), a range, or rather mass of hills in a triangular form, in S. India. They form a sort of junction between the E. and W. Ghats, their greatest length (40 miles) being from S.W. to N.E. The highest peak is Doddabetta, near Ootacamund, 8760 feet above sea level. Their rocks are of primary formation, granite, quartz, gneiss, &c., broken through by dykes of basalt. There is little forest, the most conspicuous tree being the rhododendron. The temperature is very equable; the thermometer rarely rising above 76° in the hottest months (April and May), and rarely sinking to the freezing point in December and January. The tract of the N. II. was acquired by the British in 1803. The first European built his house at Ootacamund in 1820. There is now a branch of the Madras Railway to Metapoliun, close to that town. The hills are sought not only for their salubrious climate, but also for the valuable products which British enterprise has introduced. Coffee is annually exported from the neighbourhood to the amount of £600,000, and there is a little tea cultivation. Cinchona was introduced in 1862 at the instigation of Mr. C. Markham. Apart from private gardens, there are now 1000 acres planted with more than 2,000,000 cinchona trees, the property of Government. The experiment has proved a success, and Indian fevers are now cured with cheap Indian quinine. In all there were, in 1874-75, 13,000 acres under coffee, 3000 under cinchona, and 2000 under tea. Potatoes, garlic, and onions are also grown for export. There is a botanical garden at Ootacamund, and the Forest Department yields a revenue of £7000.—The district of the Neilgheries, which is co-extensive with the hills, has an area of 749 sq. miles; pop. (1871) 49,501, of whom 1339 are Europeans and 796 Eurasians. Among the aboriginal tribes are the Todas (q. v.). The chief town is Ootacamund (q. v.), and there is a military depot at Wellington for the accommodation of 1300 men. See *Primitive Tribes of the Nilagiris*, by J. W. Brecks (Lond. India Museum, 1873, abundantly illustrated by photographs).

Neilgherry Nettle is a name given to one or more species of *Girardinia*, natives of India. The genus differs from the nettles proper by having alternate instead of opposite leaves. The long, white, sharp, stinging hairs cover the whole plant, and their sting is very painful. From the fibre of the stem of *G. heterophylla* a sort of cordage and cloth is manufactured in Sikkim, and from *G. Leschenaultiana* a fine silk-like fibre that can be spun into a beautiful soft thread is procured. The process of separation is by boiling or by maceration.

Neill, James George, General, one of the heroes of the Indian Mutiny, was the son of a Scottish gentleman of good family,

and was born in 1810 in the neighbourhood of Ayr. Before he was seventeen he joined the 1st Madras European regiment, now II. M. 102d Fusiliers, with which regiment his name is ever associated, and of which he wrote an *Historical Record*. He served through the second Burmese War of 1853, and in 1855-56 was appointed second in command of the Anglo-Turkish Contingent. In April 1857 he returned to Madras as Colonel of his old regiment, and next month was summoned to Calcutta by the news of the Mutiny. His were the first troops to proceed up country, and his resolute treatment of the railway officials at Howrah has become a household story. He arrived in time to save Benares and Allahabad, and followed Havelock into Cawnpore, where it became his duty to inflict condign punishment for the massacre. He was killed while leading his brigade in the street-fighting of the first relief of Lucknow on 25th September 1857. A statue has been erected to his memory in the town of Ayr. See *Lives of Indian Officers*, vol. ii. by Sir J. W. Kaye (Lond. 1867).

Neisse, a fortified town of Prussia, province of Silesia, situated in a marshy district, at the confluence of the Glitzer, N., and Biela, 30 miles S.W. of Oppeln by rail. It has large military establishments, barracks, magazines, &c., important manufactures of arms, chemicals, tobacco, linens, and woollens, and extensive breweries and distilleries. Pop. (1875) 19,811, including 4075 soldiers.

Nejed, or **Nejd**, the central tableland of Arabia, is surrounded on three sides by the great sand-desert of Dhiana, and is mainly occupied by the Jebel Tuweik range, which, nowhere exceeding 5000 feet of elevation, is intersected by a perfect network of fertile valleys and watercourses, dry, except in the rainy season. The heights are covered for a great part of the year with rich grass. The Wahabis (q. v.) form the bulk of the population. Their capital, Riad, is estimated by Palgrave to have 40,000 inhabitants, who live by agriculture and horse-rearing. See Palgrave's *Narrative of a Journey through Central Arabia* (Lond. 1865); and Pelly, *A Visit to the Wahabee Capital*, in the *Journal of the Geographical Society* (1866).

Nejin or **Njeshin**, a town in the government of Tchernigov, Russia, on the Oster, a branch of the Dnieper, 80 miles N.E. of Kiev by rail. It has a cathedral, nineteen other churches, a lyceum, several large factories, and an important trade in tobacco of a fine quality. Pop. (1870) 21,590, of whom many are Greeks.

Nellore, the chief town of the district of the same name in the Madras Presidency, British India, on the right bank of the Pennair river, 8 miles from the sea, and 107 miles N. of Madras. Pop. (1871) 29,922. The site is high, and the streets are irregularly built; the walls, once formidable, are now in ruins. Interesting remains have been discovered, and Roman gold coins of Trajan, &c., were dug up in 1787. The Pennair is here crossed by an *anicut* or weir for irrigation.—The district of N., which lies between the E. Ghats and the Bay of Bengal, has an area of 8462 sq. miles, and a pop. (1871) of 1,376,811. The crops are rice, millets, ragae, gram, and indigo. The breed of cattle is good, having been much improved by an annual exhibition held at Addanki, in the N. of the district. The manufactures are indigo, cotton cloth, and fine muslin. The Government monopoly of salt annually produces about £120,000. There is a small coasting trade, and a navigable canal southwards to Madras.

Nelson. 1. A district and formerly a province of New Zealand. It occupies the N.W. portion of the Middle Island, and has an area of 10,270 sq. miles. It is for the most part rugged and mountainous, and derives its chief importance from its mineral wealth, which exceeds that of any other district of the colony, though at present it is very imperfectly developed. The first discovery of gold in New Zealand was made in N. in 1856, since which date large quantities of that metal have been obtained, principally in the basin of the Buller (q. v.) river. Good coal is found in great abundance, and valuable deposits of hematite are beginning to be worked. Silver, copper, manganese, and chrome are also obtained. The principal towns are N., Greymouth, Westport, and Collingwood. The population of the district at the census of 1874 was 22,566, and at the end of 1877 was probably 28,000.—2. An episcopal city, the capital of the above

district, charmingly situated on the eastern shore of the great inlet known as Blind Bay. It enjoys a delightful climate, but has a limited trade, though there are manufactures of cloth and leather. Pop. (1874) of the municipality, 5660; with the suburbs, 10,000.

Nel'son, Hora'tio, a kinsman on the mother's side of Horatio Walpole, was born at Burnham-Thorpe, a Norfolk village, of which his father was rector, September 29, 1758. After some years' schooling at Norwich and North Walsham, he went to sea with his maternal uncle, Captain Suckling (1771), acquired a passing dislike to the navy on board a West Indianman (1772), and was the only boy who served in the Polar expedition of Commodore Phipps (1773). He was next rated midshipman in the *Seahorse* on the East Indian station, was invalided home (1776), and having passed his lieutenant's examination (1777), rose to be first lieutenant of the *Bristol*, commander of the *Badger* (1778), and post-captain of the *Hitchinbrook* (1779). In 1780 he distinguished himself in an expedition up the San Juan, and, one of 380 survivors out of 1800 men, returned home crippled by dysentery. From 1781 to 1783 he commanded the *Albemarle*, and from her was appointed to the *Boreas*, on the Leeward Islands station, where by his enforcement of the Navigation Act and seizure of four American traders he nearly exposed himself to an action for £40,000 damages, and where he married a Mrs. Nisbet, March 11, 1787. Paid off in the autumn, N. lived at his father's parsonage till, on the eve of the Revolutionary War, he was commissioned to the *Agamemnon* (1793), and sailed under Lord Hood for the Mediterranean. Here at Naples he first met Sir William and Lady Hamilton, captured Bastia with 1200 against 4000 men (1795), lost an eye at the siege of Calvi, and in Hotham's action with the Toulon fleet (1795) took the *Ca Ira*. He hoisted the commodore's pennant in 1796, and at the battle of Cape St. Vincent (February 14, 1797), in defiance of Jervis' orders, brought his ship the *Captain* into action with seven Spanish first-rates, boarding the *San Nicolas* of 80 and the *San Josef* of 112 guns to the cry of 'Westminster Abbey or victory!' Already promoted rear-admiral, N. received the Order of the Bath and the freedom of the city of Norwich; and now shifting his flag to the *Theseus*, commanded the inner squadron at the blockade of Cadiz, where, to use his own naïve words, his 'personal courage was more conspicuous than at any other part of his life.' His next achievement—a gallant though unsuccessful attack on Santa Cruz (July 24)—cost him his right arm, but won for him a pension of £1000 and the freedom of the cities of London and Bristol. Up to this date N. had been in engagement with the enemy upwards of 120 times. On April 30, 1798, he was despatched to watch the Toulon expedition, which he came up with in Aboukir Bay. The Battle of the Nile (August 12), in which thirteen English vessels of 1012 guns engaged seventeen French of 1190, resulted in the annihilation of the latter—the French loss being 5225 killed and 3105 prisoners against an English loss of 895 killed and wounded. For this 'conquest' N., who was himself severely wounded in the head, was created Baron N. of the Nile and of Burnham-Thorpe, and received a pension of £2000, a grant of £10,000 from the East India Company, and numerous foreign decorations. At Naples, where he now remained stationed for nearly two years, he was welcomed as the saviour of Italy and raised to the dukedom of Bronte; and here it was that in 1799, under the influence of his unhappy attachment for Lady Hamilton, he committed the one act that sullies his public reputation—the judicial murder of Prince Francesco Caraccioli, an old man of seventy, whose offences, if any, were solely against the Neapolitan government. N. returned with the Hamiltons through Germany to England (1800), and on January 13, 1801, he separated from Lady N., his 'adopted' daughter Horatia being born in February. As second in command to Sir Hyde Parker, he sailed for the Baltic (March 12), and in the Battle of Copenhagen (April 2), turning his blind eye to Sir Hyde's signal of recall, and with his own flag of battle nailed to the mast, destroyed the Danish fleet of seventeen vessels, mounting 632 guns, and flanked by two batteries. The English loss was 953 killed; that of the Danes, in killed and wounded, 6000. Created a viscount, N. failed in an attack on the Boulogne flotilla (August 4), after the Peace of Amiens spent a year with the Hamiltons at Merton in Surrey, and was present at the death of Sir William, April 6, 1803. On the renewal of the war he was appointed to

the command of the Mediterranean fleet, and only quitted his ship the *Victory* for three hours from May 1803 to August 1805—a period spent in the blockade of the French fleet in Toulon and in chasing it to the West Indies and back. On October 21, 1805, he at last fell in with the united fleets of France and Spain off Cape Trafalgar. The enemy's force was forty vessels of 2964 guns, the English thirty-one of 2322 guns. At 11.40 A.M. N. hoisted the signal, 'England expects every man to do his duty'; at 1.15 he was struck by a bullet from the mizen-top of the *Redoubtable*; and at 4.30—when the victory was already decided, twenty of the enemy's vessels having struck—he died, with his last breath commending Lady Hamilton and his child to the nation. He was buried January 9, 1806, in the crypt of St. Paul's, where Northesk and Collingwood, his Trafalgar captains, and the Duke of Wellington were afterwards laid. His brother was made an earl, with a pension of £6000; £10,000 was voted to each of his sisters; and £100,000 for the purchase of an estate. Lady Emma Hamilton, who, born in Cheshire in 1761, had been successively a servant, a courtesan, a model to the painter Romney, and since 1791 the wife of Sir William Hamilton (q. v.), died in extreme poverty at Calais, January 15, 1815. Puny and sickly in body, suffering from sea-sickness to the last, and troubled by a settled melancholy, N. had yet throughout been animated by the conviction that he would some day have a gazette of his own. He 'hated a Frenchman,' but he was ever merciful to the conquered, and his grandest monument is the concurrent admiration expressed for him by the historians of the nations he subdued. His own men, the very mutineers of the *Nore*, worshipped him for his chivalry and kindness; enemies he had none, at least of his own making; and jealousy he could only feel for another, never towards him. He was 'a sinner, but not a great one,' and could honestly thank God that he had done his duty. See the Lives of N. by Clarke (1809), Churchill (1813), Southey (1814), Tucker (1847), Pettigrew (1849), and Allen (1853); in French by De Forges (1860), and Lamartine (1863). Sir Harris Nicolas edited N.'s *Despatches and Letters* (7 vols. Lond. 1844).

Nelum'bo, or **Nelum'bium**, a genus of aquatics, forming a sub-order of *Nymphaeacea*. From a fleshy root-stock stems arise, bearing large pellate leaves that float upon or rise above the surface of the water, and flower-stalks of equal height ascend, bearing solitary flowers remarkable for their size and beauty. The receptacle ('fruit') is shaped like a funnel, in the upper surface of which the numerous ovaries ('seeds') are placed each in a socket. *N. speciosum*—the Pythagorean bean—has a wide distribution in Asia, occurring also in Egypt and in Australia. The starchy root-stock and the seed are both used as articles of food. The latter is in size and shape like an acorn, with a delicate almond-like flavour. The plant is held sacred by the Hindus, who prepare a wick from the spiral vessels of the leaf-stalks to burn in their pagodas. In China, Japan, and Thibet it is also used in religious ceremonies, and it was worshipped by the ancient Egyptians. The large rosy or white flowers are very fragrant, and the leaves being covered with a felt of microscopic hairs, have the property of repelling water, which runs off them like quicksilver. *N. luteum*, a native of Jamaica and N. America, is a handsome plant with leaves one or two feet in diameter, and yellow flowers that measure about a foot across. The capsular fruit contains from 20 to 40 seeds, having a pleasant taste. The fleshy root-stock tastes like the sweet potato.

Nematel'mia (from the Gr. *nēma*, a 'thread,' and *helmins*, a 'worm'), a group of animals including many parasitic forms, but also some beings which are of non-parasitic habits. It is included in the class *Scolecida* (q. v.), to which the tape-worms, flukes, and other true parasites belong. The body is rounded—the term N. being used in contradistinction to the word *Platyelmia*, which designates the tape-worms, and other flat-bodied organisms. In many N. the skin shows traces of segmentation, such as is seen in the true worms, but their internal structure is wholly different. Most N. are *dioecious*, that is, have the sexes in different individuals. The nervous system appears to consist of an anterior nerve-mass or masses, from which nerves are distributed to the posterior and lateral portions of the body. The N. have the system of vessels known as the *water-vascular* system. Three orders of N. are reckoned:—(1) the *Acanthocephala* or 'thorn-headed worms,' which live as parasites in the digestive systems of birds and fishes; (2) the *Nematoda*,

which include the most typical N.; (3) the *Gordiacea* or 'hair-worms' (*Gordius*, &c.) which are found as parasites within the bodies of insects.

Nematocyst, a term frequently applied to the *Cnida* or thread-cells found in the tissues chiefly of *Coelenterate* (q. v.) animals. Each N. consists of a sac filled with fluid, and having coiled up in its interior a thread or spiral filament. On being irritated in any way, the sac ruptures, the 'thread' is everted, and the fluid at the same time escapes. If the thread and fluid be brought into contact with the tissues of some animals, a sharp, stinging sensation is produced. By means of the N., *Coelenterate* animals kill or paralyse their prey, while some (e.g., Jelly-fishes, &c.) are able to inflict severe injury even on man himself.

Nematoda, a division of *Nematelmia* (q. v.) including the round and thread-worms (*Ascaris* and *Oxyuris*), which infest the human alimentary canal, the vinegar eels (*Anguilla*), the *Trichina* (q. v.), the Guinea Worm (q. v.), and other parasitic forms. The N. have long cylindrical bodies, and a distinct mouth and digestive system, while the *anus* or vent is found at the posterior extremity of the body. The system of water-vessels (*water-vascular system*) is in many instances contractile, and opens on the exterior of the body by lateral or ventral pores. The sexes are in distinct and separate individuals; and it is a remarkable fact that male N. are, as a rule, but rarely met with, the females, on the contrary, being plentiful. For example, the male Guinea worm has not been discovered—a result probably due to its presumably minute size, or to its existing in some unsuspected form. The N. have no lateral appendages, although sometimes spines or papillæ are found. The skin is provided with a dense, horny layer; and there is a total absence of *cilia* at every period of life. Layers of muscles are seen on investigation of the body-substance, and the nervous system consists of a ring of nerve fibres and cells surrounding the gullet, and distributing filaments throughout the body. The generative aperture in the male N. occurs at the hinder extremity; in the female, at the centre of the body. N. have been divided into (1) *Polymyaria*, or those in which the muscles of the body are divisible into many series of muscle-cells; (2) *Meromyaria*, or those in which eight longitudinal series of muscle-cells exist; and (3) *Holomyaria*, in which the muscles are not divisible into such series.

Nemea, a deep and fertile vale of Argolis, between Cleonæ and Phlius. Here was a splendid temple of Zeus, situated in a sacred grove; and here too, twice in every Olympiad, or generally speaking once in every two years, the Nemean games were celebrated. These games were instituted, according to some, by the Seven against Thebes, to commemorate the death of Opheltes, afterwards called Archemorus. This form of the legend is well known to readers of Greek poetry (see Pindar, *Nem.* iii. 114, &c., and Strabo, viii. 377). Other legends ascribe the institution of the Nemean games to the Greek Hercules after he had slain the Nemean lion. The games and competitions were such as generally belonged to the Gymnasium (q. v.). The judges in the Nemean games were dressed in black robes. The period of their celebration is uncertain. In addition to the above cited authorities, see Livy xxvii. 30, &c., xxxiv. 41, Polybius x. 26, and Villoison's *Histoire de l'Acad. des Inscript. et Bell. Lett.* vol. xxxviii. p. 29, et seq.

Nemertes and **Nemer'tida**, names given in Zoology, the former to a genus *Scolecida* (q. v.), or forms allied to the Tapeworms, *Nematoda* (q. v.), &c., the latter to the division in which N. and its companion genera are contained. The *Nemer'tida* form a group included with the tapeworms, flukes, and allied organisms in the division *Platyelminia*, or that of the 'flat-bodied' *Scolecida*. They are distinguished by having long worm-like bodies, a distinct *anus* or vent, and a perivisceral or body-cavity, by the *water-vascular system* being closed in the adult, and by the sexes, with few exceptions, being distinct. These animals have a system corresponding to the blood system of other animals, in addition to the *water-vascular system*. The genus *Nemertes* is represented by marine organisms, which exist as worm-like bodies, occasionally attaining a length of from 30 to 40 feet. Their bodies, which are found among the seaweed, &c., on the sea-shore, are susceptible of sudden contraction to a mere fragment of the size above mentioned. The N. and its neighbours pass through peculiar phases of

development. The young N. comes from the egg as a helmet-shaped body, which Johannes Müller captured in the towing-net, and to which he gave the name of *Pilidium*. After living an independent existence for a longer or shorter period, this *Pilidium-larva* exhibits a growth of new matter on one side of its alimentary canal. This new growth eventually appears as a worm-like body, and is, in fact, the future N., which ultimately detaches itself from the larval body.

Nem'esis, daughter of *Nox*, *Erebus*, or *Oceanus*, is a personification of the moral reverence of law, or the natural fear (*metus*) of committing a guilty action as against the bodily fear (*timor*) and the everlasting dread that weighs upon the mind of the sinner (*formido*). In later writers N. is the power of destiny; in Hesiod and Pindar she is a fatal divinity as well. She is, moreover, constantly allied with *Aiê* and the *Eumenides*. In a word, N. is a power checking the extravagance of fortune—the avenging Fate—the *Dikê* that sooner or later overtakes the reckless.

Nen'agh (Ir. Gael. *n'Enach*, 'the place of assembly'), a town in Tipperary county, Ireland, on the Roscrea and Limerick Railway, 28 miles N.E. of Limerick. It has an ancient keep called N. Round, a fine parish church, erected in 1861, a court-house, barracks, &c., and carries on some trade in woollens, tobacco, and candles. Three newspapers are published here. Pop. (1871) 5531.

Nenn'ius, the alleged author of a *Historia Britonum* which possesses some historical value. In its first form this work probably belongs to the close of the 7th or the beginning of the 8th c. The author is unknown, but his compilation soon became very popular, and various additions were made to it from time to time. The first of these additions was the *Genealogia*, a pedigree of the kings of the different English states reaching to the year 738, and thus perhaps indicating the date of its composition. The lives of St. Germanus and St. Patrick are still later insertions. The name N. is first attached to an 'edition' of the work coming down to 858. The three oldest MSS. belong to the 10th c. The Vatican MS. bears the name of Mark the Anchorite, and contains the date 946. The Paris MS. corresponds with it in all essentials, but the British Museum MS. has additions not found in any other, and which could not have been made earlier than 977. The later MSS. are twenty-five in number. Skene reckons six different forms of the work prior to the 12th c. The *Historia* was first published by Eale (1691), whose text was reprinted by Bertram at Copenhagen in 1757. More recently it has been edited by the Rev. Mr. Gunn (1819), and J. Stevenson (1838). See Skene's *Four Ancient Books of Wales* (vol. i. pp. 37-41).

Ne'ophyte (Gr. *lit.* 'one new-planted,' i. Tim. iii. 6, A.V. 'a novice'), in the early Christian Church, meant one newly converted or one newly baptized, when baptism followed immediately on conversion. Afterwards, when converts were put through a long course of instruction and probation before baptism, N. or novice, like *Catechumen* (q. v.), was a name given to those thus preparing for baptism.

Neoplat'onism is the name given to a school of philosophy at Alexandria which attempted to reconcile a positive religious faith with the sceptical conclusions of the New Academy. It was founded on Philo's doctrine of the *logos endiathetos* or Divine idea and the *logos prophorikos* or Divine idea realised, which again was really an attempt on Platonic principles to escape from the admitted inconceivability of the Unconditioned or God. The leading names of the first period of N. are Ammonius Saccas, a street porter, and the mystic Plotinus, who lectured at Rome. Origen and Longinus were also disciples. The second period is directed by Porphyry and Iamblichus, who gave logical system to the metaphysical constructions of Plotinus. They come into intellectual conflict with Christianity, especially when the Christian Emperor Constantine was succeeded by the Neoplatonist Julian the Apostate. The third period is identified with the name of Proclus, the most genuinely scientific spirit of them all. It did not survive the reign of Justinian. The Neoplatonists considered the Platonic Dialectic of Universals to give insufficient ground of belief, and therefore introduced the Ecstasy (q. v.) or identification of subject and object in the art of knowledge. By this was elaborated the famous Alexandrian Trinity, in which Unity proceeds to its second and third Hypostases

(q. v.) of Mind (*nous*) and Universal Soul (*psyche*). This Unity (*τὸ ἐν ἀπλόῳ*) is not numerical, nor is it the Unconditioned *per se*; it is the Ideal Beauty, the Supreme Good, or in Hegelian language, the Immanent Negative, the Absolute Nothing. The system also resembles the *substantia* of Spinoza, with its two attributes of thought and extension. By the doctrine of Emanation (q. v.) the Neoplatonists further preserved their Pantheism and escaped from the various forms of Dualism previously accepted, as in Jupiter organising Chaos; the Demiurgos of Plato, who directs matter and motion; the Immovable Thought of Aristotle, and the personal Creator of the Christian world. The great feature of N. is the combination of an extremely subtle and powerful metaphysic with a mysticism which in some cases became almost ascetic. It was this oriental religious spirit which opposed it to Christianity. Besides the ordinary handbooks of History of Philosophy, see Matter, *Essai Historique sur l'École d'Alexandrie* (2 vols. Par. 1820), Simon, *Histoire de l'École d'Alexandrie* (2 vols. Par. 1843), and St. Hilaire, *De l'École d'Alexandrie* (Par. 1845).

Neozoic (Gr. 'new life' formation), in Geology, is a term invented by Edward Forbes to include all the Mesozoic or Secondary and Kainozoic or Tertiary formations. It thus stands in contradistinction to Palæozoic, but though geological evidence renders its adoption plausible, it is rarely used in standard text-books.

Ne'pa. See WATER SCORPION.

Nepaul' (*Naiṇḍl*, from its legendary founder Naimuni), an independent state, among the Himalaya mountains in the N. of India, closely connected by treaty with the British power. The inhabited part consists of the valleys of the Gogra, Gunduk, Kovi, and other tributaries of the Ganges, together with the *terai* or marshy strip that everywhere intervenes between the Himalaya and the plain of Hindustan: in the higher tracts the snow often lies for ten months out of the twelve. For fertility, the valley of Khatmandu has been compared with Cashmere. The entire length, from S.E. to N.W., is about 500 miles; the breadth varies from 70 to 100 miles; the area is estimated at about 54,000 sq. miles; the pop. at 2,000,000; the total revenue may amount to £1,000,000; the army consists of 13,932 foot, 117 horse, 420 guns and 2282 artillerymen. The guns, which are borne by men, are mostly smooth-bored; like the muzzle-loading rifles of the infantry, they are made in Nepaul, but some difficulty is found in the manufacture of cartridges. The most formidable weapon is the kookrie or Gurkha knife. The currency consists of silver *mohurs* and various kinds of copper *pice*, which are in common use within British territory. During the four years ending 1876 the state mints are ascertained to have struck coin valued at £200,000; but British rupees are in great demand. The dominant race is the Gurkhal, of a mixed Hindustani origin, who are to be distinguished from the Gurkhas or hill men proper: both of these are Hindus in religion, but there are also many subject tribes who are Buddhists. The name of the present ruler is Surender Bekrum, and his title is Mahārāj Dheraj; but for the last thirty years all power has been in the hands of the celebrated Prime Minister, Sir Jung Behaudur (see JUNG) who died in February 1877, and of his brother, who has succeeded him in office. The staple produce is rice, other cereals, and oilseeds; the surplus is exported into the plains, in exchange for Manchester piece-goods and salt. The manufactures are a coarse cotton cloth, and metal wares of all sorts. The chief trade route is through the Behar district of Champarun. The Bengal registration returns for 1876-77 show a total export from N. valued at £632,000, including cattle (£143,000), food grains (£120,000), oil-seeds (£100,000); the imports were valued at £482,000, chiefly European piece-goods (£141,000), native cotton goods (£38,000), salt (£39,000), brass and copper ware (£21,000). These figures only refer to a portion of the trade. The N. government levies an elaborate system of duties along the frontier, but these are not primarily intended to have a protective effect. The principal towns are Khatmandu, Bhatgaon, Lalita Patun, Jumla, and Gurkha. The history of N. is referred back to a remote and legendary past. The present dynasty, which claims a Rajput descent, first established itself in 1769. For 200 years previous they had ruled in the town of Gurkha, but they then conquered the whole of N. In 1792, they came into collision with the Chinese, but were compelled to submit to an ignominious peace. The first relations with the British date from the same period. Aggressions

in the direction of Gurhwal led to the Gurkha wars of 1814-15, in which the Nepalese fought bravely and were with difficulty defeated by Sir D. Ochterlony. The peace of Segowlie, ratified in 1816, still governs our relations with N. The Nepalese allowed a British Resident at Khatmandu, acknowledged the British as paramount, and agreed not to employ any Europeans. The Resident, with an escort of 95 natives, is still the only Englishman in the State; but since the accession to power of Sir Jung Behaudur, our relations with N. have been of a most friendly character, and a salute is annually fired on the Queen's birthday. N. also maintains its ancient connection with China, and receives, or did till recently receive, a tribute from Thibet. In 1857 Sir Jung Behaudur led in person 16,000 men to assist the British in stamping out the Mutiny. His services were especially valuable in the final capture of Lucknow and the pacification of Oude. In recompense, a large strip of the Oude *terai* was ceded to N., and the Gurkha soldiers received the Mutiny medal. See Brian Hodgson's *Essays* (1874), Burnouf's *Introduction à l'Histoire du Bouddhisme* (Par. 1847), and Wright's *History of Nepal* (Camb. 1877).

Nepen'thes is the sole genus of the natural order *Nepenthaceæ*, consisting of about twenty species, mostly natives of the islands of the Indian Archipelago, and all plants of much interest from the curious pitcher-like appendages that terminate their leaves. The one best known in cultivation is *N. distillatoria*, commonly called the Pitcher-plant. It belongs to Ceylon. But the finest species yet described is from Borneo, and named after Rajah Brooke *N. Rajah*. In it the excurrent midrib or tendril from the apex of the leaf is twenty inches long, as thick as the finger, and terminates in a pitcher that will contain nearly a quart of water. The fluid secreted by the plant is attractive to insects, the destruction of which it effects by drowning, and it is supposed that the products of their decomposition are beneficial to the plant by absorbing the nitrogenous substances, and digesting the same within its tissues.

Neph'rite (Greek *nephros*, 'kidney,' so called on account of a supposed influence this mineral, in common with other green stones, possessed on diseases of the kidneys), is a species of Jade (q. v.). Chemically, it consists of an anhydrous silicate of lime and magnesia, and it forms a very tough, hard, translucent mineral, with a colour varying from a dark green to an almost milky white. It is very highly esteemed by the Chinese and Japanese for ornamental purposes, by whom it is carved in the most elaborate manner. The supplies of N. in oriental countries are chiefly obtained from Eastern Turkestan, where famous quarries have long been known; but recently it has also been found extensively in Eastern Siberia. The mineral is also found in New Zealand, where it was formerly much used by the Maoris for making charms or household gods, and for war clubs, whence it is known as *axestone*.

Nephrit'is (Gr. *nephros*, 'kidney'), is the term used to indicate inflammation of the kidneys. Active congestion of the kidneys terminating in N. may be the result of exposure to cold; or of the irritation of such medicines as cantharides or turpentine; or of the various febrile and inflammatory diseases. Passive congestion may be caused by interference with the general venous circulation from cardiac or pulmonary diseases, the gravid uterus, or tumours pressing on the renal veins or inferior vena cava alone. N. may be also caused by the direct irritation of a renal calculus or embolus, or by inflammation of the bladder passing along the ureter causing *pyelitis*, or inflammation of the lining membrane of the kidney, which may implicate the substance of the kidney and terminate in *suppurative N.* The pus formed may escape by the ureter, or an abscess may form, enlarging and burrowing in all directions towards the diaphragm, the loins, the peritoneum, or descending along the psoas muscle and pointing under Poupart's ligament. The symptoms of N. are general febrile symptoms; pain and tenderness in the loins, increased by pressure; irritability of the bladder, and the presence of blood, mucus, or albumen in the urine. In suppurative N. these symptoms are aggravated, with rigors and hectic fever, suppression of urine, and death from exhaustion. Treatment.—In active congestion of independent origin, it is advisable to leech or cup the loins, and apply hot fomentations. The treatment of *pyelitis* and of suppurative N. depends very much on ascertaining the cause, and employing agents to remove irritation and support the strength. See KIDNEYS, DISEASES OF.

Nepomuk. See JOHN OF NEPOMUK.

Nepos, Cornelius, a Roman historian, lived between 660 and 730 A.U.C. (94 B.C. and 24 B.C. Teuffel; 80 B.C. and 28 B.C. Koch). Though the precise period is unascertained, we yet know that N.'s lifetime lies between the extreme dates given above, inasmuch as he was the friend of Cicero, Atticus, and Catullus. He was certainly a native of Verona, or of some place in its vicinity. To N., Catullus—the young gentleman of Verona—dedicated his *Lepidum Novum Libellum*, in which dedication the *Chronica*, a universal history in three books, is referred to in terms of unqualified praise. The other works of N. are *Exemplorum Libri*—a collection of remarkable sayings and doings; *De Viris Illustribus*, perhaps the same work as the preceding under a new title; *Vita Ciceronis*; *Epistole ad Ciceronem*; *De Historicis*; and if we are to credit the younger Pliny, *Poemata* (vide Pl. Ep. v. iii.). None of these survive except the *De Viris Illustribus*, which till the middle of the 16th c. was published with the bastard title, *Emilii Probi de Vita Excellentium*. In 1569, however, Dionysius Lambertus showed that the so-called work of Probus was in all probability the long-forgotten work of N. (many critics, however, regard it as merely an abbreviation of N.'s work). Among later editions of N. are those of Schott (fol. Frankf. 1608); Van Staveren (8vo, Leyd. 1734, 1755, 1773 revised by Bardilli, 1820); Paufler (Leips. 1804); Tzochucke (8vo, Gott. 1804); Breml (8vo, Zurich, 1820); and that by Lemaire (8vo, Par. 1820). The most recent editions are those by Nipperdey (5th ed. Berl. 1868); Koch (Leips. 1855); C. W. Nauck (Königb. 1856); Siebelis (6th ed. 1868) Halm (Leips. 1871).

Nep'tune (probably from Gr. *naïō*, Lat. *nato*, 'to swim,' and a contraction for *Navitunus*), the chief marine deity of the Romans, was a brother of Jupiter and Pluto. He was identified both as to powers and attributes with the Greek Poseidon (q. v.).

Neptune is the most distant of all known planets from the sun, round which it revolves at a mean distance of 2750 millions of miles, in an ellipse of eccentricity .00872. Its orbit is inclined $1^{\circ} 47'$ to the ecliptic. The diameter of N. is estimated at 37,000 miles, but the immense distance of the planet forbids us placing any confident reliance upon such determination, and prevents us altogether from assigning a period of axial rotation. Its volume is 108 times, but its density is only 16 times that of the earth. One satellite has been observed and its elements determined, giving an inclination to the ecliptic of no less than 29° . Its motion is believed to be retrograde, but this is not satisfactorily established. The year of N. is equal to 60126.72 of our days, or nearly 165 of our years. To the naked eye N. is quite invisible, though it ranks next in point of absolute size to Jupiter and Saturn. The peculiar interest attached to this planet is the history of its discovery. In 1820, Bouvard began elaborate calculations of the elements of the motion of Uranus; but his results, which took account in theory only of the actions of the sun, Jupiter, and Saturn, deviated widely from observation. Ultimately he was led to express his belief that there must be an external planet disturbing the motions of Uranus. In 1841, J. C. Adams of Cambridge began, from the known elements and observed perturbations of Uranus, to calculate the position of the hypothetical planet, and in July 1846, sent to the Cambridge observatory his results, which lay for some time, however, unheeded. Leverrier, the French astronomer, had been engaged in the same investigation; and though somewhat later in beginning his calculations, and less full in final details than his English contemporary, he published his results on August 31, assigning a position to the unseen planet closely concordant with that assigned by Adams. From his results, the Berlin astronomers detected the planet on September 23, 1846. Both calculators, in deducing their results, gave to N. a mean distance, as indicated by Bode's Law (q. v.)—a supposition which is now known to be far from true. It was therefore a wonderful chance that at the time of discovery their hypothetical planet of 242 years' period should have coincided with the true planet of 165 years' period—a coincidence which happens only once every 500 years. Still the result is a remarkable link in the chain of evidence which warrants us in accepting Newton's law of gravitation as a law of nature.

Neptune's Cup (*Thalassema Neptuni*), a species of sponges found in tropical seas, and forming one of the largest examples

of this group of animals. Occasionally specimens may be met with from 4 to 5 feet in height. The fibrous substance is very tough when dried, and preserved in museums the exterior looks like the bark of a tree.

Nerbudda (*Narmada*), a large river of India, which flows nearly due E. and W. across the centre of the peninsula, and is sometimes regarded as separating Hindustan proper from the Deccan. It rises in the native state of Rewa, and after a total course of 801 miles, chiefly through the Central Provinces, falls into the Bay of Cambay by a fine estuary, 30 miles below the town of Broach. Its drainage basin is 36,400 sq. miles. Its tributaries, which are neither important nor numerous, come chiefly from the N. The greater part of its valley is shut in between the Vindhya and Satpura mountains, and it preserves throughout the characteristic of a hill stream. Being much broken by gorges, rapids, and waterfalls, it is of little use for navigation or for artificial irrigation. Large ships, however, can ascend the estuary to Broach. The N. valley is famous for its fertility and mineral wealth. It is composed of the black soil which yields inexhaustible crops of wheat and cotton; and these, together with its beds of coal and iron, are now utilised by means of the railway, which runs up the valley from Khunda to Jubbulpore, nearly 300 miles. In traditional sanctity the N. is second only to the Ganges, and its banks are crowded with historical sites and temples. The regular pilgrimage on foot from its source to its mouth and back again is estimated to occupy two years.

Nereids, the fifty daughters of Nereus and Doris, chief of whom was Thetis, mother of Achilles. They dwelt in the Ægean Sea, in shell-decked and vine-shaded caves on the seaboard, or in the sea-depths along with their sea-born parents. The N. were the attendants of the great sea-gods, especially of Poseidon (q. v.), whose power over the sea was supreme. Sailors paid honour to them. Milk, oil, honey, and goats' flesh were the gifts invariably offered. In works of art Nereus and his daughters appear crowned with sea-weed over eye, chin, and breast. See *Ilist, Mythol. Bilderb.* (p. 150, tabb. 18, 19).

Nereis, a well-known genus of *Annelida* or worms belonging to the order *Errantia*, the species of which inhabit the sea coasts. From the large number and prominent nature of the bristles or *setæ* which fringe the sides of N. and its companion-genera, the order has sometimes received the name of *Polychæta*. The animals are *diœious*, and each joint of the body has four processes named *parapodia*, which bear the bristles or *setæ*. The head is distinctly marked, and bears eyes, tentacles, and a protrusible proboscis provided with jaws. The eyes and sense organs are borne on a segment above the mouth and named the *prostomium*. The nervous system is distinct, and consists of large *cephalic* or head-ganglia or nerve masses, and of a ventral chain of ganglia. The breathing organs are plumate gills borne on the dorsal or back portions of the body-segments. The embryos are ciliated and free-swimming. The species of N. are often named 'sea-centipedes,' from the prominent character of the side-bristles, which, however, are not in any sense legs.

Nereites, the name given to certain markings found in some of the oldest fossiliferous rocks (e.g., Cambrian formations), and which are supposed to represent the petrified tracks of worms, such as are well seen in a fresh condition on modern sea-beaches. Many of these tracks are, however, of doubtful nature. Some were described in former years as the actual fossilised bodies of the worms themselves.

Nereus, in the Greek myth, was the son of Pontus and Gæa, and the husband of Doris, by whom he became the father of the fifty Nereids. Under Poseidon he ruled the Mediterranean. His daughters, whose names are variously given by Homer (*Il.* xviii. 39), Hesiod (*Theog.* 240), and Pindar (*Isthm.* vi. 8), were distinguished, on the one hand, from the Oceanides, the dwellers in ocean, and on the other from the Naiades, the nymphs of streams and lakes. See NEREIDS.

Neri, St. Filippo di, founder of the Congregation of the Oratory (q. v.), was born at Florence, 23d July 1515, of a noble family. In 1533 he went to Rome, where, after completing his studies and becoming a priest (1551), he devoted himself to works of charity, and gained a high reputation for piety and zeal. N. stimulated greatly the revival of religious earnestness within the Catholic Church after the Reformation. His good-humour and

ready wit made him a universal favourite, and in Rome to this day the 'Good Filippo' is peculiarly the 'layman's saint.' He died May 26, 1595, and was canonised by Gregory XV. in 1622. See *Faber's Spirit and Genius of St. Philip Neri* (1850).

Ne'rium. See OLEANDER.

Ne'ro, Roman Emperor A.D. 54-68, was the son of Cn. Domitius Ahenobarbus and of Agrippina, daughter of Germanicus and sister of Caligula. The term N. was a cognomen of the Claudian gens, and signified in the Sabine tongue 'brave and vigorous.' N.'s original name was L. Domitius Ahenobarbus; but after his mother's marriage with the Emperor Claudius, her uncle, he was adopted by Claudius (50 A.D.), and his name was exchanged for that of N. Claudius Cæsar Drusus Germanicus. N. was born at Antium, 15th December 37 A.D. Shortly after his adoption by Claudius, N. at the age of 16 married Octavia, daughter of Claudius and Messalina. Seneca had been one of his early instructors, and under his tuition N. had given evidence of a taste for the arts; but he was naturally weak and wayward. On the death of Claudius (54 A.D.), at the announcement of Burrhus he was declared Emperor instead of Claudius' own son, Britannicus, the rightful heir. His elevation, instigated by the prætorian guards, was at once sanctioned by the Senate and by the provinces. N. began his reign with promise, but the baneful influence of his mother led him rapidly into a life of folly and crime. He caused Britannicus to be basely poisoned because he feared him as a rival; secured his mother's assassination to please his mistress Poppæa Sabina (wife of Otho, afterwards emperor), to marry whom he divorced his own wife Octavia on the ground of barrenness, and shortly thereafter had her murdered. The Nemesis that pursues the villain did not fail to overtake N. His murdered mother's ghost haunted him to the hour of his death. Stung with remorse he strove to drown memory in fresh riot, and condescended to the undignified callings of charioteer, musician, and actor. Meanwhile dangers gathered both in the East and West. In 60 A.D. a comet appeared portending, it was believed, some great disaster. In 61 A.D. occurred the insurrection in Britain under Queen Boadicea, soon quelled, however, by the vigorous action of Suetonius Paulinus. The year A.D. 62 witnessed the death of Burrhus, the retirement of Seneca, and the Parthian war in Armenia. In the following year the city of Pompeii was almost wholly destroyed by an earthquake; while at Antium, to N.'s unbounded joy, Poppæa gave birth to a daughter, who however survived only a few months. In 64 A.D. occurred the great conflagration at Rome—a disaster due, according to Dion and Suetonius, to N. himself. N., on the other hand, threw the blame on the Christians, whom he persecuted with relentless fury. His next step was to rebuild the city in more than its former magnificence, and to rear for himself a gorgeous palace, called from its golden ornaments *Aurea Domus*. To gratify the people he gave splendid shows and made princely distributions of corn. In 65 A.D. a plot was formed against him, but it was discovered and divulged by Milichus, a freedman of one of the conspirators. Among the many whose death followed in consequence may be mentioned Seneca and Lucan. Poppæa's death, caused by a kick from her brutal husband during her pregnancy, came next. N. then proposed to Antonia, the daughter of Claudius, but she declined his suit, and on that account suffered death. He now married Statilia Messalina, whose husband he caused to be slain. In 67 A.D. he attended the Olympic games. In 68 A.D. the Gallic and Spanish legions rose against him. This was followed by the defection of the prætorian guards, whereupon N. fled from Rome to the house of a freedman Phaon, about four miles off, and there committed suicide, 11th June 68 A.D. N.'s brief life is a long catalogue of hypocrisies and crimes; and one loathes to think that such a monster of vice should have been the votary and patron of poetry, music, and sculpture.

Nertchinsk', a town of E. Siberia, in the province of Transbaikalia, on the left bank of the Nertcha, near its confluence with the Shilka, 466 miles E.N.E. of Kiachta. Founded in 1652 by the Cossack chief Belekof, N. has an observatory and school of mines, and is the centre of an extensive mining district inhabited by Russian exiles, and producing silver, lead, tin, iron, copper, gold, and coal. Pop. 4000.

Ner'va, M. Coccius, Roman Emperor 96-98 A.D., was either a native of Narnia, in Umbria, or born of Narnian parents. The

date of his birth was 32 A.D. He was consul with Vespasian 71 A.D., and with Domitian 90 A.D. On the assassination of the latter he was declared emperor. His mildness, justice, and prudence were beyond question; but he had not the vigour and firmness to control the turbulence of an insolent soldiery. His nobleness of purpose, and his good sense were, however, evinced by his choice of Trajan—then at the head of the forces in Germany—as his successor. N. conferred on him the titles of Cæsar and Germanicus, and tranquillity was again restored. In 98 A.D. N. and Trajan were joint-consuls. N. died 27th January 98 A.D. He was carried to the funeral pyre shoulder-high by the senators, and his remains were deposited in the tomb of Augustus. After his death divine honours were decreed to him.

Ner'vous System is the system of organs in living beings, in virtue of which they maintain relations with their surroundings. Hence the N. S. is said to exercise the function of *Relation*, otherwise known as that of *Innervation* or *Irritability*. The function of *Nutrition* (q. v.) in living beings may be said to bring the organism into relation with itself, and to maintain its bodily or physical equilibrium. The function of *Reproduction* (q. v.) brings the individual being into relation with its species or race, while the function of *Relation* or that of the N. S. unites the other functions by governing and controlling them, and brings the organism into appreciative contact with its environments and with the world in which it lives. In a general survey of the structure and functions of the N. S. we shall firstly indicate what are its essential characters; secondly, what are its various forms in animals; thirdly, what are the details of innervation in the lowest animals and plants; and, fourthly, what is the structure and physiology of the various parts of the N. S. of man.

The *essential characters* of a N. S. in any animal may be said to comprehend three parts or sets of organs working together in harmonious adjustment. These parts are (1) a *nerve-centre* or organ for the origination or reception of nervous impressions; (2) a *nervous cord* or *nerve* for the transmission of these impressions; and (3) an *organ* or *part* in which the nerve ends, or from which impressions are conveyed, and which is connected by the nerve with the nerve-centre. In the simplest nervous acts of man—illustrating the phenomenon known collectively under the name of *reflex action*—the relationship of these three parts is well shown. Reflex action, or the simplest nervous acts may take place without *consciousness*. As an illustration of reflex action, let us try to determine the *rationale* of the simple action of the closure of the eyelids with the object of protecting the eye. On a blow being aimed at the face the eyelids close instantaneously, and the action may be said to be essentially automatic. But it is evident that notwithstanding the apparent simplicity of the act there are involved in its performance a set of complex conditions. There has been firstly transferred to the brain or nerve-centre, and to that part of the brain regulating the movements of the eyelids, an impression of danger from without, which, because it proceeds to the nerve-centre, may be termed *centripetal*. This impression in the next place was rapidly transformed in the brain into another impression of an exactly opposite kind, and which proceeded outwards, or *centrifugally* through the nerves, to the eyelids, causing their contraction. Thus the first impression received from without has been *reflected*, as it were, to the organ concerned, whence the phenomenon is known as *reflex action*. Similarly, when any substance is taken into the mouth, a flow of *Saliva* (q. v.) is caused by reflex action. The contact of the substance with the nerves of the mouth produces an impression which travels to a nerve-centre, whence the impulse is 'reflected' along the nerves of the salivary glands with the result of stimulating these organs, and of causing a flow of saliva. Nervous impulses, however, do not always originate from outward impressions. When an idea, or, as we term it, a 'thought,' is conceived or generated in the brain, as the beginning of any simple act, such as that of touching any substance, the impression first proceeds from the brain along the nerves disturbed to the muscles of the fingers. The muscles are thereby stimulated to action and the fingers are brought in contact with the object desired. But this forms only one half of the action. How, it may be asked, do we know that we have touched the object in question? If we suppose that the sense of touch is the only sense concerned in the process, as in the case of a blind person who could not 'see' that he had touched the object, we

find that on the fingers being brought in contact with the object, the impression is reflected to the brain or nerve-centre, and we thus become conscious through the sensations evoked that the original behest of the brain has been obeyed. Thus the common acts of life involve a highly complicated nervous procedure; and there is thus illustrated the essential manner in which the N. S. acts—namely, in that of producing impulses which travel outwards and inwards, or *vice versa* (*centrifugally* and *centripetally*), these impulses not only stimulating organs and parts to perform functions, but enabling us also to become aware of the discharge by these organs of their varied functions. It may be remarked, however, that impressions are not invariably reflected to the centres from which they originated, but may proceed to other centres and be diffused to distant parts. In this way originally simple actions become exceedingly complicated, and may occasionally defy analysis altogether. The essential attributes of a N. S. may be summed up in the statement that it originates, conveys, and distributes nervous impressions or impulses which affect the body in fashions as varied as are the directions of the impulses themselves.

Passing now to consider as a second topic the *Comparative Anatomy of the N. S.*, we find the lowest animals or *Protozoa* (q. v.), represented by sponges and many microscopic animalcules, to exhibit no traces whatever of nerves or nerve-centres. This absence of nerves in these lowest organisms is on a par with their rudimentary or negative characters in other respects. Their bodies, consisting for the most part of minute masses of *Protoplasm* (q. v.), exhibit no traces of digestive or circulatory organs. The simplicity and uniformity of their structure, in short, forbid us to expect in them the highest elements of organisation. Among *Cœlenterate* animals (of which the hydræ, sea-anemones, zoophytes, jelly-fish, and corals are examples), a N. S. appears for the first time in the animal world, as we trace the structures of its members from lower to higher grades. In the lower *Cœlenterates*, such as hydræ, the zoophytes, &c., no traces of nerves can be found, and in the sea-anemones, corals, &c., their existence has yet to be proved. But in some jelly-fishes, which are of lower rank than the last-mentioned animals, recent research has revealed the presence of elementary nerve-tracts; and in the *Ctenophora* (q. v.), or highest *Cœlenterates*, represented by *Beriæ*, &c., distinct nerve-elements have long been known to exist. In *Echinozoa* or *Annuloid* animals, represented by sea-urchins (*Echini*), starfishes, holothurians, crinoids, and by many parasitic organisms (e.g., the Tapeworm (q. v.), *Rotifera*, the Fluke (q. v.), &c.), a distinct N. S. is always found. In the sea-urchins and other *Echinodermata* (q. v.) the N. S. exists as a ring of nervous matter, bearing nerve-masses or *ganglia*, from which nerve-filaments are distributed to other parts of the body. In such animals as the Tapeworm, &c., there are two nerve-masses in the anterior region of the body which send filaments backwards; while in the *Rotifera* (q. v.), or 'wheel animalcules,' there is a very large nerve-mass. Among *annulose* or *Articulate* animals, the N. S. is not only invariably present, but is highly developed. These animals are represented by worms, centipedes, insects, spiders, scorpions, mites, crabs, lobsters, barnacles, and other crustaceæ. Their N. S. consists typically of a double chain of ganglia, situated in the floor or ventral region of the body, two ganglia being in each *somite* or segment. This disposition of the nerve-centres occurs in the lower *Annulosa*. But in insects and higher *Annulosa*, the double nerve-chain may and usually does become fused to form an apparently single chain with one ganglion in each *somite* or segment of the body. In *Mollusca* (q. v.), the nervous axis shows two forms or dispositions. In the sea-squirts and other lower molluscs only one nerve-mass or ganglion appears, this being homologous apparently with the supra-oesophageal ganglion of *Annulosa*; but in higher mollusca there are well-marked ganglia. In *Vertebrate* animals, which include the series of 'backboned' forms, ranging from the fishes to quadrupeds, and including man, the great peculiarity of the nervous system consists in its being separated from the other regions of the body, and in its higher specialisation. The brain and spinal cord, together forming the *cerebro-spinal axis* of man, are thus enclosed in a tube formed by the skull and spinal column, and are completely partitioned off from the general cavity of the body. In *Invertebrate* animals no such separation takes place. A second nerve-system, known as the *sympathetic nervous system*, lies

along the front of the vertebrate spine, and is not enclosed within any special tube, but exists in the abdominal and thoracic or general body-cavity of these animals. Regarding the appearance of sense-organs in animals, we find *ocelli* or *pigment-spots*, representing rudimentary eyes, in the jelly-fishes, in *Cœlenterates*, and *Echinozoa*. In the former, *auditory vesicles* or rudimentary organs of hearing are also found. In *Annulosa* both simple and compound eyes are found, as well as auditory organs, and *antennæ* or feelers exercising the sense of touch, and presumably that of taste as well. Molluscs have usually eyes and auditory sacs, and in *Vertebrate* animals the five senses are represented in a more or less perfect degree.

The consideration of the *general anatomy and physiology* of the human N. S. forms a fourth department of our present inquiry. In the N. S. of man, as well as in the simplest N. S. which can be examined, there would appear to be two distinct elements discernible by the microscope. These elements are: 1, *nerve-fibres*; and, 2, *cellular* or *vesicular* nerve-elements. The first form the nerves themselves; the last occur in the nerve-centres either solely or mingled with the fibrous structures. The function of the fibres appears to be that of transmitting and conducting the nervous impulses, while that of the nerve-cells and vesicular elements is probably concerned with the production of the nervous force itself. In man two great systems of nerves are found. The *cerebro-spinal* N. S. already mentioned is contained within the skull and vertebral column, and consists of the brain and spinal cord. The second system, known as the *sympathetic system*, is situated within the visceral tube or region, and consists of a series of *ganglia* or nerve masses lying along the front of the spine, and having connection with the *cerebro-spinal axis*. From each of these systems or centres nerves originate.

The *nerve-fibres* of which nerves are composed are in reality minute *tubules*, forming disconnected or frequently interlacing bundles. The bundles are connected by tissue in which the

NERVE-FIBRES.—a, Medullated fibre in the fresh state; b, similar fibre showing the nuclei of the limiting membrane; c, axis-cylinder projecting beyond the torn limiting membrane of a fibre, from which the medullary sheath has been partially removed; d, substance of medullary sheath escaping in irregular drops; e, fibre treated with acetic acid; f, fine medullated fibre from brain, the medullary sheath running into drops, being unsupported by any limiting membrane; g, grey fibres.

blood-vessels of the nerves are contained. The nerve itself is covered by a delicate sheath of fibrous tissue named the *neurilemma*. Nerve-fibres are of two kinds—the *white, medullated*, or *dark bordered* fibres found in the nerves belonging to the *cerebro-spinal* system; and the *pale, non-medullated*, or *gelatinous* nerve-fibres found in connection with the *sympathetic* system. When microscopically examined, a *cerebro-spinal* nerve is seen to possess an outer covering of the connective-tissue already mentioned, and named the *perineurium*. Each nerve may be split up into *fasciculi* or bundles of fibres; and each fasciculus may in turn be resolved into its component fibres. Each fibre consists of a tubule, bounded by a clear, pellucid membrane within which the true *nerve-substance*—a transparent homogeneous matter—is contained. A nerve-fibre in fact resembles a clear glass tube filled with transparent fluid. After death, or when water, acetic acid, or other re-agents have been added to its substance, the nerve-fibre exhibits a division into three layers. Externally there is the *neurilemma*, or nerve-sheath; next comes the *medullary*

sheath, or *white substance* of Schwann; and internally lies the *axial* or *axis cylinder* of the nerve or *central band* of Remak. There also appears in the dead nerve-fibre a double outline that is wanting in the fresh state. That differences of a very material kind exist between the various parts of a nerve, there can be no doubt. Thus the *axis cylinder* can be readily stained with carmine, whilst the medullary sheath is impervious to it. The *axis-cylinder* is unaffected by chromic acid, while the medullary sheath is browned and rendered opaque by it. The medullated fibres vary in size. The very large ones measure about the $\frac{1}{1000}$ th of an inch in diameter, those making up the brain fibres as seen in the nerves near the spinal cord are much smaller, and may not exceed the $\frac{1}{1000}$ th or $\frac{1}{1250}$ th of an inch in diameter.

The second variety of fibres, named *non-medullated*, is seen in the *olfactory* and *sympathetic nerves*. These fibres also occur, however, in the cerebro-spinal system. These non-medullated nerve-fibres consist of pale greyish, translucent, and flattened fibres, each measuring from the $\frac{1}{1000}$ th to the $\frac{1}{2000}$ th of an inch in diameter. They do not possess a double contour, and their contents are uniform in appearance, while they have no 'medullary sheath' or 'white substance.' Nuclei are found in these fibres. Physiologists are agreed that the differences in structure and composition clearly point to a difference in the functions of the two kinds of nerve-fibres. Nerve-fibres usually run in an uninterrupted manner from the nerve-centre to their termination in the *periphery* or outer portion of the body, or in some other part. *Anastomosis*, or the union of nerves to form *plexuses*, is well seen in many parts of the body, and it has been supposed that the presence of a plexus gives to a nerve a wider and more efficient connection with the spinal cord. Nerves end in various ways, both at the periphery of the body and in nerve-centres. Nerves supplying muscles and membranes end in fine plexuses; some end in *touch-corpuscles*, *Pacinian bodies*, and *end bulbs*—organs associated with the sense of touch. Those in the eye and ear terminate in special cells; and in muscles special endings in *motorial end-plates* have been described.

The second elements in the N. S. have been already alluded to under the names of *cellular* and *vesicular* elements. Sometimes they are called *nerve-corpuscles*. The nerve-centres are made up of these, along with a proportion of fibres. *Nerve-corpuscles*, which form the essential parts of ganglia, the brain, and spinal cord, are in reality nucleated cells of a special type. Some are of simple form and rounded shape. Others give up a process at either end (*bipolar cells*), or numerous processes (*multipolar cells*). These cells are filled with fine granular matter, and are nucleated. There seems little doubt that the processes or branches given off from nerve-cells are means of communication with neighbouring cells.

In each ordinary nerve two sets of fibres indistinguishable from each other are found. One is named *centripetal* or *afferent*, and serves to convey impressions to the nerve-centres. The other, called *centrifugal* or *efferent*, serves to convey impressions from the nerve-centres to the periphery and other parts and organs of the body. The centrifugal fibres have been named *motor fibres* when the impulse they convey excites *motion* in muscles; *trophic*, when they influence nutrition through stimulating organs (e.g., salivary glands) devoted to this function; and *secretory*, when they affect the organs or membranes devoted to secretion. Centrifugal fibres are *sensitive* when they are connected with the production of sensation; or *inhibitory*, when they produce a restraining effect in the nerve-fibres. Nerve-fibres are mere conductors of nerve-force. They have no power of generating this force, and certain nerve-fibres will only respond in their own part to stimuli of certain kind. Thus the optic nerve is affected by light alone, and the auditory nerve only responds to or is excited by sound-waves. Nerve force has been estimated to travel along nerve-fibres in man at the rate of about 111 feet per second; other observers state the rate at 140 feet per second, while in cold-blooded animals the rate is of necessity slower. When a nerve is divided, its power of conducting impressions is destroyed, and it would appear, according to Waller, that the portion of the nerve lying between the point of division and the outward or peripheral end of the nerve undergoes changes of degenerative nature. The cut ends of a nerve, however, soon unite, and its conductivity and functions are restored with the perfection of its physical continuity. The chief *nerve-centres* are the brain and spinal cord, and the various *ganglia* or nerve-masses formed in connection with the sympathetic and cerebro-spinal systems. The function

of nerve-centres is that of producing or generating the *nerve-force* which is conveyed and transmitted by the nerves.

The *cerebro-spinal* and *sympathetic nervous systems* may be briefly described by way of conclusion. The former, as already remarked, consists of the brain (*Encephalon*) and spinal cord, with the nerves (*cranial* and *spinal*) which issue from these centres respectively. This system is enclosed within the bony case formed by the skull and spinal column. The brain of man, complicated as it may appear, is in reality constructed on a similar plan to that of all other vertebrata.

The typical vertebrate brain may be divided into three chief regions—a *fore*, *mid*, and *hind brain*—corresponding to the three divisions which the organ exhibits in the course of its development; but for the sake of greater simplicity we may regard any brain as consisting of some six or seven ganglia, or nerve-masses, disposed in a linear series. In many fishes this elementary condition of the brain is well seen. The first ganglia are the *olfactory lobes*, or those exercising the sense of smell. The second brain segment is formed by the *cerebrum* or true brain; the third by the *corpus striatum*; the fourth by the *optic lobes*, or those concerned in the sense of sight; the fifth by the *cerebellum*, or lesser brain; the sixth by the *pons Varolii*; and the seventh by the *medulla oblongata*, or upper part of the spinal cord. In some *Amphibia* (e.g. frogs) the cerebral hemispheres attain a better development, and appear in excess of the other ganglia. Reptiles and birds have these ganglia still further increased in size, and in Mammalia, but most distinctively in man, the cerebrum, or true brain, overgrows and overlaps all the other portions, so that in the human subject the two chief regions of the brain are the *cerebrum* and *cerebellum*.

The weight of an adult human brain is about 3 lbs.—varying from 48 to 50 oz. In man it makes up from $\frac{1}{12}$ to $\frac{1}{8}$ of the weight of the body, and its weight relative to that of the body is only exceeded by the brain of some birds and some of the smaller monkeys. In *absolute* weight man's brain exceeds that of all animals except that of the whale and elephant. The female brain weighs on the average less than that of the male. Cuvier's brain weighed 64 oz., Goodair the anatomist's weighed 57½ oz., Dr. Abercrombie's 63 oz., and that of Sir J. Y. Simpson 54 oz. The cerebrum is the seat of intelligence and will. Although the systems of mind-localisation hitherto formed are more or less deficient, yet the physiology of the brain is beginning to be well understood, so that in a few years we may hope to possess very definite information regarding the functions of different parts of the brain. The *cerebellum* discharges the function of *co-ordinating the movements of the body*. When this segment of the brain is removed from an animal, it remains perfectly intelligent; eats, and otherwise exhibits normal actions; but its

BRAIN OF A CON, viewed from above.—a, Medulla oblongata; b, cerebellum; c, optic lobe; d, hemisphere vesicle; e, olfactory bulb; f, optic nerves.

MESIAL SECTION OF HUMAN BRAIN.—a, Medulla oblongata; b, pons Varolii; c, fourth ventricle, and, behind it, valve of Vieussens; d, iter, and, behind it, corpora quadrigemina; e, pinal body; f, optic thalamus looking into the third ventricle, and, in front of it, an open passage from the third to the lateral ventricle, called *foramen of Monro*; g, left layer of septum lucidum bounding the fifth ventricle, and, beneath it, the fornix; h, posterior extremity of corpus callosum above the transverse fissure; i, optic nerve; k, pituitary body; l, one of the corpora albicantia.

The cerebrum is the seat of intelligence and will. Although the systems of mind-localisation hitherto formed are more or less deficient, yet the physiology of the brain is beginning to be well understood, so that in a few years we may hope to possess very definite information regarding the functions of different parts of the brain. The *cerebellum* discharges the function of *co-ordinating the movements of the body*. When this segment of the brain is removed from an animal, it remains perfectly intelligent; eats, and otherwise exhibits normal actions; but its

movements are erratic and indeterminate, and it appears to have lost all power of harmonising or co-ordinating the actions of its muscles. From the brain 12 pairs of cranial nerves—9 pairs according to English anatomy—are given off. These nerves, with their names and distribution, may be thus tabulated:—

ORDER.	NAME.	FUNCTION.
I. <i>Pak.</i>	OLFACTORY.	{ Exercises special sense —that of smell.
II. "	OPTIC.	{ Exercises special sense —that of sight.
III. "	MOTOR-OCULI.	{ Motor for all the mus- cles of eyeball save two.
IV. "	{ TROCHLEAR or PATHETIC.	{ Motor for superior ob- lique muscle of eye- ball.
V. "	{ TRIGEMINAL or TRIFACIAL (5th Nerve.	{ Sensori-motor; supplies Sensory branches to face, mouth, and part of tongue; and motor branches to masticatory or jaw-muscles.
VI. "	{ ABDUCENS (6th Nerve).	{ Motor to ext. rectus muscle of eyeball.
VII. "	{ 7th and 8th of Contin- ental Anatomists.	{ (1) FACIAL (in part).—Motor nerve of face. (2) AUDITORY. { Special sense—that of hearing.
		{ (1) GLOSSO-PHARYN- GEAL NERVES. { Special sense—taste.
VIII. "	{ 9th, 10th, and 11th of Continental Anatomists.	{ (2) PNEUMOGASTRIC or VAGUS. { Chest and abdomen. Sensory branches to pharynx, gullet, heart, lungs, and stomach, &c.
		{ (3) SPINAL ACCESSORY NERVES. { Motor to trapezius mus- cles of back, and muscles of neck, &c.
IX. "	{ 12th of Continental Anatomists.	{ HYPOGLOSSAL NERVES. { Motor to muscles of tongue.

The *spinal cord* extends in man from the *foramen magnum*, or hinder aperture of the skull, to a point opposite the body of the 1st lumbar vertebra. It attains a length of from 15 to 18 inches, and is cylindrical in shape, but flattened on its front and hinder surfaces. It is enlarged (*brachial or cervical enlargement*) between the 3rd cervical and 1st dorsal vertebra; and again (*lumbar enlargement*) opposite the last dorsal vertebra. From the former point the nerves of the upper limbs, and from the latter those of the lower limbs, are given off. The spinal cord is divided through its length almost completely into two symmetrical halves, which are united in the middle line by a *commissure*. The *anterior fissure* separating these is shallower than the *posterior*. Each half of the cord is further marked by two longitudinal furrows. The cord ends below in a slender filament named the *filum terminale*, which is surrounded on each side by nerves forming the *cauda equina*. A minute canal, formed as already described in the development of the nervous system, runs through the centre of the cord; this canal being lined by a layer of *ciliated epithelial cells* (see *EPITHELIUM*). The cord consists of *grey* and of *white* nervous matter. The latter lies to the outside, and forms the *columns*. The grey matter is internal and is surrounded by the white. It exhibits a crescentic shape in each half of the cord. The proportions of grey to white matter vary in different parts of the cord, the latter increasing in extent from below upwards, and being most plentiful in the neck-region. The spinal cord contains both nerve fibres and nerve-cells. The white matter is fibrous in its nature; the grey matter contains connective tissue, blood-vessels, nerve-fibres, and nerve-cells. It is noteworthy that the position of the grey and white matter in the brain is reversed from that which obtains in the cord; the grey matter being external in the brain, and the white being internal. The grey and white substances of the nervous centres appear to have widely different functions. The grey matter appears to be that through which sensation is alone manifested, whilst motor impressions are also conveyed by the grey substance. The white matter, on the contrary, appears to convey motor impressions only. The *spinal nerves*, originating from the spinal cord, number 31 pairs. They pass outwards to supply the various parts of the body

SECTION OF SPINAL CORD AND ITS NERVES.—*pr*, Posterior, and *ar*, anterior roots of spinal nerve; *g*, ganglion on posterior root.

through the *intervertebral foramina*, or special apertures existing between the vertebra. The first 8 pairs are named *cervical*; then follow 12 *dorsal*, 5 *lumbar*, and 5 *sacral* pairs, and 1 *coccygeal* pair. Each spinal nerve arises by two roots, named respectively *anterior* and *posterior*—the latter being the larger of the two. The posterior root bears a ganglion, and just behind the ganglion the fibres of the two roots fuse together, so as to form a single spinal nerve. Sir Charles Bell's great discovery of the functions of the two roots revolutionised our knowledge of the physiology of the N. S. He discovered by experiment that if the posterior roots of one of the spinal nerves supplying the limbs be divided in a living animal, the animal will lose all sensation in the parts supplied by the nerves, while the power of motion will remain unimpaired. But if the anterior root be cut and the posterior left intact, the animal will lose all power of motion in the part, but will retain its sensation or feeling. This discovery clearly showed that the *anterior fibres of the spinal nerves supply power of motion to the parts to which they are distributed, while the posterior roots supply sensation*. Hence these roots are named *motor* and *sensory* roots respectively. In every spinal nerve we therefore find fibres, the function of which is to convey impressions from the nerve-centres (cord or brain, or both) to outward parts, these being *motor* fibres; and others which transmit impressions to the nerve-centres; these latter being *sensory* fibres. The correspondence of these names with the terms *centripetal* and *centrifugal*, already defined, is apparent.

The *Sympathetic N. S.* consists of two nervous cords bearing ganglia, and which lie one on each side of the spine. Each cord extends from the base of the skull to the end of the spine. In the dorsal, lumbar, and sacral regions of the spine, one ganglion exists almost for each pair of spinal nerves, and each of the latter nerves is connected with the sympathetic system by connecting twigs. Below the two sympathetic cords unite in a ganglion named the *ganglion impar*, lying in front of the coccyx. There are three ganglia in the neck. From this system of nerves branches are supplied to the heart, lungs, stomach, and other viscera, and especially to the blood-vessels; the nerves supplying the latter constituting the *vaso-motor nerves*. Summed up in the briefest possible manner, the functions of the sympathetic system may be said to include the regulation of these processes which are involuntary, or not under the command of the will. Thus the vaso-motor nerves regulate the movements of the blood-vessels; certain branches of the sympathetic regulate the movements of the heart; and the movements of the viscera in digestion appear to be controlled chiefly by fibres derived from the sympathetic system.

Diseases of the N. S.—In a strictly scientific classification of disease it would probably be found that the greater number of diseases with which the human frame is afflicted are diseases of the N. S., either depending on primary lesions or secondary affections; but many of these diseases are necessarily obscure during life, and this obscurity is often not removed by post-mortem examinations, so that a strictly scientific classification is impossible with our present means of diagnosis. The following are the principal diseases of the brain:—*Cerebral anemia* may be due to sudden hæmorrhage, to diseases of debility, or to insufficient diet, the symptoms being giddiness, ringing and buzzing in the ears, paleness, faintness, and sometimes convulsions and coma. *Cerebral congestion* may be active or passive, as in diseases which obstruct the circulation. In the active form the capillaries and large blood-vessels are enlarged, and in the passive form the veins are generally distended. In both conditions there is pain, giddiness, and confusion of intellect, but in the former there is in addition irritability and sleeplessness, and in the latter mental torpor and drowsiness. *Embolism and Thrombosis*, occluding the vessels at a point beyond the circle of Willis, lead to red softening and subsequent degeneration of the tissue of the brain. In embolism, which is usually associated with valvular disease of the heart, the onset is sudden, but in thrombosis, depending on advanced age, and feebleness of the heart's action, the symptoms are slowly developed. *Degeneration* of the brain substance, or of the coats of the vessels; miliary or larger aneurisms, and diseased states of the blood, as in purpura, may cause rupture of the vessels and extravasation of blood. Inflammation of the membranes of the brain, or Meningitis (q. v.), affects secondarily the brain substance, and the brain substance itself may be

inflamed, causing *Cerebritis* or *Encephalitis* (q. v.). These diseased conditions frequently terminate in dropsy of the brain and membranes, as in *Hydrocephalus* (q. v.). Tumours of the brain may be vascular, parasitic, cancerous, tubercular, or syphilitic, and in addition to their own specific action, they grow at the expense of the brain, which in health nearly fills the cranial cavity. The brain and spinal cord are subject to grey degeneration of the nerve tissue, with increase of the interstitial tissue in areas here and there. In cerebral softening, variously designated *white*, *yellow*, or non-inflammatory softening, the nerve cells undergo fatty degeneration; but in *red* or *inflammatory softening* the nerve substance is disintegrated and mixed up with the products of inflammation. See also *SCLEROSIS*. Diseases of the N. S., having their seat in the spinal cord, are *spinal meningitis*, and *myelitis*; *hamorrhages* into the spinal cord; *congestion*, and *softening*. *Cerebro-spinal fever*, sometimes called *epidemic cerebro-spinal meningitis*, consists in an inflammation of the membranes, and sometimes also of the substance of the brain and spinal cord.

NEURALGIA is the term used to denote those diseases of the N. S. which, in so far as can be ascertained, are not due to diseases of the brain or spinal cord, but which have their seat in the nerves themselves. Different names are given to these diseases, according to the nerves affected, or to their site. Thus we have *tico-doloureux*, *sciatica*, *lumbago*, and *pleurodynia*. There are many diseases of the N. S. of an obscure nature, which are referable to *Hysteria* (q. v.). Spinal irritation, or spinal tenderness, is an affection of this class, and as it may arise from a variety of distinct conditions, such as disease of some part of the spinal cord, uterine disease, chronic disease of the intestinal viscera, &c., its diagnosis is not very definite.

The principal diseases of the N. S. are described under their respective names, as *Apoplexy*, *Epilepsy*, *Chorea*, *Sunstroke*, *Paralysis*, *Tetanus*, *Hydrophobia*, *Hysteria*, &c. See *Romberg on Diseases of the N. S.*, translated by Dr. Sieveking, and *Diseases of the N. S.*, by Dr. Althaus (Lond. 1877).

Ness (Scand. *nas*, 'a nose or cape'), a frequent suffix of the Norse names bestowed by the old sea-rovers on the spits and headlands of the English and Scottish coasts, as *Sheerness*, *Fife Ness*, and *Caithness*, *Grinez* in France, and the *Naze* in Essex. Norway presents us with variants of the same word.

Ness, Loch (Gael. 'lake of the waterfall'—probably of *Foyers*), in Inverness-shire, Scotland, extends in the valley of *Glenmore* for a distance of 24 miles from N.E. to S.W., and nowhere exceeds 2 miles in breadth. It is 130 fathoms deep, on account of which it never freezes. The *Morrison*, *Oich*, and *Foyers* (q. v.) are its chief feeders, and it is drained into the *Moray Firth* by the river *Ness*. The scenery of the loch, though wild and impressive, lacks in variety.

Nesselro'de, Karl Robert, Count, a celebrated Russian diplomatist of German descent, was born 14th December 1780, at Lisbon, where his father was Russian ambassador. He became an *attaché* of the Russian Embassy at Berlin (1802), passed to Stuttgart, thence to the Hague (1804), and after the Peace of Tilsit became (1807) counsellor to the Russian Embassy at Paris. After the rupture in 1812 he was made a secretary of state. He actively promoted the treaties between the allied Powers of 1813 and 1814, signing the Peace of Paris (30th May 1814), and played a prominent part at the congresses of Vienna, Aachen, Troppau, Laibach, and Verona. In 1821 N. became Foreign Minister, and, amid the political complications of the next thirty years, he contributed greatly to increase the influence of Russia. In accordance with the instincts of his race he favoured the 'German party' in the Russian empire. In 1829 he was made Vice-Chancellor, and in 1844 Chancellor of the Empire. Before the outbreak of war in 1853 N. counselled a pacific policy. He resigned office 20th March 1856, and died at St. Petersburg, 23d March 1862. His *Autobiography*, written in French, was published soon after his death. A German version appeared in 1866.

Nest (Old Eng. *nest*; Comp. Welsh *nyth*, Gael. *nead*, Lat. *nidus*, and Sans. *nido*), the name given to the structures which various animals prepare, either as a habitation, or for the production and upbringing of their young, or for both of these purposes. It is of course in the case of birds that the art of N.-building is best seen. The variety of form, materials employed, and situations selected for the N., would require a large volume for their full treatment. Every gradation may be traced in the

perfection of this art in birds, from the simple cavity scooped out in the ground by many sea-birds, to the wonderful product of the dexterity of the tailor birds. Among *Mammalia* (q. v.) some species of mice and other Rodents (such as squirrels, &c.) make nests, and under this designation may perhaps be also included the structures of certain monkeys (e.g., orangs) in trees. Some reptiles (e.g., particular species of snakes and lizards) are known to collect materials and to arrange these in a rough fashion around their eggs; and among the fishes the familiar sticklebacks are true N.-building forms. The gobies, goramy, and other fishes also construct nests of rude character. Among *Invertebrata*, various insects (e.g., wasps, bees, hornets, ants, termites, &c.) are well known as N.-builders. Some spiders (e.g., the mason-spiders) build habitations of very definite kind, and the well-known trap-door spiders (*Mygale*) construct a true N., the aperture of which is provided with a movable lid. The *Argyroneta*, a water spider, builds a N. in the form of a diving-bell, and ascends periodically to the surface for a supply of air.

Nestor, son of Neleus and Chloris, and husband of Eurydice according to one legend; according to another, of Anaxibia, the daughter of Cratæus. Heracles invaded the dominion of Neleus and slew all his sons except N., who had taken refuge among the Geronians. N.'s prowess was conspicuous in the wars with the Arcadians, Eleians, and Centaurs. According to Ovid, he was engaged in the chase of the Calydonian boar and in the Argonautic expedition. His fame, however, is derived chiefly from the Homeric poems, in which he is celebrated as the wisest of all the heroes who went against Troy. He is said to have gone thither with a fleet of sixty ships, and to have been the most excellent and eloquent adviser among the chiefs, Ulysses not excepted. After the fall of Troy N. was privileged to return to his own land, to rule over a peaceful people, and to enjoy a ripe old age, surrounded by his brave and intelligent sons. Pylos in Messenia claimed to be the city of his birth, and the house in which he was believed to have lived was shown there in the time of Pausanias.

Nestorians, a heretical sect of the early Church, derived their name from Nestorius (q. v.), who was condemned by the Council of Ephesus (431), under the presidency of Cyril of Alexandria, before the arrival of the Eastern bishops. When they arrived they elected John, bishop of Antioch, their president, and deposed Cyril and his principal abettor, Memnon of Ephesus, who, however, were reinstated by the Emperor. The consequence was a separation of the Church in the East from the rest, especially Egypt. There was a want of unanimity, however, among the Orientals, which proved a source of weakness in the contest. Thus Rabulas, bishop of Edessa, interdicted the writings of Diodorus of Tarsus and Theodore of Mopsuestia, which were the source of Nestorius' opinions. Great opposition to this was offered by the theological school in Edessa, and when some of the teachers betook themselves to Persia they were confirmed in their attachment to Nestorianism by Barsamas, bishop of Nisibis (435-489). The school of Edessa was finally destroyed in 489, and those connected with it fled to Persia; and Pheroses, king of that country (461-488), favoured the separation of the Persian Church from that of the Roman Empire for political reasons. They called themselves Chaldean Christians, receiving the name of N. from their opponents; but they also spread into India, where they took the name of Thomas Christians, and even into China and Tartary. They still exist in the East, but now agree in the main with the Romish Church on the Incarnation, although they express the doctrine in different terms. See Gieseler's *Lehrbuch der Kirchengeschichte* (Eng. trans. 1855).

Nestorius, a Syrian by birth, and a disciple of Theodore of Mopsuestia, who, with Diodorus of Tarsus, had maintained the complete human nature of Jesus in opposition to the Monophysitism (q. v.) of Appollinarius (q. v.), was bishop or patriarch of Constantinople from A.D. 428. He sympathized with those who wished distinctly to separate the two natures of Jesus from fear of annihilating the divine nature by lowering it, or of annihilating the human nature by taking from it any of its distinctive elements. Anastasius, a presbyter of Constantinople, in 428 preached against the use of the phrase *Theotokos* ('Mother of God') as applied to the Virgin Mary, because God could not be said to be born of a human creature. N. afterwards maintained the view of the presbyter. He held that the divine and the human natures of Christ ought to be distinctly separated, and

admitted only a junction of the two and an indwelling of the Deity. Cyril, patriarch of Alexandria, at once came forward as the champion of orthodoxy, and maintained the perfect union of the two natures. N., in reply to the letter of Cyril, accused the latter of confounding the two natures of Jesus. Cyril, however, succeeded in enlisting Celestinus, bishop of Rome, and in inciting the prejudices of the Western Church generally, against N., by misrepresenting his doctrine as a form of Pelagianism (q. v.); and both at Alexandria and at Rome he was accused of heresy. To settle the dispute the Emperor (Theodosius II.) convoked an Ecumenical Council at Ephesus (431), which condemned N. (who afterwards died in exile, 440), and decreed that Christ was at the same time God and man, and that in the unity of his person the two substances, divine and human, were not simply annexed but united.

Nests, Ed'ible Birds', are the gelatinous nests of probably more than one species of *Collocalia* birds, closely allied to the swallow, and known as the salanganes. The birds are found wide-spread over Eastern Asia, the Indian Archipelago, and many of the South Sea Islands, and they attach their nests to rocks and caves. The nests are small, of a dirty white colour, and are composed of gelose, a gummy substance similar to what is obtained from a species of seaweed. They are taken thrice yearly, and two months are said to be occupied by the swallow in constructing a new abode. The Chinese esteem E. B. N. a very great luxury in soups, paying from 30s. to £7 per lb. for them. An extensive and profitable trade in the nests is carried on between several of the E. Indian Islands, Siam, and Chinese ports. The annual value of the E. B. N. introduced into China is estimated at £200,000.

Net (Old Eng. *net*, *nyt*, from *cnytan*, 'to knit'; Ger. *netz*), a meshed fabric, made with twine or thread, used for catching fish or birds, for protecting garden beds, and for other purposes. Fishing-nets were made in remote ages, as is proved by frequent allusions to them in the oldest known writing and their representation on the wall-paintings of ancient Egypt. Six varieties of nets are mentioned by classical authors, and among these two answering to the casting-net and sea-net of modern times, frequently occur. The same process of making nets by hand, namely, *netting*, was no doubt pursued in ancient as in modern times. Netting consists in forming a line of string into a series of regular meshes in rows and knotting the twine at every intersection. The instruments, used for this purpose are the *pin*, a piece of wood like a flat ruler, and the *needle*, a wooden tool resembling at each end a two-pronged fork, round which the twine is wound lengthwise. Loops are formed by the aid of the former implement, and by passing the latter through these, the interlacing and knotting are effected. Knotting prevents any alteration in size of the individual meshes, and affords security against injury to one or more of them affecting the usefulness of the adjoining meshes in retaining objects caught in them. Hand-netting formed at one time an important branch of industry in many coast towns, but except in a few isolated fishing-villages it is now seldom practised. Notwithstanding their cheapness, hand-made nets were unable to compete with machine-made nets, which now are principally manufactured by beautifully-contrived machinery, at Musselburgh, Kirkcaldy, and other towns in Scotland, and at Bridport in England. Within a few years cotton has been introduced as a substitute for hemp and flax for net-making. Nets of cotton possess advantages in lightness, invisibility, and ease of working in water over the stout and heavy hemp-nets. Hempen twine is, however, more durable than cotton, and the best quality from Manila is still retained for trawl nets. Hempen nets are preserved and strengthened by exposure to the action of oak-bark or catechu liquor, while those of cotton are, when new, treated with linseed-oil, and afterwards 'barked' or dressed with tar. The different kinds of fishing-nets and their special uses are detailed under the head **FISHERIES**.

Neth'erlands, Kingdom of the (Dutch *Nederlanden*, 'low lands'; Ger. *Niederlande*; Fr. *Pays Bas*), or **Holland**, is bounded on the N. and W. by the North Sea, S. by Belgium, and E. by Rhenish Prussia and Hannover, in lat. 50° 46'—53° 36' N., and in long. 3° 22'—7° 16' E. Its extreme length from N. to S. is 195 miles, and its breadth from E. to W. 110, while the coast

line, including the Zuider Zee and lesser indentations, has a length of some 500 miles. Luxembourg (q. v.) has a separate constitution and legislature. The areas and populations were as follows, according to an official return at 1st January 1876:—

Provinces.	Areas in Sq. Miles.	Pop. 1876.	Chief Towns.
Brabant, North . . .	1960	451,095	Bois-le-Duc.
Gelderland . . .	1964	448,820	Arnhem.
Holland, North . . .	955	748,162	The Hague.
Holland, South . . .	1162	629,345	Haarlem.
Zeeland . . .	681	185,628	Middelburg.
Utrecht . . .	532	184,084	Utrecht.
Friesland . . .	1253	313,804	Leeuwarden.
Overijssel . . .	1283	265,144	Zwolle.
Groningen . . .	915	238,662	Groningen.
Drenthe . . .	1017	112,221	Assen.
Limburg . . .	840	232,562	Maastricht.
	12,562	3,809,527	

Physical Aspect.—The southern and greater portion of the N., which may be regarded as the Delta of the Rhine, is irregularly shaped, and in surface is both level and low. Dutch landscape is tame, but has a certain quiet pastoral beauty. The wide expanses of meadow, clad with luxuriant verdure, and richly stocked with herds of well-fleshed kine, are intersected by canals, and relieved by quaint windmills and clusters of trees. In the vicinity of the towns the canals are fringed with willows and poplars, and the characteristic villas are girt with gardens and parks. The N. are traversed from E. to W. by the main branches into which the Rhine separates soon after leaving Rhenish Prussia, namely the Waal and the Lek, which enclose the long fertile tract of Betuwe ('good meadow land'; Lat. *Batavia*). The Maas, after a northerly course through Limburg and Brabant, flows W. and joins the Waal opposite Groningen and a little above Biesbosch; while the Lek, some 6 miles below the point of its departure from the Waal, sends off the IJssel in a northerly direction towards the Zuider Zee. From Belgium in the S.W., Holland receives the estuary of the Scheldt, which at once separates into the Ooster Scheldt and De Hond or Wester Scheldt (more correctly N. and S. Scheldt). The estuaries of these large rivers, split into a maze of streams, encircle a cluster of in-shore islands, of which the chief are Voorne, Goeree, Schouwn, N. and S. Beveland and Walcheren. The principal channels by which the Waal finds its way to the North Sea are the Holland Diep, dividing into the Haringvliet and Kammer, and the Oude Maas, which joins the streams into which the Lek divides. The islands of the N. are simply parts of the low-lying coast, cut off by the rivers when their courses have been changed by floods. The Biesbosch ('rush-bed'), a waste of morass and waters, through which the Waal sends part of its waters to the Holland Diep, was formed by the breaking of a sea-wall in 1421, when 72 villages were laid under water. The Zuider Zee (q. v.), which occupies almost the heart of Holland, and is a shallow bay, 80 miles long, and 40 broad, and 1365 sq. miles in extent, was formed out of an inland lake by successive invasions of the sea, which culminated in a great flood in 1247. The islands at its mouth—Texel, Vlieland, Terschelling, and Ameland—stretching N.E. in a chain from the peninsula of N. Holland, are merely the unsubmerged rising grounds of the original plain. In the extreme N., and partly separating Holland from Hannover, is the Dollart Zee, an inlet formed in 1277 by a flood which destroyed 33 villages and 100,000 lives. In many parts of the N. the surface is below the level of the adjacent canal or river, and even of the sea; and this is the chief cause of frequent inundations. A great part of the coast is defended by sand-hills about 50 feet high, and these the natives protect by sowing them with binding grasses. In other places enormous dykes have been built at the public expense, some of granite blocks from Norway. Every precaution is taken to preserve these barriers; e.g., the stork is protected by law, because it is the enemy of the frogs and worms which injure the sand-hills. Dykes are also built along the banks of the great rivers, with sluices at intervals, by means of which the country can be laid under water at the approach of an enemy. Much of the area formerly covered by lakes has been drained and rendered arable, and such tracts are called 'polders.' The only large portions of the country still unused for agricul-

ture or grazing are the Bourtanger morass in the N., and the sandy heath of Peel in the S.E. Only in Gelderland are there any hills, and these are of but slight elevation.

Hydrography.—Without any considerable river entirely within her own borders, Holland possesses in the branches of the Rhine and Maas, supplemented as these are by extensive canals, a more complete system of water communication than any other country. Of the canals, the principal are the North Holland Canal, 52 miles long, 120 feet broad, and 20 feet deep, connecting Amsterdam with the North Sea at Helder; the Voorne Canal, from Voorne to Helvoetsluis, shortening the outlet from Rotterdam; and, by far the most important of all, the North Sea Canal, or Amsterdam Canal, giving Amsterdam a direct waterway of only 15 miles to the North Sea through the Y, the Wijkmeer, and the narrow Neck of Holland. This great work, now (1877) nearing completion, is 14 miles long, 90 feet broad, and 25 feet deep, and terminates in a large artificial harbour formed by piers of concrete. The draining of the Y and Wijkmeer into the canal will set free extensive polders. In this, and similar works, the drainage is now assisted by powerful Appold centrifugal and force pumps. Another triumph of hydraulic engineering in Holland was the draining of the Haarlem Lake (q. v.), completed in 1852. Recently it has even been proposed to drain the southern part of the Zuider Zee (q. v.), and the task is likely to be taken up by Government before long. The construction and maintenance of canals and dykes are intrusted to the officers of the Waterstaat, who expend about half a million sterling.

Climate, Botany, and Agriculture.—The climate is humid and variable, and to foreigners disagreeable if not dangerous. Cold foggy weather is sometimes quickly followed by great heat, bringing with it agues and fevers. The winds blow almost incessantly, and occasionally with great violence, overwhelming the land with fogs. The sky is generally overcast, there being rarely more than forty bright days in the year. Winter is usually severe, and though little snow falls, the frosts are intense. The mean annual temperature at Amsterdam is 49° 8', while in winter it is 36° 6', and in summer 64° 4'; the yearly rainfall is 26 inches, and number of rainy days 170. Although there are no natural forests, plantations of oak, elm, beech, &c., are by no means rare. Aquatic plants, as might be expected, are unusually numerous. Holland has been called the China of Europe, on account of the great skill and industry required to render the natural resources adequate for the support of the inhabitants. The soil near the coast is chiefly sand mixed with turf, in other parts a deep loam, and is everywhere cultivated, generally in small farms, with the utmost care. The principal grain crops are rye, buckwheat, barley, and oats, together with some wheat in the S. provinces. Other important crops are potatoes, flax, hemp, rapeseed, clover-seed, madder, chicory, mustard, beetroot, hops, and tobacco. Horticulture has been carried to great perfection, especially at Haarlem, and there is a large export of the bulbs of hyacinths, tulips, &c. But Holland is chiefly a grazing country. The cheese of Gouda, Leyden, and Edam is famous. Game is largely exported to London, especially hares, wild ducks, partridges, pheasants, plovers, and snipes. Holland is the paradise of the swan and the stork.

Geology and Mineralogy.—The geological formations in the N. are almost exclusively the Tertiary or Post-Tertiary, and consist of banks of sand and marine shells, and beds of peat and clay, supporting an alluvial soil, deep, rich, and clayey. Coal is wrought only in Limburg; and in the same province is found a soft sandstone, used in building. Stones of any considerable size are seldom seen in the soil, and building stones are imported from Norway for the erection of dykes, piers, and other important structures. For want of stone, brick is used for paving as well as building. The timber used in building is floated down the Rhine from the German forests in immense rafts, sometimes 1000 feet long, and directed by some hundreds of labourers. The N. are comparatively poor in minerals; the chief are potter's clay, brick-clay, fuller's earth, a little bog-iron, and immense deposits of turf.

Industries, Commerce, &c.—Holland has no large manufacturing centre; yet the seats of industry, though small, are numerous. Among the chief manufactures are the linens known as 'Hollands,' the gin which goes by the same name, the pottery of Delft, the cheese of Gouda, the Turkey-red yarns and dyed silks of Roermond, and the carpets of Utrecht, Arnhem, and Breda. Notable also among the industrial products are woollens,

damasks, calicoes, shirtings, striped dimities, paper, leather, glass, firearms, tobacco, snuff, tobacco-pipes, saltpetre, and cordage. There are also large shipbuilding yards, sugar-refineries, breweries, and type-foundries. The diamond-cutting trade of Amsterdam is the largest in the world. Along the coasts there are valuable cod, turbot, sole, oysters, and other fisheries; the rivers yield abundance of salmon, eels, perch, &c.; a productive herring-fishery is carried on in various parts of the North Sea, and on the N. coast of Scotland; while several whalers annually visit the Greenland seas. The position of Holland at the mouth of the Rhine, and her possessions in various parts of the world, have long given her the command of a great foreign trade. In 1875, in addition to the purely transit trade, the exports amounted in value to £44,914,242, and the imports to £59,903,854. In 1876 the exports to Great Britain alone were valued at £16,602,154, and the imports therefrom at £18,707,800. The trade is chiefly with Great Britain, Germany, Belgium, Java, and France. Chief among the articles of export from the N. to Great Britain (1875) were butter to the value of £1,917,910, live animals, principally cows and sheep, to the value of £2,124,935, and cheese to the value of £1,078,594. From Great Britain the chief imports were cotton goods (including yarn) of value £3,656,916, woollen goods of value £2,750,068; and wrought and unwrought iron, of value £1,563,831. Other leading exports, besides those already given are coffee, sugar, raw cotton, tobacco, spices, and dried fruits (mainly the produce of the Dutch colonies), which are exchanged for the grain, wool, manufactured goods, timber, wine, and brandy of other European countries. At the end of 1875 the mercantile navy of Holland consisted of 1835 vessels, of 526,527 tons, including 86 steamers of 76,827 tons. In 1876 the kingdom was traversed by 1036 miles of railway, and 2150 miles of telegraph lines.

Colonies.—The colonial possessions have a total area of some 666,700 sq. miles, and a pop. (census of 1874-75) of 24,386,991. On its separation from Belgium in 1830, Holland retained all the colonies. The island of Java, by far the most important, is the only colony yielding a profit after defraying the cost of its own government and defence. The chief colonies are Java, parts of Sumatra, Borneo, the Celebes, the Moluccas, Timor, Bali, Lombok, Billiton, Rian, Banca, the western part of New Guinea, Surinam or Dutch Guiana, Curaçao, Aruba, the S. half of St. Martin, Buen-Ayre, Eustatius, and Seba.

Government, Army, Navy, &c.—The government of the N. is a constitutional and hereditary monarchy, and the legislative power is vested in the king and the States-General, comprising an Upper House of thirty-nine members elected by the provincial states, and a Lower House of eighty members elected by the ballot of all natives who pay £1, 13s. in taxes. The Lower House alone has the initiation of new laws. In 1877 the revenue, derived chiefly from indirect taxation, amounted to £3,666,037, and the expenditure to £10,017,849, while the public debt was £76,016,012. In 1877 the regular army comprised 60,867 rank and file, and 2063 officers; the colonial army had a total of 33,996, of whom 1416 were officers. There is besides a militia (*Schutterij*) numbering 100,323 more. In the latter 14,461 were Europeans, 19,170 natives of the colonies, and 365 Africans. The sum voted to the war department in 1875 was £1,541,926. The royal navy comprised (1876) 22 ironclads with 533 guns, 7 frigates, 9 corvettes, 19 avisos and gunboats, and 10 paddle steamers. The only large ironclad, a double-turret ship, 245 feet by 48, and armed with four 35-ton Armstrong guns, was built at Amsterdam, and launched in August 1876.

Religion and Education.—Both Protestants and Roman Catholics are salaried by the State. The latest return gives 2,074,734 Calvinists, 68,067 Lutherans, 1,313,052 Roman Catholics, 68,003 Jews, and 55,725 of various other Christians. The government of the Calvinistic or Reformed Church is Presbyterian; the Roman Catholics are under an Archbishop of Utrecht and four bishops. Several British Presbyterian ministers whose churches here are incorporated with the Dutch Reformed Church are paid out of the public funds. An unsectarian 'Primary Instruction Law' was passed in 1857, and under it there were, in 1871, 2608 public schools and 1119 private schools. There are also 81 middle-class schools, 55 Latin schools, a polytechnic institute at Delft, 5 Roman Catholic and 3 Protestant seminaries, and the three universities of Leyden, Groningen, and Utrecht, with a total of 1339 students.

Ethnography.—The Dutch, a people of purely Teutonic race, are distinguished by a cleanliness that has become proverbial, by an industry at once ingenious and persevering, and by great practical sagacity, no less than by an exceptionally phlegmatic temperament. They are strongly animated by a love of home and country, rising into a keen sense of national independence. Remarkable for their nautical skill, they meet danger with singular courage and composure. Their cleanliness is rendered necessary by the exceeding humidity of the climate, which would otherwise consume their iron with rust and their wood with mould. During the three months when all the canals and several of the rivers are frozen over, the whole nation may be said to move about on skates. Even children skate to school, and women to market with baskets of eggs on their heads.

Language.—The Dutch language is a dialect of Low German. Its oldest form is found in the so-called 'Karolingian Psalms' (800 A.D.), first published by Von der Hagen at Breslau in 1816, the idiom of which is closely allied to the Old Saxon of the *Heliand*. 'Middle Dutch' dates from the poem *Reinaert de Vos*, written probably in the last half of the 12th c., and extends to the 16th c. It was called by the French 'Thyois,' or 'Tiesche,' and by those who spoke it 'Dietsch' (whence the English name 'Dutch'); while 'Vlaemsch' was as yet the common designation of the provincial *patois*. In the third, or modern period, French influence in the S. provinces, and in the N. the impulse of national freedom, further widened the breach between Dutch and Flemish.

Literature.—The literature of the N. prior to the 16th c. being already noticed in the article on FLEMISH LITERATURE (q. v.), our account of Dutch literature begins at that period. 'Though the exercises of the 'Rederijker' had small æsthetic results, their influence on politics and religion was considerable, and in the 16th c. they were therefore suppressed by the Spanish government. Again restored, they declined in the 17th c., and in the 18th altogether ceased. Amsterdam was their chief seat, after the great emigration from the South had made it the national capital. Amidst the crowd of rhetoricians and psalm-writers of the 16th c., Anna Bijns (born 1494) stands out as the one real poet of genius, and with her modern Dutch literature really begins. Her *Ketrefreinen*, or 'Refrains' (new ed. by Bogaers and Hielten, Rotterdam, 1876), are modified *chans-royals*, breathing a high-souled passion, yet full of graceful imagery, and moving with a new and joyous freedom in elaborate harmonies. Dirk Coornhert (1522-90) and his friends Roemer Vischer and H. I. Spiegel wrote in prose and poetry, and counteracted the Gallicising tendency of the South. The University of Louvain (founded in 1425) was a centre for Catholicism and humanistic studies, Leyden (founded in 1575) for the Protestant spirit. Scaliger, called to the latter in 1592, gave a freer course to classical study. The rich fruit Holland gained from the *Renaissance* is seen in the great names of the 17th c. History and learning were represented by Hooft (q. v.), Grotius (q. v.), Brandt (1626-85), Pontanus (1571-1640), Ditzema, Gronovius, Heinsius, and Vossius; poetry by Camphuysen, Hooft, Van den Vondel (q. v.), Huyghens (1596-1686), and Jakob (called 'Father') Cats (1577-1660); and the drama by Bredero (1585-1618), Brandt, Jaachim Ondaan (d. 1692), Reimer Anslø (d. 1669), and J. A. van der Goes (d. 1634). The inspiration of the war of liberation was succeeded by a disposition to enjoy the welfare it brought about. The Revocation of the Edict of Nantes (1685) brought to Holland many French exiles, whose influence contributed to form a school devoted to the unities and the criticism of Boileau. In the *Kunstgenootschappen* ('poetic clubs') of the period, Pels, Rohaans (d. 1710), Hoogvliet (d. 1763), and Feitama (d. 1758), were of this section, while Poot (d. 1733), Broekhuysen (d. 1707), were the exponents of a more national feeling. Van Winter (d. 1795) and his wife L. V. van Merken wrote dramas and descriptive poetry; Willem Z. van Haren (d. 1768), a romantic epic; his brother Onno the lyric tale *De Geusen*. Langendijk (d. 1756) was distinguished in comedy; Focquenbroch (d. 1796) in burlesque; and Van Essen's *Hollandsche Spectator* (1731-35) formed modern Dutch prose after an English model. To the great advance in German literature during the last third of the 18th c. is due a movement towards stricter truth to nature, led by the lyrists Van Alphen, Rhyms Feith, and Bellamy, whose ballad of *Rosje* (about 1770) is perhaps the most beautiful in the language. History had already reached a higher stage in the 18th c. in the hands of Wagenaar,

Stijl, Te Water, Meermann, Engelbert, and Scheltema; and in the 19th was written by Kluit, Van Kampen, and Bilderdijk (also famous as a poet); more recently by De Jonge, Van den Bergh, and Van den Brink (d. 1865). The history of literature has been treated by Van Vries, Willems, Van Kampen, Siegenbeek, Geysheek, and Van der Aa. The chief poets of the 19th c. are Helmers, Kinker, Hendrick Tollens, Loosje, Loots, Ten Kate, Polgieter, and De Bull. Van Lennep, Bogaers, Meyer, Ter Haar, and Beets represent the Romantic school in romance. The chief novelists are Oltman ('Van der Hage'), Tonssaint, Cremer, Schimneel, Brouwer, Linde ('Vater Smits'), and Douwes Dekker, author of *Max Havelaar*. In spite, however, of the vigour and originality of the national literature, no Dutch authors can be said to have gained a European reputation except those who wrote in Latin, the most illustrious of whom are Erasmus, the father of the Renaissance, Grotius the famous jurist, Spinoza the philosopher, Arminius the theologian, and Boerhaave, the first physician in the world at the beginning of the 18th c. See Jonckbloet's *Geschiede der Nederlandschen Literatuur* (2d ed. Leips. 1873).

For an account of the Dutch school of painting, see the articles BELGIUM and PAINTING.

History.—The earliest known inhabitants of the N. were the Batavi (q. v.) and the Frisians (q. v.), who were subdued by the Romans and subsequently by the Franks under the Karolings (q. v.). On the growth of the feudal system the country became broken up into many small principalities, of which the chief were the duchies and countships of Brabant, Flanders, Gelderland, Holland, Zeeland, and Hennegau, and the archbishopric of Utrecht. The remote position of the country made the feudal lords more than usually independent of the royal or imperial authority, which was met in particular with a keen resistance by the counts of Holland and the archbishops of Utrecht. By the marriage of Philippe the Hardy (1369) Flanders passed to Burgundy, and later the Burgundian dukes, either by force or inheritance, acquired the whole country. 'With the advent of the Burgundian family the power of the commons has reached so high a point that it is able to measure itself, undaunted, with the spirit of arbitrary rule of which that engrossing and tyrannical house is the embodiment.' And the struggle for freedom, for civic life, was continued till in the 16th c. it developed into the greater struggle for religious liberty. On the death of Charles the Rash the N. fell (1477) to the Archduke Maximilian of Austria, who had married the duke's daughter Marie. During the reign of Karl V., son of Philipp the Handsome of Austria and Juana, a daughter of Ferdinand and Isabella of Spain, the industry and commerce of the N. developed rapidly in spite of oppression. The Reformation doctrine early found a home in the country, and Philip II., who succeeded his father Karl V. in 1555, made a determined effort to root it out. But the schemes of the Inquisition and the unparalleled tyranny of Philip stirred the people to a struggle which, inaugurated by the terrible atrocities of Alba, and lasting over eighty years (from 1566), ended in the humiliation of Spain and the firm establishment of the Republic of the United Provinces, or rather of a league of seven federal provinces, joined very loosely together, and governed by Stadtholders and 'Estates.' The southern provinces, nearly corresponding to modern Belgium, were secured to Spain and the Roman Catholic Church by the consummate abilities of Parma. Philip III. was obliged to conclude a thirteen years' truce, the Peace of Antwerp, in 1609, and the independence of the United Provinces was recognised by all the European powers long before Spain gave its tardy concurrence, at the close of the Thirty Years' War, by the Peace of Münster, 1648. William the Silent, Prince of Orange, was the 'father' of the Republic, and the story of its rise is at the same time his biography; with his death may be said to close the heroic period in Dutch history. Head and ruler of the state in a sense that is true of but few kings, and invited to assume the crown by all the municipalities save that of Amsterdam, William was never actually invested with sovereignty. Olden-Barneveld subsequently pressed the claims of Maurice to the crown, but as he rose in power, the Advocate himself became the rival of his prince. Meantime the little commonwealth had become the greatest existing naval and commercial power, girdling the world with its innumerable dependencies. It had nearly one hundred thousand sailors and three thousand ships, and for a century longer it was absolutely master of the seas. From 1610 till 1619 a fierce struggle raged between

Arminians and Gomarists, distracting the country and leading eventually to the execution of Barneveld. The stadtholder, William II., married Mary, eldest daughter of Charles I. of England, and after the thrill of horror with which the news of that king's execution was received throughout Europe, Holland took the lead in acts of open hostility. The 'Dutch War' of 1652-53 was signalled by the first defeat which Holland, since the downfall of Spain, had sustained upon the sea. After a fierce encounter in the Channel, Blake forced De Ruyter to retire under cover of night; but the fleet was at once raised to seventy-three ships, and with this force, double that of the English, the veteran Van Tromp drove Blake into the Thames, and swept the Channel in triumph with a broom at his mast-head. This struggle, which the wisdom of Cromwell had closed, was renewed in 1664, ostensibly to settle the monopoly of trade on the Guinea coast, but really on account of the ambition of the Duke of York, and the resentment of Charles at the insults he had suffered from Holland in his exile. Monk twice defeated De Ruyter, and sailed along the coast of Holland, burning ships and towns. But the Dutch found a powerful and unexpected ally in the Plague which fell on London (1666), paralyzing the energies of the nation. The treasury was empty, and neither ships nor forts were manned when the Dutch appeared in the Nore, advanced unopposed up the Thames to Gravesend, burst the boom on the Medway, burned three men-of-war which lay anchored in the river, and for six weeks sailed defiantly along the southern coast, undisputed masters of the Channel. William III., who had been excluded from the stadtholdership by the jealousy of Oliver Cromwell and the action of the republican party in Holland, was, on the murder of the brothers De Witt (q. v.), restored in time to save his country from the rapacity of France. Louis XIV. (q. v.) in two campaigns attempted the conquest of Holland, and had secured the non-intervention of the Emperor. His first invasion of the Low Countries was checked by the Triple Alliance between England, Holland, and Sweden (1668), binding him to the terms he had offered as a blind, and forcing on him the Peace of Aix-la-Chapelle. In 1672 war was declared against Holland by France and England, Louis having detached Sweden and easily procured the aid of Charles. But after meeting with a desperate resistance Louis was forced to forego his designs by concluding the Peace of Nimwegen in 1678. William III., who had married Mary, eldest daughter of James II., and was now the head of a European league against Louis, became King of England in 1689, and as such continued the struggle with France. During the American Revolution the N. declared war against England, jealous of her growing maritime power, but in 1782 a final blow was given her naval supremacy. After several years of civil strife, the rights of the House of Orange were confirmed and enlarged in 1789. Two parties had long been conspicuous in the state, the one anxious to raise the stadtholders to the dignity of kings and make the office hereditary in the family of Orange-Nassau, the other, the 'patriots,' striving to establish a pure republic. When in 1794 a French army entered the N. after conquering the Spanish N., it was hailed by the patriots; the stadtholder, William V., fled to England, and the Batavian Republic was proclaimed 16th May 1795. It was made a kingdom by Napoleon I. for his brother Louis in 1806, and a department of France in 1810. Holland was united to Belgium from 1813 till 1830, when the latter became an independent monarchy. After the treaty of London (1839), which settled the differences between Holland and Belgium, and adjudged an equitable partition of Luxemburg (q. v.), the chief events in the external history of the N. are the abolition of slavery in the Dutch W. Indies (1863), the cession of the Gold Coast settlements to Great Britain in 1871, and the tedious and costly war in Atchin (q. v.) begun in 1873 and not yet (1878) ended. Meantime a great political struggle has been going on in the country, chiefly to decide whether unsectarian education shall continue. The 'liberal' party in the state are generally regarded as having secured a final triumph by the elections of December 1877. See the article BELGIUM, and Bilderdijk, *Geschiedenis des Vaderlands* (12 vols. Leyden, 1832-39); Motley's *Rise of the Dutch Republic* (3 vols. Lond. 1856-59); and *History of the United Netherlands* (4 vols. 1860-67).

Netley, Royal Victoria Hospital, at, is a palatial building on the shore of Southampton Water, which was com-

menced in 1855, and erected at a cost of about £350,000. The hospital, which was designed for the reception of invalids from the army and navy on foreign service, and from among the troops in the adjoining military districts, was constructed on the most approved principles, so as not only to be efficient for the purposes intended, but a model hospital for the State. The hospital is also utilised as a medical school for candidates for the army and navy medical departments; and in it special facilities are afforded for practical instruction in those departments of medicine, surgery, and hygiene peculiar to military service. There is accommodation in the hospital for over 1000 patients. See MEDICAL DEPARTMENT OF THE NAVY.

Nettle (*Urtica*), a genus of about forty species of herbaceous or rarely shrubby plants, widespread in the tropical and temperate regions of the world, and giving name to the natural order *Urticaceae*. They have opposite leaves, monœcious or dioecious flowers in axillary clusters or spikes, and an achene as fruit. Many are covered with stinging hairs, the name *Urtica* (from Lat. *uro*, 'I burn') being chosen for the genus in allusion to the burning pain of the sting. These hair-stings are formed of a single conical cell dilated at its base, and closed at the apex by a globular button placed obliquely. The button breaks off on the slightest touch, when the sharp extremity of the hair enters the skin and pours into the wound the irritating fluid which has been pressed out from the elastic epidermal reservoir at the base. When the plant is grasped with violence the sting is crushed, and no injury is effected. Two species of N. are natives of Britain—the one, an annual, common in waste and uncultivated ground about dwellings, is the small N. (*U. urens*), and the other, or common N. (*U. dioica*), is the universally known plant of our roadsides and hedgebanks. Another species, called Roman N. (*U. pilulifera*), is occasionally found, but is in all likelihood an introduction. The young shoots of the common N. are commonly used as a pot-herb on the Continent of Europe, and occasionally also in this country; they are wholesome but have a disagreeable grittiness. A yellow colouring matter is obtainable by boiling the roots with alum, and from the stalks and leaves a green dye is procurable. Formerly, before the introduction of flax and hemp into the northern countries, a tough fibre obtained from the inner bark of this species was manufactured into cordage, a coarse cloth, &c., and the name N. indicates this fact. Westmacott in his *Scripture Herbal* (1694) says, 'Scotch cloth is only the housewifery of the N.' An infusion of the leaves is used in country places to purify the blood, and a mixture called N.-beer is made and sold in the large manufacturing towns of Lancashire and bordering counties. The stinging property of some of the Indian species is powerfully developed, especially in *U. stimulans* and *U. crenulata*. Both of these are, however, exceeded by *U. urentissima*, a plant of dreadful renown; its effects are so violent as to last for months or even a year. It is nearly equalled by two Australian species, viz., *U. morioides*, a bush, and *U. gigas* (or *Laportea gigas*), a large tree with heart-shaped leaves a foot or more in width, beset with hairs of an exceedingly virulent stinging power. Cattle coming in contact with it are made furious, and it is necessarily a great impediment to the traveller. Some of the nettles are used for medicinal purposes, as *U. baccifera* in the W. Indies and *U. membranacea* in Egypt, and the tubers of *U. tuberosa* are reported to serve as a food in India. In the Sandwich Islands the fibre from *U. argentea* is employed for making ropes, as is that of *U. baccifera* in the W. Indies, and *U. Cannabina* also yields a useful fibre. (See BOEHMERIA.) The name dead-N. is applied to the genus *Lamium* belonging to Labiata. It has no connection with the above, but the leaves of some of the species are N.-like in outline.

Nettle-Rash, or *Urticaria*, is an eruption of little, solid, elastic eminences, closely resembling that produced by the application of a common nettle to the skin. The wheals or raised patches have a white centre and red margin of irregular form, and are accompanied by more or less tingling and itching. N.-R. when acute runs a rapid course, and is accompanied with a smart fever; but when chronic, it is slow, obstinate, persistent, and has a tendency to recur. The acute forms are generally connected with the ingestion of some kinds of food, constituting errors of diet, as shell-fish, cucumbers, almonds, oatmeal cakes, &c. The more chronic and intermittent forms are frequently associated with uterine derangements of various kinds. *Treatment*—In the

acute form, an emetic followed by a purgative should be administered, and afterwards faulty digestion should be corrected. The diet should be simple, without wine, beer, or stimulants, and tepid baths should be used. The cutaneous irritation may be allayed by a lotion containing *prussic acid* and *perchloride of mercury*.

Nettle-Tree (*Celtis*), a genus of handsome trees belonging to the elm family (*Ulmaceæ*), but widely different from the elms by bearing a fleshy drupe or fruit. The common N.-T. (*C. Australis*) grows to 50 feet high, is ornamental, and in Europe is frequently planted in squares, along public walks, &c. The wood is hard and dense, eligible for turners' and carvers' work, also for musical instruments, and the elastic shoots or branches are in request for whip-stocks, walking sticks, &c. The small black fruit, after it has been touched by the frost, is edible and wholesome; it has a very sweet flavour, hence supposed by some to be the Lotus (q. v.) of the ancients. The tree is a native of the S. of Europe and coast of N. Africa. The hackberry, haggberry, or Hoop-Ash (q. v.) is a fine forest tree of Ohio, &c., called *C. crassifolia*. It grows to the height of 80 feet, and yields an elastic wood which is used for charcoal. The sweet fruits are edible. Of *C. orientalis*, the inner bark consists of numerous reticulated fibres forming a kind of natural cloth, used by some of the tribes of India, where the tree is pretty common, for clothing purposes and as a rug or blanket. *C. caucasia*, another Indian species, is a fine large tree, but the wood is light, soft, and subject to attacks of insects.

Neu-Bran'denburg, a town of Germany, grand-duchy of Mecklenburg-Strelitz, on Lake Tollens, 17 miles N.N.E. of New-Strelitz by rail. It has large breweries and distilleries, and manufactures paper, carls, &c. Near it is the fine ducal palace of Belvedere. Pop. (1875) 7495.

Neuburg, an old town of Bavaria, on the right bank of the Danube, 12 miles E. of Ingolstadt by rail. Its royal schloss, on a height, contains an interesting collection of portraits and armour. The ducal line of Pfalz-Neuburg expired in 1742. Pop. (1875) 7297.

Neuchwang, a port of China, in Manchuria, on the left bank of the river Liao, 25 miles from its mouth, and 110 miles S.W. of Mukden. Its trade is slowly developing in spite of the difficulty of transit and the prevalence of brigandage throughout Manchuria. In 1874 (a poor year comparatively) the total value of the imports and exports (less re-exports) was £1,256,003, and the number of vessels that entered and cleared the port was 512 of 181,084 tons, including 202 German vessels of 61,912 tons, 126 British of 49,934 tons, and 92 American of 31,574 tons. The imports are chiefly cotton and woollen goods, opium, sugar, and metals; the exports beans, bean-cake, bean-oil, barley, ginseng, other drugs, fungus, deer-horns, and melon-seeds. Pop. 30,000.

Neuchâtel, **Neuchâtel**, or **Neuenburg**, a western canton of Switzerland, lies between the lake of the same name and the French frontier. Area, 304 sq. miles; pop. (1870) 97,284. N. is traversed from N.E. to S.W. by four lateral ranges of the Jura, and watered by the small streams Reuse, Seyon, Serrierre, &c. The natural products are wheat, wine, timber, and fruits. N. rears cattle, sheep, horses, goats, swine, and bees. The Val de Travers is famous for its asphalt stone; and other minerals found in N. are coal and iron ore. But the great specialty of the canton is watchmaking, an industry introduced by J. Richard at La Sagne in 1681, and now producing yearly some 300,000 watches (value 20 million francs), of which 30,000 are exported to the United States. At La Chaux-de-Fonds and Le Locle, the great centres of the trade, are made many of the best watches sold at Geneva. Lace-making, though still an important industry, is on the decline. Among the exports are cheese, printed cottons, scientific instruments, paper, *bijouterie*, and *extraît d'absinthe* (170,000 bottles yearly). The inhabitants, mostly French Protestants, are distinguished for ingenuity and orderliness. The principality of N. formed part of Burgundy till it was united to the empire in the 11th c. In 1288 the emperor Rudolf of Hapsburg gave it to Jean Comte de Chalons, whose great-grandson Jean III. became by marriage Prince of Orange. On the extinction of the house of Orleans-Longueville in 1707, N. was adjudged by the estates to Friedrich I. of Prussia, who was chosen over other fourteen claimants on account of his descent from the Prince of Orange. It remained with Prussia till 1806, when

278

Napoleon conferred it on Marshal Berthier. It formally joined the Swiss Confederacy in 1815, and the bond with Prussia was finally dissolved by a treaty signed 26th May 1857.—**Lake Neuchâtel** belongs to the river basin of the Rhine, is 27 miles long and 6 broad. It is drained by the Aar, abounds in fish, and its shores in some parts exhibit bright and picturesque scenery.

Neuchâtel, capital of the Swiss canton of the same name, situated on a steep slope of the Jura, overlooking Lake N., at the entrance of the Seyon, 25 miles W. of Bern. It has a castle, the seat of the cantonal government, a Temple du Haut of the 12th c., a new college, containing a natural history collection founded by Professor Agassiz, a picture-gallery, chiefly of modern Swiss works, and many celebrated charities. There is an important trade, especially in watches, wine, grain, and cattle. Pop. (1870) 13,321.

Neuhaus, an old town of Bohemia near the Moravian frontier, and on the river Nescharka, has a grand castle of the Czerny family, and manufactures paper, chemicals, &c. Pop. (1867) 8620.

Neuhaus'el (*Ersek-Ujvár*), a town of Hungary, formerly a strong fortress, on the Neutra, 75 miles N.W. of Pesth by rail. It was conspicuous in the Turkish wars, but is now a dull market town. Pop. (1869) 9483.

Neully, a town of France, department of Seine, 1½ miles N.W. of Paris, on the right bank of the Seine, which is here spanned by a magnificent five-arched bridge, 640 feet long, erected by Perronet (1768-73). The château of N., destroyed in the revolution of '48, was a favourite residence of Louis-Philippe, and the spot where his son Ferdinand was killed in a carriage-accident (July 13, 1842) is marked by a Byzantine chapel, designed by Ary Scheffer. Bleaching, distilling, and nursery-gardening are the principal industries. Pop. (1872) 15,466. Being wholly within the French lines, N. came little into notice during the Prussian siege of Paris, but it was the scene of several engagements between the Communists and the Versailles troops, April 20-May 21, 1871.

Neumünster, a town of Prussia, province of Slesvig-Holstein, in a barren plain, on the Schwale, and near the Stör, 36 miles N. of Hamburg, at the junction of railway lines to Kiel, Neustadt, Hamburg, and Slesvig. N. manufactures cloth, carpets, linens, cottons, leather, and metal buttons. It derives its name from an Augustinian monastery, founded in 1130, and removed to Bordesholm in 1326. Pop. (1875) 8628.

Neuralgia. See NERVOUS SYSTEM, DISEASES OF.

Neuroptera (Gr. 'nerve-winged'), an order of Insects (q. v.) having long bodies. The wings are large, broad, and have prominent veins or *nerveures*. Many N. (e.g., dragon-flies) are of predatory habits, and pursue and devour other insects. The mandibles, or longer jaws, are well developed. The abdominal appendages do not form a 'sting,' but subserve egg-deposition. The N. as a rule undergo an imperfect *Metamorphosis* (q. v.), the chrysalis or *pupa* being active. But in some few cases the metamorphosis is complete; and in such cases the pupa may be enclosed in a cocoon. The young of N. are frequently aquatic in habits, and pass their earlier stages in pools and rivers, as is the case with the dragon-flies, May-flies, &c.

Neusatz (Ger. 'new settlement,' Magyar *Új-Vijádk*), a town of S. Hungary, in the comitat of Bács, on the left bank of the Danube (here crossed to Peterwardein by a fortified bridge of boats 847 feet long), 70 miles N.W. of Belgrad. It is the seat of a Greek bishop, and has ten churches, and an important trade in corn. N., founded in 1740, has been rebuilt since the Hungarian Revolution, during which it was taken, June 11, 1849, by the Imperial troops under Jellachich, and nearly destroyed by the insurgents' fire from Peterwardein. Pop. (1869) 19,119.

Neuse River, in North Carolina, U.S., is formed by the confluence of the Flat and Eno. It flows S.E., and enters Pamlico Sound, after a course of 300 miles, great part of which is navigable by steamers.

Neusiedler-See (Magyar *Fertő-tava*), a brackish lake in W. Hungary, 7½ miles W. of Oedenburg. In 1860 its area was 122½ sq. miles, and in 1862 its depth was still 2-3 feet, but in the beginning of the summer of 1865 it quite dried up, as it is said to have done also in 1693 and in 1738. The dry bottom was laid

401

out in farms, but in 1870 a great body of water returned from the Raab and Rabbitz through the Hanság ('floating turf') swamp (the draining of which had been commenced in 1865), covering 454½ sq. miles of arable and productive land.

Neu-sohl (Ger. 'new settlement,' Magyar *Beatercs-Bánya*), a town in Hungary, comitat of Sohl, at the confluence of the Gran and Bistritz, 23 miles N.N.E. of Schemnitz by rail. It is a Catholic bishop's see, and has the largest copper and iron mines in Hungary. Lead and coal are also worked, and beet-sugar, paper, and colours are manufactured. 4½ miles N. are the copper and silver mines of *Herrensgrund*. Pop. (1869) 11,780.

Neuss (the *Novesium* of the Romans), a town of Rhenish Prussia, on the Erft, 1 mile from the left bank of the Rhine, and 5 miles W.S.W. of Düsseldorf by rail. It has a fine Catholic church of St. Quirinus (1209), the chief corn-market in Rhenish Prussia, and the largest oil and flour mills in Germany. Cottons, woollens, linens, machinery, hardware, soap, and brandy, are among the manufactures. Pop. (1875) 15,563.

Neustadt ('New Town'), a very common name of German towns. The following are the most important:—1. **N.** (Polish *Prudnik*), a town of Prussia, province of Schlesien, at the confluence of the Braune and Prudnicka, and on the Frankenstein-Kosel railway, 160 miles S.S.E. of Breslau. It has an excellent *Real-schule*, and considerable manufactures of damasks, linens, cottons, and silk. In the bombardment by the Austrians (28th February 1779) the greater part of the town was destroyed. Pop. (1875) 10,941.—2. **N.**, a town of Prussia, in the province of W. Prussen, on the river Biala and the Berlin-Stettin railway, 28 miles N.N.W. of Danzig. It has a castle, a gymnasium, and twenty chapels on the wooded heights S. of the town, annually visited by numerous pilgrims. Pop. (1875) 4,140.—3. **N.-Eberswalde**, a town of Prussia, province of Brandenburg, on the Finow Canal and the Berlin-Stettin railway, 28 miles N.E. of Berlin, has a school of forestry (founded 1824), and manufactures flour, nails, and deals. Pop. (1875) 8,223. Near N.-E. are the villages Spechthausen, with a government paper manufactory; Heegermühle, with the largest brass-foundry in Prussia; Eisenspaltelrei, with a great iron-foundry; and Kupferhammer, with iron and aniline manufactures.—4. **N. an der Orla**, a town of Central Germany, in the grand-duchy of Sachsen-Weimar-Eisenach, on the river Orla and the Gera-Eichicht railway, 30 miles S. of Naumburg, with a fine castle (Arnshaugk) and manufactures of cloth and leather. Pop. (1875) 4,816.—5. **N. an der Haardt**, a town of S. Germany, in Rhenish Bavaria, at the junction of the Pfalzgraf-Ludwig's and the N.-Monsheim railways, 18 miles S.W. of Mannheim. It has a fine Gothic church of 1346, a richly endowed hospital, manufactures of cloth, paper, furniture, starch, and straw-plait, and extensive trade in wine and fruit. Pop. (1875) 9,320.

Neu-Stettin, a town of Prussia, province of Pommern, lies between two lakes near the source of the river Persante, 92 miles E.N.E. of Stettin. It was founded in 1313, is built after the pattern of Stettin, and has manufactures of leather. Pop. (1875) 6,971.

Neu-Strelitz, the capital of Mecklenburg-Strelitz, lies between the lakes Zierker and Glambecker, 60 miles N.E. of Berlin by rail. It is laid out in the form of an eight-rayed star, and has a beautiful castle, the residence of the Grand Duke, containing a library of 80,000 vols., and surrounded by fine gardens. Alt-Strelitz (pop. 2,997), a mile to the S., was formerly the capital, and has a great horse market. Pop. (1875) 8,525.

Neustria (either *neueste rik*, 'the latest kingdom,' or *ne-oster rik*, 'the not-eastern,' i.e., 'the western kingdom'; Lat. *Francia Occidentalis*), the name under the Merwing and Karoling dynasties of the western kingdom of the Franks, which, extending from the Scheldt to the Loire, and bounded on the E. by the Maas, Vosges, and forest of Ardennes, included the two Flanders and ten of the later provinces of France, and had a total area of upwards of 60,000 sq. miles. Soissons, Paris, Orleans, and Tours were the chief towns. From the 10th c. onward, after Charles the Simple's concession of Normandy to Rolf the Ganger, the name N. disappears from history.

Neutitschölein (Czech *Nový Jičín*), a town of Moravia, Austria, in the district called Kuhländchen (Czech *Křavarska krajina*) or 'Cow-country,' 25 miles S. of Troppau by rail. It has three

churches, and manufactures woollens, leather, and a kind of Polish carriages, hence called *Neutitschöinky*. Pop. (1869) 8645.

Neutra or **Neitra** (Magyar *Nyitra*), a town of Hungary, in the comitat and on the river of the same name, 75 miles N.W. of Pesth by rail. On Mount Zobor, E. of the town, is a strong castle. M. is a Catholic bishop's see, has three monasteries, two cathedrals, and a theological college. There is considerable trade in wine. Pop. (1869) 10,683.

Neutral Tint, a pigment, artificially prepared by mixing together blue, red, and yellow in varying proportions.

Neutrals, the name given to nations who take no part in a war that is being carried on by other nations. Their duties have given rise to much controversy. See INTERNATIONAL LAW, BLOCKADE, CONTRABAND OF WAR, LETTERS OF MARQUE.

Neuwied, a town of Rhenish Prussia, on the right bank of the Rhine, 12 miles N.E. of Koblenz by rail. Its chief building is the castle of the Wied family, which contains a museum of Roman remains. There are manufactures of woollen and cotton fabrics, hosiery, leather, iron wares, and tobacco. Pop. (1875) 9,483, of whom 400 are Moravians.

Ne'va, an important river of Russia, flows from the S.W. corner of Lake Ladoga in a westerly direction to the Gulf of Finland, which it enters after passing in two main branches through the city of St. Petersburg. It is a broad, rapid stream, 40 miles long, but its entrance is shallow, and its immense trade is therefore mainly conducted by small steamers and lighters. By the Ladoga Canal it is connected with the water system of the Volga, and thus assists in uniting the Baltic and Caspian Seas.

Neva'da, one of the Pacific States of the American Union, is bounded N. by Oregon and Idaho, E. by Utah, and S. and W. by California. Area, 104,125 sq. miles; pop. (1875) 68,760, including 3152 Chinese, 1251 coloured people, and 16,220 Indians. Most of N., included in the 'Great American Basin,' is a table-land about 4000 feet above the sea, wedged in by the Sierra N. on the W. and by the Wah-satch Mountains on the E., and bounded N. and S. by cross ranges, thus having no outlet for its waters. Some 12,000 sq. miles of area, a romantic region of lofty mesas or table-lands and deep cañons, are outside this basin, and lie within the drainage of the Colorado River. Several of the peaks in the W. Humboldt and S. Toyabe ranges rise to a height of 12,000 feet, and the Sierra N. sends down many mountain streams, which disappear suddenly from the surface to reappear as lakes or pools. The lower valleys are frequently occupied by muddy pools, impassable on account of their depth in winter, and converted by summer heat into alkali flats crusted over with crude soda. Among the principal lakes are Pyramid Lake, 33 by 14 miles; Walker, nearly as large; Carson, 12 miles in diameter; Humboldt, slightly smaller; Winnemucca, 18 by 8 miles; and Tahoe, 6000 feet above the sea and 1500 feet deep. In 1874 the arable land amounted to 1,505,000 acres, the grazing land to 22,210,276, the timber land to 3,699,700, and the land on which minerals are wrought to 2,582,720. Everywhere throughout N. are visible evidences of volcanic action, the bleak mountain sides in many places being still covered with lava. Silver is the chief mineral, and is being produced in rapidly increasing quantity; the lodes which are found in every part of the state yield from \$65 to \$2500 per ton. Gold is found in considerable quantity in combination with silver. In 1874 there were 243 mines, and the yield of gold and silver amounted in value to \$35,402,263, of which \$22,000,000 came from the famous Comstock lodes at Gold Hill and Virginia. The Sutro Tunnel, already 3½ miles long, drains all the ramifications of the Comstock mines at a depth of 3000 feet, and is expected to be completed by January 1878. Besides gold and silver, N. also yields lead, copper, iron, antimony, arsenic, graphite, sulphur, lignite, &c. There are several geysers and many mineral springs. Although mining is the chief industry, many of the inhabitants are engaged in agriculture. The climate is somewhat rigorous and healthy. Summer brings the frequent thunderstorm, the violent whirlwind, and lofty dust columns. Among the wild animals are the grizzly bear, puma, lynx, antelope, deer, and sage-hare. The live stock in 1874 comprised 22,131 horses, 4732 mules and asses, 181,891 cattle, 185,486 sheep, 2439 Cashmere and Angora goats, and 5290 hogs. In 1876 N. contained 680 miles of rail-

way, the principal line being the Central Pacific. The capital is Carson city, and the largest town is Virginia (pop. 7048). N. is part of the territory ceded by Mexico in 1848, and was originally included in California. It was constituted a territory in 1861, and a state in 1866.

Nevers, a town of France, capital of the department of Nièvre, stands at the junction of the Nièvre and Loire, 112½ miles S.E. of Orleans by rail. Its chief buildings are the cathedral of St. Cyr (13th c.), the Palais de Justice, formerly the château of the Dukes of N., and a triumphal arch, erected in 1746 at the entrance of a seventeen-arched bridge across the Loire to commemorate the victory of Fontenoy. There are also the Hôtel-de-Ville, containing the Musée Nivernais, and a museum, public library, theatre, lyceum, &c. M. has six porcelain factories, employing 700 labourers; the largest ordnance foundry in France, turning out yearly 400 naval cannons; and manufactures of files, farm implements, chemicals, &c. Pop. (1872) 19,314. The *Noviodunum* of Cæsar, N., afterwards called *Nevirnum* and *Nivernum* (whence the modern name), was raised to a bishopric (506), and became the capital of the duchy of Nivernais (1538), which corresponded with the modern department of Nièvre. The duchy was purchased in 1659 by Cardinal Mazarin, whose last ducal descendant, Louis Jules Barton Mancini-Mazarini, died at Paris in 1798.

Neviansk, a town of Russia, government of Perm, on the eastern slope of the Urals, 45 miles N.N.W. of Ekaterinburg, has a mint, with a celebrated leaning-tower; and in the neighbourhood are extensive gold-washings, and iron-works which yield annually 4950 tons of iron. Estimated pop. 20,000.

Neville's Cross, Battle of, was fought near Durham, between the Scotch and English, October 17, 1346. In it the Scotch were totally defeated, their king, David Bruce (q. v.), made prisoner, and 15,000 of their nobles and commons slain. The English were commanded by the Archbishop of York, Henry Percy, and Ralph Neville, who raised the cross (destroyed in 1589), from which the battle takes its name. Froissart's statement that Queen Philippa was present in person is unsupported by any of the native chroniclers.

Nevis, one of the Leeward Islands, in the W. Indies, lies 2 miles S.E. of St. Christopher's, from which it is separated by the Narrows channel. Circular in form, it has a circumference of about 24 miles, and consists of a single conical mountain of volcanic origin 2500 feet in height. Area, 50 sq. miles; pop. (1871) 11,735. The revenue of N. in 1874 was £9786; expenditure, £11,150; public debt, £3000; value of total imports, £38,101; exports, £60,341, of which £54,079 was sugar. The total tonnage of British vessels that entered the port of Charlestown (the capital) was 15,198 tons, and of those that cleared, 11,148 tons. N. was first colonised by the English in 1628.

Nevis, Ben. See BEN NEVIS.

New Albany, a city of Indiana, U.S., on the Ohio River, 3 miles below Louisville, with which it is connected by rail. It has many fine buildings, 30 churches, 142 factories of various kinds, 3 newspapers, a large river trade, and splendid water-power from the falls of Ohio, 3 miles distant. Pop. (1870) 13,396.

Newark, a city of Ohio, U.S., situated on the Licking River, the Ohio and Erie Canal, 33 miles N.E. of Columbus by rail, lies in a rich agricultural district, near large coal-fields. It possesses two banks, several churches, and two newspapers, and, besides important manufactures, has a thriving trade in coal, grain, and live stock. Pop. (1870) 6698.

Newark-upon-Trent (the 'new wark' or 'fortress'), a market-town of England, in Nottinghamshire, 16 miles S.W. of Lincoln by rail, on the Devon, which joins the Trent both above and below the town. The chief buildings are the parish church, one of the largest in the kingdom (218 feet long by 80 broad, with a spire 245 feet high), the cornmarket (1849), townhall, and county court-house. There are large breweries and malthouses, iron and brass foundries, manufactures of boilers, farm implements, plaster of Paris, and a trade in malt, flour, corn, and cattle. N. returns two members to Parliament. At its castle, now in ruins, King John died (1216), and here Charles I. took refuge in the Scots' camp (May 5, 1646). Pop. (1871) 12,187.

New Bedford, a city of Massachusetts, U.S. on the Acushnet River, 55 miles S. of Boston. It was the chief port of the once flourishing whale fisheries of America, and now manufactures cottons, iron and copper wares, twist drills, Prussian blue, paraffin candles, glass, leather, &c. There are 2 daily and 2 weekly newspapers. Pop. (1870) 21,320.

Newberne, a city of N. Carolina, 90 miles from Hatteras Inlet, on the Atlantic and N. Carolina Railways. It has fifteen churches, two tobacco-factories, several lumber-mills and turpentine distilleries, and supports two daily and several weekly newspapers. It carries on a trade with the northern markets in early vegetables. Pop. (1870) 5849.

New Brighton, a town of New York, U.S., on Staten Island, and on the opposite side of New York Bay from Brighton. It has the largest dyeing and printing work in the U.S., a silk-printing factory, a paper-hanging factory, the 'Snug Harbour,' an institution for aged mariners, and another for sailors' destitute children. Pop. (1870) 7495.

New Britain, a large island in the S. Pacific, lying to the N.E. of the eastern extremity of New Guinea, and situated in 4°-6° 30' S. lat., 147° 40'-152° 25' E. longitude. It is 300 miles long, with an average breadth of 40 miles, and possesses several excellent harbours. It is mountainous, and still in a state of volcanic activity. The vegetation is luxuriant, and includes yams, the sugar-cane, ginger, bread-fruit, sago and cocoa-nut palms, &c. The inhabitants, who are Melanesians, are numerous, and though addicted to cannibalism, are said not to be fierce. Several Wesleyan mission stations were started on the island in 1876. N. B. is of interest as being the sole remaining habitat of the mooruk (*Casuarus Bennettii*), a large bird allied to the extinct *Dinornis* (q. v.).

New Britain, a city of Connecticut, U.S., 9 miles S.W. of Hartford by rail, manufactures iron, brass, and compressed bronze castings, cutlery, joiners' tools, white lead, hosiery, &c., and has a public park of 74 acres. Pop. (1870) 9480.

New Brunswick (so named in 1783 in honour of the house of Brunswick), a province of the Dominion of Canada, is bounded N. by the province of Quebec and Chaleurs Bay, E. by the Gulf of St. Lawrence and Northumberland Strait, S. by the Bay of Fundy, and W. by the state of Maine. Area, 27,177 sq. miles; pop. (1871) 285,594. The coast-line is 410 miles in extent, exclusive of Miramichi Bay, Richibucto Harbour, and other indentations. N. B. is watered by the St. John (450 miles), Restigouche (200), Petitcadillac (100), Miramichi (200), and other rivers; and has numerous lakes, the larger of which cover an area of some 80 sq. miles. The surface, generally a flat sandstone plain, nowhere exceeds 800 feet of elevation, and is densely wooded by forests of pine, fir, cedar, larch, birch, maple, &c. Seven-ninths of the entire area are set down as cultivable, and the estimated average yield per statute acre in 1871 was 10·8 bushels of wheat and 137·6 tons of potatoes. The thermometer in the shade ranged (1874) between 80° in September and 20° in January, and the rainfall in that year measured 34·2 inches. In the years 1868-75 N. B. exported 53,892 tons of coal; and iron, manganese, lead, copper, limestone, marble, &c., are also found. The forests abound in bears, wolves, deer, lynxes, and fur animals; the streams in trout and salmon; and the salt waters in cod, herring, mackerel, haddock, &c.; while grouse, wild fowl, and geese are plentiful. There were (1871) 163,687 horned cattle, and 234,418 sheep. The leading industries are agriculture, mining, the lumber trade, shipbuilding (in 1872, 108 vessels of 33,353 tons), the fisheries (in 1871 employing 5161 men, and yielding £237,000 worth of fish), and manufactures of sugar, woollens, oils, iron, leather, &c. In 1874 N. B. had 1147 vessels of 277,850 tons, and the total tonnage of vessels, to and from ports outside the Dominion was 1,574,903 tons; while the imports (grain, hardware, cottons, woollens, &c.) amounted (1875) to £2,131,382; the exports to £1,363,137, viz. timber, £948,391; fish, £93,061; sugar, £50,403; coal, £12,551, &c. The revenue, expenditure, and public debt are included in those of the Dominion. The provincial government consists of a lieutenant-governor and a council of nine; the legislature, of an Upper House of eighteen, and a Legislative Assembly of forty-one members; and N. B. sends twelve senators and twelve members to the Canadian Parliament. The active militia comprises 56

corps of cavalry, artillery, infantry, and rifles, with a nominal strength of 3327 men; and the reserves number 59,923. There are 375 miles of railway within the province, of which 108 are worked by government; and the number of schools (1871) was 828; of newspapers (1873) 26. A large percentage of the inhabitants are of French descent, and these, with the Indians (1629 in 1874) are mostly Catholics. There are two Catholic dioceses, St. John and Chatham, served by 59 priests; and one Protestant, Fredericton, with 62 clergy. The chief towns are St. John, Portland, St. Andrew, Fredericton (the capital), and Woodstock. Discovered by Sebastian Cabot in 1498, N. B. from 1604 formed, with Nova Scotia (q. v.) and part of Maine, the French colony of Acadie. It was ceded to Britain (1713), divided from Nova Scotia and erected into a province (1784), its entire population then amounting to 11,457, and dates its prosperity from an Act of the English Parliament (1809) for the taxation of Baltic timber. It was united with Canada for imperial purposes, March 29, 1867.

New Brunswick, a city of New Jersey, on the S. bank of the Raritan River, 30 miles S.W. of New York city, with which it is connected by rail. The seat of Rutgers College, with a library of 12,000 vols., and of a theological seminary, both under the Reformed (Dutch) Church, N. has 16 churches, 2 daily and 2 weekly newspapers, and manufactures of India-rubber goods, paper-hangings, machinery, &c. Pop. (1870) 15,058.

Newburg, a city of New York, U.S., is on the W. bank of the Hudson River, 60 miles N. of New York City by rail. It has a public library, a free academy, twenty-two churches, two daily and three weekly newspapers. The manufacture of machinery is its chief industry. The theological seminary of the Associate Reformed Church is here. Pop. (1870) 17,014.

Newbury, a market-town of England, in Berkshire, on the Kennet, 17 miles W.S.W. of Reading by rail, has three churches, a corn-exchange (1860), town-hall, theatre, &c. There are silk and paper-mills, and a trade in corn and malt. Here lived the famous 'Jack of N.', who led 100 of his weavers to the Field of Flodden. Doddington Castle, in the neighbourhood, belonged to Chaucer. In the indecisive battle of N. (1643) fell the gallant Falkland (q. v.), to whom a monument has been erected (1877) in the market-place. A second battle (1644) was a victory for the Parliamentary forces. Pop. (1871) 6602.

Newburyport, a city of Massachusetts, U.S., 35 miles N.E. of Boston by rail, contains the University of Modern Languages, the Putnam Free School, a public library and free reading-room, five cotton-mills, eight shoe-manufactories, and four shipbuilding yards. In 1874 its annual imports amounted to \$227,353, its exports to \$39,076. Pop. (1870) 12,595.

New Caledonia, a large island in the South Pacific Ocean, lying between 20°-22° 30' S. lat., and 164° 10'-167° 33' E. long., 750 miles E. of Queensland. It was discovered by Captain Cook in 1772, and in 1854 was taken possession of by France. The island is now 200 miles long, and 30 wide, but the coral reefs which gird its shores show that it was once much larger. These reefs extend beyond the land 50 miles to the N., and 50 miles to the S., and in many places to a distance of 30 miles from the shore. They are most continuous on the W. or leeward side of the island. N. C. is composed of metamorphic rocks, and is traversed longitudinally by a triple range of mountains, varying from 2000 to 7000 feet in height. The soil is fertile, and well-adapted to the growth of tropical produce. N. C. is believed to be rich in minerals, but as yet the deposits of nickel alone are worked, upwards of 1000 tons being exported in 1877. The mines are chiefly worked by Victorian capital. The natives of N. C. belong to the Melanesian race, and are ferocious cannibals, whom the Roman Catholic missionaries have had little success in improving. Their number is estimated at 30,000. For some years N. C. has been used as a French penal settlement, and on the 1st January 1876 there were 3575 convicts in the island. Since 1872 many Communist prisoners have been transported to N. C., but are confined on the Isle of Pines, 28 miles to the S.E. Noumea is the chief town of N. C., and the seat of government.

Newcastle, a town in New South Wales, at the mouth of the Hunter river, and 75 miles N. of Sydney. It is the shipping port of an extensive coalfield which has been worked for 33 years, and the coal from which is exported to all parts of the Australian

colonies, as well as to India, China, Japan, the Sandwich Islands, and the Pacific ports of North and South America, the annual export exceeding a million tons. The coal seams, which are in close proximity to the town, are worked with less danger than in Great Britain, explosions of fire-damp being almost entirely unknown. The harbour is safe and commodious, but rather difficult to enter. The town, which is the see of a bishop, is well built and laid out. Pop. (1875) of the municipality, 7600; with the seamen on board the vessels in harbour, probably 10,000.

Newcastle, Thomas Pelham Holles, Duke of, the eldest son of Lord Pelham of Loughton, was born 21st July 1694. When only a boy he was adopted by his uncle, John Holles, Duke of N. and Earl of Clare. In 1714 George I. made him Viscount Pelham, and Earl of Clare, in 1715 Marquis of Clare and Duke of N. He served continuously under Walpole, whom he betrayed, and the broad-bottomed administration of Pulteney, from which he and his brother Henry Pelham excluded Carteret. In 1754 he became Premier, his brother having just died. In this capacity he yielded up Admiral Byng to the public clamour against him. He remained the nominal chief of Pitt, to whom his great connections and inexplicable popularity in both the Houses were necessary, but deserted him at a critical moment in the Seven Years' War, when the jealousy of the Whig party had grown too strong. On the formation of the Bute Ministry he retired, and after this only held the Privy Seal for a short time in the Rockingham administration. He died 17th Nov. 1768. His most conspicuous vices were flattery and jealousy. He was marked by a childish fussiness of character, and was entirely destitute of ability, except in the pricing of members and seats according to the corrupt system of Walpole. As Horace Walpole said, 'Mr. Pitt does everything, and the Duke gives everything.' He was succeeded by his nephew **Henry Fiennes Clinton**, ninth Earl of Lincoln, whose career was unimportant. His son, **Henry Pelham Fiennes Pelham Clinton, Duke of N.**, born 30th Jan. 1785, succeeded to the dukedom at the age of ten, was in France with his mother when the Peace of Amiens was broken, and was kept a prisoner by Napoleon till 1807. This appears to have made him a fanatical Tory for life. He was particularly odious to the English people about the time of the first Reform Bill, and subsequently withdrew in disgust from the discharge of his public duties as a hereditary legislator. He died 12th January 1851.—**Henry Pelham Fiennes Pelham Clinton, fifth Duke of N.**, was born 22d May 1811. At the Oxford 'Union' he met Gladstone and Herbert. Returned, when Lord Lincoln, in 1832 for South Notts, he was for a few months in 1834 a Lord of the Treasury under Peel. In opposition he spoke frequently and well on home affairs, and in 1841 Peel, to whom he was strongly attached, gave him the 'Woods and Forests,' and in 1846 the Chief Secretaryship for Ireland, in which capacity he had charge of the Irish Coercion Bill. As he had become 'unsound' on Protection, his father turned him out of South Notts, but he was returned by the Falkirk Burghs. In 1851 N. passed to the Upper House, and in 1853 was chosen along with other Peelites for the Aberdeen Coalition Ministry, of which he became Colonial Secretary. On the beginning of the Crimean War he devoted himself night and day to the War Department. The old military administration broke down under the unusual strain, and N., who along with his friend Herbert, was accused of both incapacity and indifference, resigned office in a memorable and pathetic speech in session 1855. His successor Lord Panmure testified to the energy with which he had done his best. From 1859 to 18th April 1864 N. was Colonial Secretary of the Second Coalition Government. He visited Canada and the United States with the Prince of Wales, and was enthusiastically received by the Orange lodges. He died 18th October 1867. The family of Clinton is said to be the oldest represented in the House of Lords except those of Berkeley and Neville.

Newcastle-under-Lyme (i.e., under the lime or border of the county-palatine of Cheshire), a market town of England, in Staffordshire, 40 miles S. of Manchester by rail, contains two churches, a guildhall, theatre, grammar school (1602), and a literary institute. There are twenty-seven factories (sugar refineries, silk and cotton mills, potteries, pipe works, tanneries, &c.), and a trade in corn, flour, and the coal and iron of the surrounding district. The hat manufacture has declined. N. returns two members to Parliament. Pop. (1871) 15,948.

Newcastle-upon-Tyne, the chief town of Northumberland, on the N. bank of the Tyne, opposite Gateshead, and in the centre of the largest coalfield in England, 15 miles N. of Durham, 275 N. of London, and 120 S.E. of Edinburgh, on the N.-Eastern Railway. North Shields and Blythnook are its suburbs, and the river, some 20 feet deep at ebb-tide, is here crossed by the famous High Level Bridge, by the Redheugh Suspension Bridge, and by a swing bridge. The first of these structures, one of the engineering triumphs of Robert Stephenson, dates from 1846-50, and comprises a broad carriage-way, passenger-paths, and above these a railway-level with three lines of rails. Supported by six massive stone piers, 125 feet apart, it spans the river by an equal number of arches of open iron-work. Its extreme length is 1375 feet, and the upper bridge is 112 feet above high water. The Redheugh Bridge (1871) crosses the river some distance above the High Level, and has a height of 92 feet above high-water mark, and a span of 345. The swing bridge, one of the largest of the kind in the world, was constructed in 1873-75 by Sir W. Armstrong, to replace the old Tyne Bridge of 1781, but immediately on its completion was greatly damaged by fire, and was only opened on 17th July 1876. Situated below the High Level, it is of special importance in allowing the free navigation of the river. The old part of the town skirts the river bank, which is lined by quays, and extends for some two miles. Narrow dingy streets wind up the steep bank to the platform on which the modern town is built. The houses here are in great part built of freestone, and among the principal thoroughfares are Grey, Clayton, and Grainger Streets. The chief extension of the town has been on the N. side, towards Brandling village in Jesmond Township. To the W. lies the suburb of Rye Hill, in the townships of Elswick and Westgate, while to the E. near the river is an extensive commercial district, occupied mainly by large stores and factories. At the top of Grey Street stands the Grey Monument, a lofty Ionic column, surmounted by a statue of Earl Grey, and erected in 1836. N. has 16 churches of the Establishment, 8 Presbyterian, 4 Roman Catholic, and several other churches. The mother-church of St. Nicholas (1359, restored 1877), is a grand cruciform structure, partly in Decorated, partly in Perpendicular style, with a fine pointed tower 194 feet high, a spired lantern, and peal of eight bells, and contains an altar-piece by Tintoretto, and many old tombs of the Percys. Among the chief secular buildings are the town-hall (completed 1858), comprising a council chamber, a corn exchange, a music hall seated for 2500 persons, municipal offices, &c.; a new county court-house (1865) in Ornate Italian style; the Moot Hall (1810) or old court-house; the Central Exchange, remodelled in 1867; the Old Exchange and Guildhall (1658, restored 1809), a spacious edifice with a steeple; the Central Station (opened 1850), where all the railways entering N. terminate; the Police station and courts, completed in 1873; the Post-office, built 1873-77; the Tyne Theatre (1867), seated for nearly 3000 persons; and the Royal Theatre. The improvements in the town are in great part due to the enterprise of Richard Grainger (died 1861), a builder of humble origin, who in five years is estimated to have constructed buildings of a rental of one million sterling. N. has an infirmary, two orphanages, asylums for the blind, the deaf and dumb, &c.; also an institute of mining, a college of medicine, and a college of physical science, established in 1871 in connection with Durham University. To the N.W. of the town are extensive barracks. To the N. are the Town Moor and Leazes, 1200 acres in extent, on which is the Hotspur Round, where races (including that for the Northumberland Plate), take place in June, and a public park, opened in 1873. The general market is one of the largest buildings of the kind in Great Britain, covering an area of nearly two acres. An important cattle market is held, to which in 1873 were brought 81,635 fat cattle, 350,638 sheep and lambs, and 39,585 swine. In 1876 there entered the Tyne ports 16,696 vessels of 5,154,362 (6667 steam of 3,217,412 tons) and cleared 17,133 of 5,455,213 tons (6980 steam of 3,445,330 tons). In 1876 the coal, cinders, and patent fuel exported from N. alone amounted to 4,009,739 tons (value £2,210,963), while the quantities and values of other exports were, of alkali, 2,472,355 cwt. (£747,669); iron (pig, bar, bolt, and wire), 27,807 tons (£131,302); iron railroads, 2093 tons (£16,743); all other kinds of iron, 16,878 tons (£192,320); of unwrought steel, 4005 tons (£2402); of wrought and part wrought steel, 83,354 tons (£342,870); of unwrought copper, 83,354 cwt. (£1864); of lead and lead ore, 235 tons (£197,483); of machinery,

£94,494; of arms and ammunition, £58,317 (including 60,000 lbs. of gunpowder); of chemicals, £48,655; of cotton yarn, £14,951; of cotton piece-goods, £29,949; earthen and china-ware, £21,506; of glass, £24,108; and of painters' colours, £92,517. The total value of exports (1876) was £4,625,658, and of imports (foreign and colonial) £5,631,082. There are extensive manufactures of steam-engines, iron bridges, and ordnance (at the Elswick Works of Sir W. Armstrong), of soda, bleaching-powder, vitriol, and other chemical products, of stained, plate, crown, and flint glass and bottles, of sheet lead, lead pipes, and shot, litharge, red and white lead, of paper, pottery, hemp and wire ropes, Portland and other cements (11,000 tons yearly), and especially of fire-bricks. The making of fire-bricks is a recent industry, and no fewer than eighty millions of these bricks are produced annually. In 1876 (a bad year) there were launched at N. 38 vessels of 25,861 tons, and of these only 3 of 57 tons were of wood; at the Tyne Ports (*i.e.*, at N. and North and South Shields) the launches were 75 of 27,551 tons, all iron except 15 of 205 tons. The N. quarries send forth some 100,000 grindstones yearly. The atmosphere of N. is much obscured by smoke, and the general dulness is ten times intensified when the dense fogs of the North Sea come sweeping up the Tyne. N. sends two members to Parliament, and is governed by fourteen aldermen and forty-two councillors, of whom one is mayor. There are published here two daily and five weekly newspapers. Pop. (1872) 128,443, with Gateshead, 177,070. Where N. now stands, the Romans had a stationary camp, Pons Ælii, near the E. end of Hadrian's Wall. Many interesting remains of this period were found in 1810. During the Old English period the camp became a noted residence of monks, and took the name of Monkchester. A memorial of the time when pilgrims flocked hither to visit the holy well of Jesus' Mount (now Jesmond) is still preserved in the name of Pilgrim Street. From a stronghold built (about 1080) by Robert, eldest son of the Conqueror, the town took its modern name of 'New Castle.' The present castle was built by Henry II. between 1172 and 1177, and, though sadly dilapidated, is one of the best extant specimens of Norman military architecture. The first charter entitling the townspeople to dig coal was granted by Henry III. in 1239. During the Scottish wars of the Edwards, N. was the frequent rendezvous of the English forces. After the battle of Marston Moor it was besieged and taken by the Scotch (1644), and in 1745 it was occupied by Wade.

New College, Oxford, was founded in 1386 by William of Wykeham (q. v.), for a warden, seventy fellows and scholars, ten chaplains, three clerks, and sixteen choristers. By ordinances made in 1857, and amended in 1866 and 1871, there are thirty fellowships and forty scholarships, fourteen of the former and thirty of the latter being restricted to students of Winchester College of at least two years standing. All the scholarships are tenable for five years, and are of the annual value of £80 with tuition free. The hall of the N. C. was restored by Sir G. Scott (1866), and new buildings erected (1872). He is at present engaged on the restoration of the chapel, the largest in Oxford, with its windows of Flemish glass, noble organ, and exquisite cloisters. N. C. presents to 41 livings, and in 1876 had 151 members of Convocation, 130 undergraduates, and 379 members on the books.

New England, the name of the eastern portion of the U.S., comprising Maine, New Hampshire, Vermont, Massachusetts, Rhode Island, and Connecticut. Originally called North Virginia when granted by James I. to the Plymouth Company for colonisation in 1606, the region subsequently received its present name from Captain John Smith, who explored and made a map of the coast in 1714. The inhabitants, mostly of Puritan and Scottish descent, are known distinctively as Yankees, and are distinguished for quickness, adaptability, and enterprise.

New Forest, in the S.W. corner of Hampshire, is about 14 miles long from N. to S., by 16 wide. Of its 66,790 acres, 17,532 are (1877) enclosed plantations, the rest being open oak and beech woods, bog, heath, &c. The absence of underwood gives a parklike appearance to the N. F., which, watered by the Ex and Boldre, and commanding frequent glimpses of the Solent and Isle of Wight, is the most beautiful of all the English forests. Gipsies, squatters, and deer have disappeared, but not its peculiar breeds of swine and ponies. It forms part of the Crown demesnes, and is under the charge of a lord warden, two rangers,

four verderers, &c. Lyndhurst, the 'forest capital,' has a fine parish church (860), with a spire 130 feet high, and an altarpiece by F. Leighton. Pop. (1871) 1544. At Minstead, $2\frac{1}{2}$ miles to the N., is the stone that marks the scene of William Rufus' death. The sites of other villages that stood within the present area of the Forest prior to its afforestation by the Conqueror are indicated by such names as Hinton, Winsted, Tackbury, &c. See Gilpin's *Forest Scenery* (1791); Wise's *The N. F., its History and Scenery* (Lond. 1874), and *N. F. Handbook, Historical and Descriptive* (Lyndhurst, 1875).

Newfoundland (Fr. '*Terre-Neuve*'), a large island between the North Atlantic and the Gulf of St. Lawrence, 90 miles N.E. of Cape Breton Island, and 14 S.E. of Labrador, from which it is separated by the Strait of Belle Isle. Along with many adjacent islets and the coast of Labrador, it forms the British colony of N. The greatest length of the island from N. to S. is 335 miles, and from E. to W. 330 miles; area, 40,200 sq. miles; pop. of colony (1874) 161,386 (58,091 Roman Catholics, 50,683 Anglican Episcopalians, and 28,639 Wesleyans). The coastline, bold, rocky, and much indented by deep bays (of which Placentia Bay on the S. and Trinity Bay on the E. leave only an isthmus 4 miles wide between the peninsula of Avalon and the rest of N.), forms a rough triangle, the extreme points of which are Cape Bauld in the N., Cape Ray in the S.W., and Cape Race in the S.E. The other chief inlets on the E. and N. are Conception, Bonavista, Notre Dame, and White Bays; on the W., St. George's Bay; and on the S., Fortune Bay and St. Mary's Bay. The surface is generally rocky and uneven, rising in some places to 1000 feet. The rocks are metamorphic, and of Laurentian age, while the Cambrian, Huronian, Lower Silurian, Upper Silurian, and Devonian are occasionally found. There are numerous lakes (called 'ponds') and rivers, the largest of which, the River of Exploits, nearly bisects the island, and falls into the Bay of Notre Dame. The interior is little known, and largely consists of great marshy plains, covered with scrubby vegetation, resting on deep layers of peat, and frequented by herds of deer and moose. According to the latest survey, only 726 sq. miles of land (chiefly along the banks of streams) are available for settlements. The Cape Breton coal measures extend to the S.W. part of N. The other minerals found are iron, copper, nickel, gypsum, graphite, petroleum, and marble. Many parts of the interior are rich in pine and other timber. Most of the inhabitants are in the peninsula of Avalon, and on the E. and S. coasts. The climate is cold and bleak on the coast, but milder inland. At St. John's, the extremes of temperature in 1874 were 83° F. in July and 14° F. in March. Oats, potatoes, turnips, and hay are raised, but the chief employments are the fishing for cod and seal on the shores of N. or Labrador, the manufacture of oils, mining, and wood-cutting. In 1869 there were in N. 14,726 horned cattle and 23,044 sheep. N. comprises 11 electoral districts, besides the 'French Shore,' a narrow strip of coast on the W., N., and E. sides of the island, occupied by the French for the purpose of curing fish. The revenue (nearly all derived from customs duties) was in 1874 £185,634; expenditure, £198,920; public debt, £239,39. In the same year the total tonnage of vessels that entered and cleared the ports of N. (exclusive of coasting-trade) was 476,141 tons (British 466,209). In 1869, when the last census was taken, N. had 26 ports of entry, the entries at which numbered 1200; 673 of these were at St. John's, after which Harbour Grace, La Poile, Channel, English Harbour, and Burin had the largest number. In 1870, 196 vessels, averaging 100 tons each, and including 13 steamers, were employed in seal-hunting. Besides the 'Shore Fishery,' in which small vessels are employed, there is the extensive 'Bank Fishery' on a tract (S.E. of N.) about 600 miles by 200, over a plateau from 20 to 108 fathoms below the sea. In 1876 the exports of the United Kingdom to N. and the coast of Labrador amounted to £455,428, and the imports from N. (copper, 24,003 tons; fish, 202,900 cwts.; oil, 6308 tuns; and 344,285 skins and furs) to £699,077. The cod-fishery, commenced by the Portuguese and French in 1501-2, was claimed by the English, who seized the foreign vessels engaged in it (1585). James I. incorporated the N. Fishing Company in 1610. The fishery was prohibited to the United States in 1775, but was reopened to them by the Treaty of Washington, 7th January 1854.

N. was discovered (24th January 1497) by John Cabot, who called it *Prima Vista*, explored by Jacques Cartier in 1534,

and taken possession of by Sir Humphrey Gilbert for Queen Elizabeth, 5th August 1583. Colonies were settled by Sir George Calvert in 1621, Lord Falkland in 1633, Sir David Kerik in 1654. In 1708 the colonists were partly conquered by the French, but the Treaty of Utrecht (1713) confirmed to England the possession of N., to which Anticosti and the coast of Labrador were annexed in 1809. The first governor was appointed in 1729. The present constitution, granted in 1832, consists of a governor and council exercising both legislative and executive functions, appointed by the Crown, and a House of Assembly elected by the people. See Pedley's *History of N.* (Lond. 1863).

Newfoundland Dog, is so named from having originally been brought from Newfoundland. It is allied to the Spaniel, and is notable for its love of the water and its swimming powers. There appear to be two varieties of the N. D. One is named the Labrador Dog, or St. John's N. D. It is smaller than the other, which has received the name simply of 'N. D.' The Labrador variety attains an average height of 23 or 24 inches, and its colour is darker than that of the other breed, in the coat of which black and white hues are boldly marked. The legs and feet of the N. D. are strong and broad, and the web between the toes is larger than that seen in other dogs. The N. D. is exceedingly intelligent. It may be trained to fetch and carry objects, and to seek with success for lost articles. Not its least notable characteristic is its devotion to man in danger, and its ability to save life in cases of shipwreck and disaster at sea. In Newfoundland the dog is employed as a beast of burden.

Newgate, a famous gaol in London, at the W. end of Newgate Street, opposite the Old Bailey. As early as 1218 it stood at the *new gate* of the city of London, of which it is still the chief criminal prison. It was rebuilt by the executors of Sir Richard Whittington probably about 1430, and was destroyed in the great fire of 1666, but was soon afterwards again rebuilt. In the year 1779, when N. was taken down and rebuilt a third time, it had become a hotbed of noisome pestilence, but from that date the utmost care has been taken to ensure cleanliness. The *Newgate Calendar* contains a remarkable collection of lives of noted criminals who have been confined in N.

New Granada. See UNITED STATES OF COLOMBIA.

New Guinea, or **Papua**, is next to Australia the largest island in the world. It is situated in 0° 30'—10° 44' S. lat., 131° 20'—150° 25' E. long., and has a length from N.W. to S.E. of nearly 1300 miles. Its breadth is very variable, the western portion being nearly insulated by Geelvink Bay and M'Clure Inlet, which approach within 17 miles of each other, while near its centre N. G. is fully 350 miles wide. The eastern extremity consists of a narrow and mountainous peninsula.

The first European who is known to have visited N. G. was the Portuguese Jorge de Meneses, in 1526, who called the island *Pupua*, a word whose meaning is variously interpreted to refer to the frizzly hair or the dark colour of the inhabitants. In 1528 the Spaniard Alvaro de Saavedra sailed along the N. coast and called the island N. G., on account of the resemblance of the natives to African negroes. Ortiz de Retez, another Spaniard, also visited the N. coast in 1546, and in 1606 Torres skirted the S. coast and discovered the strait which bears his name. In 1676 the Dutch under Schouten and Le Maire had a disastrous encounter with the natives. Bougainville in 1768, Cook in 1774, and other subsequent explorers, sighted the coast but did not land. Flinders, however, landed in 1791. Subsequent explorations were made by the French under D'Urville, and in 1828 by the Dutch, who having acquired the rights of the Sultan of Tidore, now claimed all the island W. of 134° E. long., and made an abortive attempt at a settlement at Triton Bay. In 1845 a British expedition under Captains Blackwood and Owen Stanley surveyed part of the S. coast, and the latter officer continued till 1850 the survey of the southern shores of the eastern peninsula. In 1858 a second Dutch expedition explored the N.W. coast, and in the same year the Dutch boundary of annexation was extended to 140° 50' E. long., so as to include Humboldt Bay. In 1873 Captain Moresby, in H.M.S. *Basilisk*, continued the work of Captain Owen Stanley, and ascertained the true form of the E. extremity of the island. He found it to be fork-shaped, and to be skirted by an archipelago of small islands through which he discovered a passage to which he gave the name of China Strait, as it shortens by 300 miles the steam voyage between Australia and China. Important explorations

have also been carried on since 1871 by the Russian Dr. Miklucho Maclay, the Italians Dr. Beccari and Signor D'Alberty, the Rev. Messrs. Macfarlane and Lawes, of the London Missionary Society, and Mr. Octavius Stone. To these six gentlemen is due most of what is yet known regarding the interior of the island, which is still, however, for the most part a complete *terra incognita*, the N.W. peninsula alone having been fairly explored.

N. G. is a very mountainous country, and some of its peaks exceed in altitude any others in the Pacific. The N., N.W., and N.E. coasts are almost everywhere skirted by mountains, which rise in the Arfak range to 9520 feet. From the head of Geelvink Bay there extends eastward the Charles Louis range, which is snow-capped, and is believed to reach a height of fully 17,000 feet. Further explorations may prove the suspected connection of this chain with the Owen Stanley range in the S.E. peninsula, whose loftiest peak is 13,205 feet high, the average height of the range being 8000 feet. The N.E. coast consists of a succession of large bays, terminating in bold headlands, and bordered by steep mountains, while the sea is very deep. Traces of volcanic action have been found in N. G., but are apparently ancient. On the S. coast to the E. of Torres Strait there is a great curve known as the Great N. G. Bight. Its shores are flat and marshy, and are intersected by numberless fresh-water channels. All the S. coast is fringed by coral reefs and mud banks. The climate of N. G. being very humid, several of the rivers are of considerable size. The largest as yet known is the Fly, which discharges into the W. side of the Great Bight. It was ascended by Mr. Macfarlane in a small steam-vessel for 150 miles, and he thought the same vessel might have proceeded 100 miles farther up the river. The Baxter or Maikassa river, whose mouth is in 9° 8' S. lat., 142° 18' E. long., and is 2 miles wide, was ascended by Mr. Macfarlane for 91 miles, and was then 30 feet wide and 12 deep. On the N. coast the Ambemohi appears to be an important stream. All the rivers have bars at their mouths, and their navigation is frequently impeded by mud banks and fallen trees. No lakes have as yet been discovered in N. G.

The vegetation of N. G. is most luxuriant, the country being for the most part buried in dense forests, though these in some parts give place to expanses of rich grass, six feet high. Among the principal trees are the cocoa-nut, nutmeg, canary wood, candlenut, sago-palm, betel-nut, mango, and banana. The bread-fruit, yam, taro, sugar-cane, tobacco, and cotton are cultivated by the natives and thrive well, but none of them is indigenous. The forests are inhabited by a profusion of beautiful birds, of which a good many species are confined to N. G. Chief among them are the magnificent Birds of Paradise (q. v.), of which several species are found in the W. portion of the island. Fruit-eating pigeons, parrots, and lorries are very abundant, and the cassowary and mound-building turkey are also natives of N. G. The mammals are less numerous, and with the exception of two kinds of bat, a peculiar pig (*Sus Papuensis*), and two species of echidna, they are marsupials. They include kangaroos (both terrestrial and arboreal), opossums, and the cuscus, the last being a curious little animal which seems to unite in itself several of the characteristics of the opossums and sloths. Snakes are very plentiful, but appear to be less commonly poisonous than in Australia. A species of python attains a large size. Insects are most abundant, and most of the moths are very large and beautiful, while the ants and spiders are formidable. The coasts abound in fish, turtle, and bêche-de-mer, and the pearl oyster is plentiful in Torres Strait.

The inhabitants of N. G. belong to the Papuan or Melanesian race, which seems to occupy a position midway between the Polynesian race on the one hand, and the aborigines of Australia on the other. Their usual colour is a sooty-brown of various degrees of darkness, but never reaching black except in the natives of the Arfak Mountains, whom Mr. A. R. Wallace regards as the true indigenes of north-western N. G. Dr. Beccari has also established the existence of a race of Negritos, similar to those of the Philippine Islands; while the Mafor or Mevoor Papuans in the N.W. peninsula give unmistakable evidence of the admixture of Hindu blood. In eastern N. G. the Polynesian race has made numerous settlements. The true Papuan is about 5 ft. 5 in. in height, and muscular, but with thin legs and large feet. His hair is long and frizzled, but though it appears to grow in tufts, Signor D'Alberty has ascertained that it is equally distributed over the scalp. The brows are prominent, the nose large and arched, and the lips protuberant. Unlike the Malays, the Papuans are

very demonstrative, being fond of boisterous laughter and noisy discussions, in which men, women, and children all join. They are fierce and warlike, and commonly cannibals. The skulls and lower jaw-bones are kept as trophies, some tribes wearing the latter as ornaments, and others painting and otherwise decorating the skulls of their slain victims. The bow and arrow are in common use, except among the mixed eastern tribes, who use spears. The Papuans have but dim ideas on the subject of religion, though some of them believe in a future state and in the existence of spirits, especially evil ones. Circumcision is not practised, and polygamy is rare. The women do all the field work. The Papuan language is much harsher than the Malay, and is divided into numberless dialects. The Papuans live in houses measuring in some cases from 300 to 500 feet in length, and built on piles. Clothing is usually dispensed with, or at best is of the scantiest description, though Signor D'Alberty obtained in the interior some petticoats made of human hair. Ornaments are almost universally worn, the chief being bracelets and anklets of grass or plaited rattan, often decorated with shells, besides ear and nose-rings, and plumes of cassowary feathers. Mr. Lawes saw at Hood's Bay a young woman with 27 tortoiseshell ear-rings in each ear, and nose-rings besides. The N.W. tribes comb the hair into a fan shape with a wooden instrument, which also does duty as a fork. The Papuans make excellent pottery, while with their sharp stone axes they hew fine canoes out of the solid trunks of trees. They especially excel in carving, in which their proficiency is wonderful. In the S.E. some of their villages are regularly laid out in streets and squares, are kept scrupulously clean, and even have flower gardens. In the N.E. they practise a system of terrace culture with much skill and success. Mr. Wallace predicts the early extinction of the Papuan race if the tide of colonisation should be turned to N. G., on account of its warlike and independent character. An agitation was commenced in Australia in 1874 for the annexation by Great Britain of N. G. to the east of the Dutch boundary, but as yet the movement has been without result. At present the exports from the island are birds of paradise, sandal wood, massoy bark (the produce of *Cinnamomum kiamis*), tripang, tortoiseshell, and pearl shell, but with proper cultivation it might be made to yield almost every kind of tropical produce in abundance.

Rosenberg (The Hague, 1875); *Discoveries and Surveys in New Guinea and the D'Entrecasteaux Islands*, by Captain Moresby, R.N. (Lond. 1876), and a number of papers by different authors, in the *Leisure Hour* for 1874-75; *Geographical Magazine* (vol. iii. 1876); *Nature* (vols. xiv. and xv., 1876-77); and the *Journal of the Anthropological Institute of Great Britain and Ireland* (vol. vi. 1877).

New Hampshire, one of the New England or eastern States of the American Union, is bounded N. by Quebec, S. by Massachusetts, E. by Maine and the Atlantic Ocean, and W. by Vermont, from which it is separated by the Connecticut River. Area, 9280 sq. miles; pop. (1870) 318,300, of whom only 603 are coloured, including 23 Indians. The State, nearly triangular in outline, is 178 miles long from N. to S., and 90 miles broad at the base in the S., while in the N. it has only a breadth of 4 miles. The sea-coast of 28 miles is low-lying, and in parts marshy, but some thirty miles inland the surface becomes broken and picturesque. As a country of mountains and lakes, N. H. has been called the 'Switzerland of America.' It is traversed by the Appalachians, part of which range, known as the White Mountains, contains the highest peaks in the north-eastern States. Among the chief heights are Mounts Washington (6285 feet), Jefferson (5794), Adams (5714), Clay (5553), Monroe (5384), Madison (5365), and Franklin (4904). This highland region, intersected by many fertile valleys and romantic glens, is clad with rich forests of oak, pine, beech, sugar-maple, birch, and other trees, and in the S. the river-courses are traced with a heavy growth of chestnuts, elms, poplars, locusts, willows,

hickories, &c. Besides the Connecticut and Piscataqua, which respectively bound the State W. and S.E., the chief river is the Merrimack. Many lakes—the Winnipisogee, Squam, Ossipee, &c.—give variety and beauty to the scenery. The formation is mainly Eozoic, the surface rocks being granite, gneiss, mica, and quartz. Iron and graphite are extensively mined, and other minerals found are silver, copper, lead, zinc, tin, talc, manganese, sulphur, magnesia, 'Bath brick,' jasper, amethysts, and garnets. In 1874 N. H. produced 1,239,000 bushels of Indian corn (value \$1,387,680) 174,000 of wheat, 41,000 of rye, 1,033,000 of oats, 84,000 of barley, 86,000 of buckwheat, 3,400,000 of potatoes (\$2,006,000), 180,000 lbs. of tobacco, and 767,200 tons of hay (\$10,073,336). In 1875 the live-stock comprised 47,000 horses, 211,900 cattle, 242,400 sheep, and 37,000 swine—total value, \$14,107,542. The State contains (1876) 940 miles of railway, and publishes sixty-one newspapers and periodicals. Concord is the capital, Manchester, the largest city, and Portsmouth the only port of entry. Settled first in 1623 by colonists from Hampshire in England, the territory was for some time joined to Massachusetts. It received its present constitution in 1783, and ratified the constitution of the United States in 1788.

New Harmony, a village of Indiana, U.S., on the Wabash River, 23 miles N.W. of Gransville. It was settled by the 'Harmonists,' a German religious sect, in 1815, transferred to Robert Owen for a socialist experiment in 1824, and finally became the seat of a 'school of industry' founded by William Maclure. Success has attended none of these enterprises, and the village has only a pop. (1870) of 836.

Newhaven, a seaport of England, in the county of Sussex, stands at the mouth of the Ouse, 56½ miles S. of London by rail. It derives its chief importance from the mail-packets which ply twice daily to and from Dieppe. In 1876 there entered the port 908 vessels of 189,303 tons; and cleared, 745 of 148,043 tons. The principal imports in that year were wine (152,824 galls.), leather (326,379 lbs.), gloves (100,371 doz. pairs), silk manufactures (£5,378,285), cotton manufactures (£55,059), and chemicals (£42,213); exports, wool (2,565,055 lbs.), raw silk (285,539 lbs.), and tin (11,134 cwt.). The N. shipbuilding yard has turned out 10 vessels of 809 tons during the years 1872-76. Pop. (1871) 2549.

Newhaven, a Scotch fishing-village 2 miles N. of Edinburgh, has a pop. (1871) of 1721. Its fishers and fishwives form a distinct community, rarely intermarrying with any other class, and have been depicted by Charles Reade in his *Christie Johnson* (Lond. 1853).

New Haven, the largest city in Connecticut, U.S., on a sandy plain at the head of a shallow harbour opening on Long Island Sound, and around the mouths of Mill, West, and Quinnipiack rivers, 76 miles E.N.E. of New York, with which it is connected by rail and by lines of steamers. A beautifully built city, it is the seat of Yale College (q. v.), and has 40 churches, a splendid city hall, many broad, elm-shaded streets, and important manufactures of rifles, iron-ware, carriages, &c. A new bridge over the Quinnipiack is (1876) being erected at a cost of \$136,000. There is a considerable foreign trade. N. H. was settled by Theoph. Eaton, the Rev. J. Davenport, and their followers in 1638. It was made joint capital with Hartford by the charter of 1662 and so continued,—the legislature meeting alternately in each place,—till 1873, when the latter became the sole seat of government. Pop. (1875) 55,667.

New Hebrides, a group of islands in the South Pacific Ocean, lying between 14°-20° S. lat., and 166°-170° E. long. The area of the group is about 2500 sq. miles, and the principal islands are Espiritu Santo (160 miles in circumference), Mallicolo, Vati, Erromanga, Api, Ambrym, Tanna, and Aneiteum. The N. H. are volcanic, and consequently their shores are nearly free from coral. Ambrym and Tanna contain large active volcanoes. The islands are very fertile, and produce yams, cotton, maize, bananas, and sandal-wood. A tiny species of pig, no larger than a rabbit, is the only native quadruped. The natives, who are very ferocious and degraded, belong principally to the Melanesian race, but there are Polynesian settlements on some of the islands. The two races do not amalgamate, and the number of dialects spoken in the group is marvellous. Missionaries from various societies in Great Britain, the Australasian colonies, and North America, have long laboured in the islands,

and a translation of the Bible in the dialect of Aneiteum is now (1877) in the press. Erromanga was the scene of the murder of the eminent missionary, the Rev. John Williams, in 1839, and of the Rev. Mr. Gordon and his wife in 1860. The present pop. of the group is probably not more than 20,000, one-third of the inhabitants having been carried off by an epidemic of measles in 1876.

New Holl'and, the former name of Australia (q. v.).

New Inn Hall, Oxford, formerly known as Trilleck's Inn, from its belonging to John Trilleck, Bishop of Hereford (1334), during the Civil War served as the royal mint (1642-46), and was restored to its academic purposes by Dr. Cramer, the late principal (1831-34). A chapel was added in 1868. In 1876 N. I. H. had 12 members of Convocation, 15 undergraduates, and 39 members in its books.

New Ireland, an island in the South Pacific Ocean, situated in 2° 35'-5° S. lat., 150° 30'-152° 45' E. long., and separated from New Britain (q. v.) by St. George's Channel. Its length is about 200 miles, and its breadth 12 miles on an average, though only one mile in some places. N. I. is hilly and covered with dense vegetation, while its shores abound with turtles and fish. The natives belong to the Melanesian race, and, like those of most of the adjoining groups, are cannibals. The women of N. I., however, unlike those of New Britain, are partially clothed, and seem to occupy a higher social position.

New Jersey, one of the original States of the American Union, is bounded N. by New York, S. by Delaware Bay, W. by the Delaware River, which separates it from Delaware and Pennsylvania, and E. by the Hudson River, Staten Island Sound, Raritan Bay and the Atlantic. Area, 7656 sq. miles; pop. (1875) 1,015,370, including a few Indians, Chinese, and Japanese. Its length from the extreme N. to Cape May in the S. is 170 miles, its greatest breadth 59 miles, and its least 32 miles. The coastline, including the bays, is 540 miles long, and is bordered to the extent of 295,474 acres by tide-marshes, much of which by ditching and banking has been rendered productive. In the N. the State is traversed by ranges of the Appalachians, the chief heights being Rutherford's Hill or Hamburg Mountain, 1488 feet, and Wawayanda Mountain, 1450 feet, near the New York boundary. Schooley's Mountain and the Musconetong Mountain are favourite summer resorts. The southern half of N. J. is a great plain, the surface of which is broken only by a few low hills, and in some parts eroded to a considerable depth by the streams. The State is watered by the Passaic, Hackensack, and Raritan, as well as by the boundary rivers Hudson and Delaware. With the exception of the Carboniferous, Permian, and Jurassic, all the geological formations are represented in the rocks and soils. A Triassic belt crosses the State from N.E. to S.W., and comprises Red Sandstone, with eruptions of trap, as best seen in the famous Palisades, a perpendicular ridge 200-500 feet high, extending along the W. bank of the Hudson for 15 miles. N. J. is rich in minerals. In 1874 there were 214 large mines of magnetic iron ores, and 12 of hæmatite iron ores, while bog iron ores are found all over the State in the wet meadows and swamps. The yield of iron ore in 1874 amounted to 525,075 tons. Clay, pure and shell marls abound, and are used as manure to the extent of 200,000 tons yearly, having already rendered the farming lands of N. J. of a higher average value than those of any other State. Among the other minerals are zinc, lead, potter's clay, glass, sand, roofing and writing slates, hydraulic lime, and Potsdam sandstone. The soil is mainly a slight sandy loam, but the surface has been converted into a garden, chiefly by the industry of German settlers. The mountain region of the N. has great forests of oak, hickory, chestnut, hornbeam, tulip trees, sassafras, &c.; in the S. there are pine tracts, with some cedars in the swamps. In 1874 the produce of Indian corn was 9,397,000 bushels (value \$7,705,540); of wheat, 1,986,000 (\$2,581,000); of rye, 480,000; of oats, 3,284,000; of buckwheat, 267,000; of barley, 7300; of potatoes, 2,919,000 (\$2,276,820); and of hay, 520,300 tons (\$8,439,266). The fruit crops are also very valuable. In 1875 the live-stock comprised 115,700 horses, 15,000 mules, 986,900 cattle, 127,100 sheep, and 164,600 swine—total value, \$28,500,000. N. J. ranks seventh in the list of manufacturing States. Within the State there are (1876) 1601 miles of railway. Of all kinds of newspapers there are 122. Trenton is the capital, and the largest cities are Newark, Jersey City, and Paterson. The earliest settlements seem to have been made by

Dutch traders in 1620. The whole territory was taken from the Dutch by an English force sent by Charles II. in 1664. It was subsequently given to Lord Carteret, then governor of Jersey Island, and hence received its name of *N. J.* Recovered along with New York by the Dutch for a short time in 1674, it was eventually sold to Penn and his associates in 1682, and became a refuge for the persecuted Quakers. During the War of Independence N. J. suffered severely from the incursion of British troops, and was the scene of the battles of Trenton, Princeton, Millstone, Monmouth, and Red Bank. Its constitution of 1776 allowed universal suffrage, but in 1807 women were deprived of their votes owing to the disclosure of certain corrupt practices.

New Jersey College, founded under the auspices of the Presbyterian Synod of New York, was chartered by New Jersey in 1746, and opened in Elizabethtown in the following year. It was removed to Newark in 1748, and finally to Princeton in 1757. The Rev. Dr. James M'Cosh, elected president in 1868, has greatly advanced the interests of the college. In 1875 it had sixteen professors, four other instructors, and 483 students, endowments to the amount of \$600,000, libraries comprising 44,000 volumes, various museums, and observatory.

New London, a city of Connecticut, U.S., on the Thames River, 3 miles from its entrance into Long Island Sound, 50 E. of New Haven by rail. It communicates daily with New York and Boston by rail, and daily with New York by steamer, is protected by Fort Trumbull, and has one of the finest harbours on the Atlantic. Its industrial products are chiefly cottons, woollens, ironwares, and biscuits. Pop. (1870) 9576.

Newman, John Henry, the son of a banker, was born in London, February 21, 1801, and educated at Ealing. As a boy of fourteen, although 'very superstitious,' he found pleasure in the works of Paine and Hume, but in 1816 a study of Romaine and other Calvinist writers effected an 'inward conversion of which,' he says, writing in 1864, 'I am still more certain than that I have hands and feet.' From this year too he dates his vocation to celibacy. Entering Trinity College, Oxford (1817), he graduated (1820), was elected a fellow of Oriel (1822), took orders (1824), and was Whately's vice-principal at Alban Hall (1825). In 1826 he became a tutor of Oriel, and beginning to be known by one or two essays and university sermons, came out of his shell, and remained out of it till 1841. Bred in a Liberal and Evangelical school, N. gained the opinions that led him along the 'Via Media' to Catholicism from Anglican divines, living and dead,—the doctrine of Baptismal Regeneration from Sumner's *Treatise on Apostolical Preaching*, of a Visible Church from Butler's *Analogy*, of Tradition from Dr. Hawkins, and of Apostolical Succession from the Rev. W. James, while from Whately he imbibed those anti-Erastian views that mark Tractarianism (q. v.). A study of Church history and Patristic theology taught him how Donatists and Arians had 'protested' and passed away, and his friendship with Keble, Pusey, and Hurrell Froude developed in him an admiration of the Church of Rome and dislike of the Reformation, a belief in the Real Presence, and a devotion to the Blessed Virgin. Vicar of St. Mary's and chaplain of Littlemore (1828-43), he visited Italy (1832), where he wrote *Lead, Kindly Light*, and other hymns marked δ in the *Lyra Apostolica*; edited the *British Critic* (1838-41); and wrote twenty-four of the *Tracts for the Times*, the condemnation of the last and nineteenth of which, on the 'elasticity' of the Thirty-nine Articles (1841), was followed by N.'s resignation of his livings (1843) and reception into the Catholic Church (October 8, 1845). During the Oxford and Protestant portion of his life, he published the *Life of Apollonius Tyaneus* (1824), *History of the Arians* (1833), *Parochial Sermons* (8 vols. 1838-44), *Annotated Translation of St. Athanasius* (1842-44), &c. Shortly after his conversion, N. was ordained priest at Rome, and became head of the Birmingham Oratory; in 1854 he was appointed rector of the Catholic University of Dublin; and since 1858 he has conducted a higher-class school at Edgbaston, near Birmingham. In the Catholic Church N.'s position is somewhat like Falkland's in the camp of the Royalists. His convictions are at variance with his sympathies, and the *Reply to Mr. Gladstone* (1875) is characterised by a 'minimising' interpretation of the Vatican Decrees, being less a confutation of the statesman than a subtle attack on the 'insolent and aggressive faction' of the Ultramontanes. Other works of N. are *Loss and Gain*, or *the Story of a Convert* (1848), *Anglican Difficulties*

(1850), *Lectures on the Turks* (1854), *Office and Work of Universities* (1854-56), *Apologia pro Vita Sua* (1864), *Grammar of Assent* (1870), and a *Collection of Poems* (1868), in which the *Dream of Gerontius* discovers a true poetic spirit. See Leslie Stephen's *Dr. N.'s Theory of Belief* in the *Fortnightly* (1877). —**Francis William N.**, brother of the preceding, was born in London, June 27, 1805, and passed from a private school at Ealing to Worcester College, Oxford (1822). He obtained a double first and Balliol fellowship (1826), but refusing from conscientious scruples to subscribe the Thirty-nine Articles for a master's degree, resigned his fellowship (1830), and quitted England for a three years' tour in the Levant. On his return he became classical tutor at Bristol College (1834), and at Manchester New College (1840), and in 1846 was appointed Latin professor in University College, London. This post N. resigned in 1863, and has since wholly devoted himself to literature. Diametrically opposed to his brother in religion, N. in *The Soul, her Sorrows and Aspirations* (1849), seems to incline to Positivism; in *Phases of Faith: Passages from my own Creed* (1850), traces his gradual divergence from Anglican orthodoxy; whilst his *Theism* (1858) is opposed at once to the negations of atheism and the pantheism of Spinoza. N. has also published an immense number of works on ethics, philology, mathematics, and general literature, among them *History of the Hebrew Monarchy* (1847); *Lectures on Political Economy* (1851); *Regal Rome* (1852); translations of the Odes of Horace (1853) and the Iliad (1856) into unrhymed English metres; *Miscellaneous Academic and Historical* (1869); *Europe of the Near Future* (1871); a Berber Grammar; Arabic Dictionary (1871), &c.

Newmarket, the racing capital of England, stands partly in Suffolk, partly in Cambridgeshire, 61 miles N.N.E. of London by rail. It contains the church of St. Mary (restored 1867), a Congregational chapel (erected 1863 on the site of a palace of Charles II.), the mansion of the Jockey Club, and numerous training establishments. The Beacon Racecourse, upwards of 4 miles long, is the finest in the world. There are seven annual meetings, and the great events are the Two Thousand, run in April, and the Cesarewitch in October. (See HORSE-RACING.) The 'Devil's Dyke,' a remarkable hollow 100 feet broad, extends for 5 miles along the Downs, and probably served as the 'march' or border between the kingdoms of East Anglia and Mercia. Pop. (1871) 4534.

New Mexico, a south-western territory of the U.S., is bounded N. by Colorado, S. by Texas and Mexico, E. by Texas and the Indian territory, and W. by Utah and Arizona. Area, 121,201 sq. miles. Pop. (1870) 111,303, including 19,429 Indians. It is 380 miles long from N. to S., and 352 broad from E. to W., and is traversed throughout from N. to S. by the Rio Grande, the valley of which (20 miles wide) separates the Rocky Mountains from the Sierra Madre. The whole territory is a continuation of the great Mexican tableland, from 3000 to 6000 feet above the sea. From this plateau several peaks of the Sierra Madre (Mount Taylor, Topped Peak, &c.) tower to a height of 10,000 feet. The S.-eastern portion of the territory is occupied by part of the Llano Estacado ('staked plain'), where the mesquite or gama-grass, valuable as forage for cattle, grows to a height of from 5 to 20 feet. The Rio Grande receives in N. M. the waters of the Pecos, Chama, and Puerco; the N.E. of the territory is irrigated by the Canadian River, and the W. by the affluents of the Colorado. Forests of pine, cedar, spruce, and other evergreens cover the mountain-sides; while the foot-hills and river bottoms have extensive tracts of piñon or nut-pine, cotton-wood, sycamore, and other deciduous trees. In the S. and S.W., the cactus-tree is a marked feature in the landscape. The rocks of the plateau are cretaceous, those of the two great mountain ranges Eozoic. There are three considerable volcanic tracts, marked by lava and by volcanic sand alternating with salt marshes. Gold and silver are abundant, but the ores are mostly 'base,' yielding in general only from \$50 to \$85 per ton. In 1874 the total yield of gold was valued at \$500,000. Copper is also found in very rich ores in several parts, the Santa Rita mine alone producing 3000 lbs. of copper weekly. Galena mines in the Oregon mountains yield 80 per cent. of pure lead, besides \$50 worth of silver to the ton. Other minerals existing in N. M. are lignite, bituminous coal, anthracite, iron, and salt. The crops are chiefly wheat, Indian corn, oats, and barley, but in 1874 also included 8587 lbs. of tobacco and

19,686 gallons of wine, and had a total value of \$1,905,060. In 1874 N. M. had 26,500 horses, 6141 mules and asses, 202,718 cattle, 619,438 sheep, and 11,267 swine—total value, \$2,389,157. A considerable traffic is carried on by waggons with Santa Fé, the capital (pop. 4765), and the mineral produce is conveyed by Denver to St. Louis or San Francisco. There are neither railways nor navigable rivers. In 1873 the Indians were reported to number 14,389 Utes, Apaches, and Navajoes (4278 warriors), and 7683 Pueblos, or peaceful village Indians. The Utes and Apaches alone are hostile and thievish. As early as 1537 the Spanish adventurer Alvar Nunez penetrated to this region, and between 1595 and 1599 the Spaniards here established forts, mining colonies, and missions. N. M. was ceded to America at the close of the war with Mexico in 1848, and made an independent territory in 1850.

New Orleans, the capital and the principal city and port of entry of Louisiana, U.S., beautifully situated on both banks of the Mississippi, but chiefly on the left or N. bank, 115 miles above its entrance into the Gulf of Mexico. The general direction of the river is here from E. to W., but a curve or bend in its course has given N. O. the name of the 'Crescent City.' Extending some 10 miles along the N. bank, the city is built entirely on the alluvial bank, and below high-water level, being protected from the yearly floods by a levee raised in front and extended back to Lake Pontchartrain, into which also the rainfall, sewage, and seepage is driven by powerful machinery. The flood-water rises here 15 feet above the level of the Gulf of Mexico. N. O. is the tenth city in the U.S., the junction of three important railways, and the centre of a vast network of steamship lines. The river, lined with wharfs and approached by fourteen landings, is crossed to the recently annexed suburbs of Gretna and Algiers on the S. by eight steam-ferries. Throughout the city stretch 67 miles of street railroads, on part of which are used the celebrated fireless engines. Among the chief buildings are the custom-house, in Quincy granite, the cathedral, court-halls, a white marble city-hall, the university, state-house (the St. Louis Hotel till 1874), and various hotels and theatres. Of 142 churches, 36 are Roman Catholic, 25 Baptists, 11 Episcopal, 5 Evangelical, 19 Methodist Episcopal, 11 other Methodists, 12 Presbyterian, 6 Jewish, 3 Lutheran, 1 Swedenborgian, 1 Unitarian, and 1 Greek. The streets in the original or old French part are narrow and irregular, those in the American part are spacious and elegant, in many cases shaded with beautiful trees. There are 11 public parks and squares, 3 commercial canals, 12 draining canals, and 16 markets. Among the charities are 46 asylums, 12 hospitals, and 3 infirmaries. The University of Louisiana, the literary department of which is at Baton Rouge, and is under military discipline, has here 14 professors in law, medicine, &c. The number of public schools is (1876) 147, with 471 teachers and 14,235 pupils. There are twenty-four newspapers—six daily (one French) and eighteen weeklies. The festival preceding the first day of Lent is observed as the carnival of the city, and is called *Mardi Gras*, or 'Flat Tuesday.' N. O. has long been the chief cotton-mart of the world, as well as one of the leading sugar-marts. Its trade reached its climax in these two staples in 1861, when there were received from the interior 2,255,448 bales of cotton, and 460,000 hogsheads of sugar. In 1875 the receipts of cotton were 1,157,597 bales; of sugar, 154,779 hogsheads; of molasses, 337,916 barrels; of tobacco, 8636 hogsheads; of rice, 104,415 barrels; of flour, 917,982 barrels; of wheat, 145,000 bushels; of hay, 60,000 bales; of pork, 72,000 barrels; of bacon, 25,000 casks; and of lard, 27,000 kegs. The total foreign imports in 1874 amounted in value to \$14,506,940, and the duties thereon to \$2,992,592; the foreign exports to \$93,259,289. The chief articles of export were cotton, 999,492 bales, valued at \$67,275,000; tobacco to the value of \$1,214,794; and staves to that of \$662,000. In the absence of good water-power the manufactures are neither extensive nor valuable. They employ, however, 517 steam-engines and 5640 operatives. The climate is not extreme, the temperature averaging about 69° F., but the marshes and shoal-waters in the vicinity cause much yellow fever. Pop. (1873) 205,000. Settled by the French in 1718, N. O. passed with Louisiana to the U.S. in 1804, when it had 10,000 inhabitants. During the Civil War it was closely blockaded, and finally forced to surrender to the Federal commander Farragut, 24th April 1862.

Newport, a river-port of England in Monmouthshire, stands on the right bank of the Usk, 4 miles above its mouth, and 12 N.E. of Cardiff by rail. It contains four churches, a castle (now converted into a brewery), a town-hall, custom-house, assembly-rooms (1861), market-house (1865), mechanics' institute, &c. A dock of 4½ acres was opened here in 1842, a second of 7½ acres in 1858, and the Alexandra Dock, now (1877) approaching completion, is larger than either of its predecessors. In 1876 there entered the port 4035 vessels of 578,695 tons, and cleared 8703 of 967,706 tons. The imports in the same year amounted to £520,942; the exports to £1,043,789; and the customs to £50,179. As the junction of five lines of railway N. offers great facilities for the exportation of the coal and iron of the surrounding districts, and grain and timber are largely imported. There are shipbuilding and timber yards, chain-cable works, iron foundries, a shot manufactory, breweries, &c. With Usk and Monmouth N. returns one member to Parliament. Pop. (1871) 27,069. N. was anciently the port of Caerleon (q. v.), was held by the Earls of Hereford and Dukes of Buckingham, and was the scene of a great Chartist riot, November 4, 1839.

Newport, a town of England, capital of the Isle of Wight, 5 miles S. of Cowes by rail, at the head of the Medina estuary. It contains the church of St. Thomas (rebuilt 1857), with a monument to the Princess Elizabeth (daughter of Charles I.), erected by the Queen from designs by Marochetti, two other churches, a guildhall (1816), museum, assembly-rooms, &c. Near the town are the Parkhurst Barracks, with accommodation for 3000 soldiers, and the remains of Carisbrooke Castle. N. has manufactures of lace, mats, brushes, &c., and a trade in iron, flour, timber, and malt. It returns one member to Parliament. Pop. of municipal borough (1871) 7956.

Newport, a city of Kentucky, U.S., on the S. bank of the Ohio River, opposite Cincinnati, and separated from Covington by Licking River on the W., has a court-house, 16 churches, and numerous benevolent institutions. Its chief manufactures are in iron and steel. A detachment of United States troops is stationed here. N. communicates with Cincinnati and Covington by two suspension bridges and by steam ferry-boats. Pop. (1870) 19,802.

Newport, one of the capitals of Rhode Island, U.S., at the head of Narragansett Bay, 70 miles S. by W. of Boston, with which it is connected by rail and by a line of steamers. It has 14 churches, 2 libraries, and a daily newspaper, and is the torpedo station for the U.S. Fort Adams, one of the largest fortifications in America, is situated 1½ miles S.W. of the city. N. has many antiquities, and is much resorted to by families in summer for sea-bathing. In 1875 the annual entrances and clearances of shipping amounted to 668, with a total tonnage of 1,609,224. Pop. (1870) 12,521. Founded by Roger Williams and his followers in 1638, N. has been the annual meeting-place of the Society of Friends for upwards of 230 years.

Newport-Pagnell, a market-town of England, in Buckinghamshire, on the Ouse, 28 miles N.N.E. of Aylesbury, has a fine parish church, restored by Street in 1858, a paper-mill, coachbuilding establishment, and a soda-water manufactory; and a trade in coal brought from Staffordshire by a branch of the Grand Junction Canal. Pop. (1871) 3824.

New Red Sandstone. See TRIASSIC PERIOD.

New Ross, a river-port of Ireland, partly in Wexford and partly in Kilkenny, is situated on the Barrow, 12 miles N.N.E. of Waterford by rail. It has a commodious harbour, with new quays erected at a cost of £3000, and the principal industries are brewing, tanning, and the salmon fisheries. In 1876 there entered the port 628 vessels, of 62,382 tons; and cleared 493 of 46,674 tons. The imports in the same year amounted to £115,453; the exports to £4763; and the customs to £11,026. N. R. returns one member to Parliament. Pop. (1871) 7339. In the annals N. R. is called *Ros-mic-Treoin* ('the wood of Treun's son'), and in spite of its name is a very old place.

Newry, a seaport of Ireland, in the counties of Down and Armagh, situated at the head of Carlingford Lough, on a small river of the same name and a canal leading to Lough Neagh (32 miles), 15 miles N. of Dundalk by rail. N. has Episcopal,

Presbyterian, Wesleyan, and Roman Catholic churches, three banks, and two newspapers. Linens, woollens, flour, spirits, beer, and leather are manufactured, and there is considerable trade in grain and provisions. In 1876, 1011 vessels of 260,647 tons entered, and 920, of 217,125 tons, cleared the port. In the same year the imports amounted to £525,208, and the customs to £18,574. N. returns one member to Parliament. The name N. is a corruption of the Irish Gael. *Iubhar-cinn-tragha* ('the yew-tree at the head of the strand'). The town was chartered in the reigns of James I. and II. In 1689 it was partly burned by the Duke of Berwick. Pop. (1871) 13,364.

New Siberia, a group of uninhabited islands in the Arctic Ocean, N.E. of the mouth of the Lena, between 70° 50' and 76° 20'. Area, 20,728 sq. miles. These islands, the largest of which are Novaia Sibir (Russ. 'New Siberia'), Fadjevskij ('Thaddeus' Island'), Kotelnoi-Ostrov ('Kettle Isle'), and Blisnii or Lachowsky ('Lachow's Isle'), afford great quantities of primitive ivory, for which, and for the whale fishery, they are annually much frequented. Novaia Sibir was discovered in 1760, the rest before 1805; and in 1823 the group was surveyed by Lieutenant Anjou.

New South Wales, a British colony in the E. of Australia. It originally included all of that continent to the E. of the 135th meridian of E. longitude, but this unwieldy area was greatly reduced by the successive formation of the colonies of S. Australia (1836), Victoria (1851), and Queensland (1859). The present boundaries of N. S. W. may be generally described as follows:—On the N. the 29th parallel of S. latitude, the Dumaresq river and the Macpherson range; on the E. the Pacific Ocean; on the S. the River Murray and a land-line from the head of that stream to Cape Howe; and on the W. the 141st meridian of E. longitude. The total area of the colony is 323,437 square miles, or about three times that of the United Kingdom. N. S. W. was discovered by Captain Cook in 1770, and definitely taken possession of by Great Britain on 26th January 1788.

N. S. W. may be divided, physically, into four principal regions, viz.:—1. The coast and mountains, the former for the most part consisting of an alluvial plain of wonderful fertility, watered by numerous rivers, while the mountains form a portion of the great Australian Cordillera (see AUSTRALIA), and in N. S. W. are composed of seven ranges, including the highest land in Australia. They consist largely of primary rocks, but more usually form precipitous ridges than sharp peaks. 2. The tablelands, which lie to the W. of the Dividing Range, and are composed of a floor, so to speak, of primary rocks, overlaid with metamorphic rocks. 3. The western slopes, which form undulating downs, gradually merging into the fourth region, known as the Saltbush Plains from its being covered with a species of mesembryanthemum, whose saline berries are readily eaten by sheep. These plains belong to the Tertiary formation in common with most of the rest of the interior of Australia. The watershed is formed by the Dividing Range, whose proximity to the sea causes all the longest rivers to flow inland. Their names, reckoned from N. to S., are—The Darling (q. v.), Bogan (q. v.), Lachlan (q. v.), Murrumbidgee (q. v.), and Murray, the last belonging equally to Victoria. For part of the year all these rivers are navigable by steamboats of light draught. The rivers of the eastern watershed are shorter and more impetuous, being all more or less liable to heavy floods. The chief of them, from N. to S., are—The Clarence, Shoalhaven, Hunter, and Hawkesbury (q. v.). Lakes are very few and insignificant, but the Liverpool Plains (q. v.) are believed to have been at one time the bed of an immense lake, and in the western plains, especially near the confluence of the rivers which unite to form the Darling, and at the junction of the Lachlan with the Murrumbidgee, a large extent of country is usually under water in winter. The coast of N. S. W. is bold and rugged, and besides the splendid inlet of Port Jackson (q. v.), possesses good harbours at Twofold Bay and Port Stephens.

The climate of N. S. W. is necessarily very diversified, but it is almost everywhere salubrious. The highest mountains scarcely reach the line of perpetual snow, and on the coast snow rarely falls. At Sydney the mean annual temperature is 65°, and the annual rainfall 49·94 inches. The heat on the plains of the interior is excessive, reaching 100° in the shade during a great part of the year, and the same region is also liable to prolonged periods of drought.

The flora of N. S. W. is varied and interesting. Among the principal trees are the various kinds of Eucalyptus (q. v.), wattle, and Casuarina (q. v.). The first-named yield timber which in size and quality is almost unrivalled, and many of the smaller trees of the colony furnish handsome ornamental woods. Ferns and wild flowers grow in profusion, but the wild fruits are few. The total area under crops of all kinds on 31st March 1876 was 451,139 acres, the two principal crops being wheat (133,609 acres) and maize (117,582 acres). Oats are grown chiefly for fodder, and the cultivation of potatoes is limited. 6453 acres were under the sugar-cane, and 4458 acres under the vine. The yield of sugar was 2,310,860 cwt., and of wine 831,749 gallons. 19,407 acres were cultivated as gardens and orchards, orange-growing being an important industry in N. S. W. Among the other crops are barley, rye, millet, tobacco, and arrowroot.

N. S. W. abounds in animal life, the indigenous fauna including kangaroos of all kinds, the wombat, opossum, bandicoot, koala or native bear, echidna, ornithorhynchus, and many species of bat. Among the birds the most numerous are cockatoos, parrots, owls, pigeons, and quails. The Laughing Jackass (q. v.) is also common, but the Emu (q. v.) has been driven to the remoter parts of the interior. Snakes are plentiful and very venomous, the most dreaded species being the death-adder and yellow snake. Insects are abundant to the last degree, and include many which are very obnoxious to man.

The mineral wealth of N. S. W. is very great, including coal in boundless quantity, besides gold, silver, iron, tin, copper, manganese, platinum, and precious stones. The value of the principal mineral exports during 1876 was as follows:—Coal, £1,319,918; kerosene shale, £47,994; tin, £439,638; copper, £249,978; silver, £15,456. During the same year 153,531 oz. of gold, valued at £600,000, were sent to the Sydney mint. As yet, however, the pastoral interest is the most important one in the colony, the live stock of which amounted in 1875 to 22,872,882 sheep, 2,856,699 cattle, and 346,691 horses. The sheep outnumbered those in all the other Australian colonies put together. Large numbers of horses run wild in the interior, and are frequently slaughtered for their hides. The wool shipped from N. S. W. in 1875 amounted to 87,500,000 lbs., of the value of £5,651,643, besides tallow, skins, and hides to the value of £306,000, and preserved meats to the value of £70,000. The total value of the exports of all kinds in 1876 was £8,277,520, and of the imports £11,567,485. The revenue for the same year was £5,037,661, of which £2,772,999 was derived from land, £1,000,000 from customs, and £678,391 from railways, of which there were 450 miles open. Favoured by the abundance of coal, the manufactures of N. S. W. are numerous and increasing, in spite of its free-trade policy. The most important are iron foundries and engineering works, shipbuilding, saw and flour mills, leather, woollen-cloth, and meat-preserving factories, breweries, distilleries, and sugar refineries.

From its foundation in 1788, N. S. W. continued to be a penal settlement until 1849, when the transportation of criminals there was stopped in consequence of a very strong agitation in the colony against it. Two years later the discovery of gold near Bathurst (q. v.) caused a great influx of population, and started the colony on its prosperous career. N. S. W. is governed by a governor appointed by the Crown, assisted by an executive council of seven, who are responsible to a Parliament composed of two Houses—the Legislative Council and the Legislative Assembly. The former consists of not less than 21 members, all nominated by the Crown; and the latter of 72 members, elected by 60 constituencies. The suffrage is practically universal, and the parliaments are triennial. N. S. W. is subdivided into 118 counties, 99 of which are grouped under 13 pastoral districts. The pop. at the end of 1875 was officially estimated at 406,652. The capital is Sydney (q. v.), and the other chief towns are Newcastle (q. v.), Maitland (q. v.), Parramatta (q. v.), Bathurst (q. v.), and Goulburn. See *Gazetteer of N. S. W.*, by R. P. Whitworth (Sydney, 1866); *N. S. W. the Mother Colony of the Australias*, by G. H. Reid (Sydney, 1876); *The Australian Handbook for 1877* (Lond. 1877); *Mines and Mineral Statistics of N. S. W.*, by the Hon. John Lucas and Rev. W. B. Clarke (Sydney, 1875).

Newspapers. Although the *Acta Diurna* of the Romans contained daily official reports, and the Chinese claim to have

had a similar journal of much greater antiquity, N. are almost entirely the growth of modern times. The earliest regular newspaper we know anything of is the *Notizie Scritte*, published in MS. at Venice about the middle of the 16th c. This paper was to be seen at various places in the city, a small coin (*gazeta*) being charged for the privilege; hence the term 'Gazette.' There is some obscurity regarding the date of the first English newspaper. Copies of a print in the British Museum entitled the *English Mercury*, purporting to give news of the Spanish Armada, &c., have been conclusively proved to be forgeries. Not long afterwards, however, we come to the 'era of Mercuries,' these being casual publications, issued in the interests of various cliques, parties, and professions, rather than N. There was the *Mercurius Pragmaticus*, the *Mercurius Bellicus*, the *Laughing Mercury*, and Mercuries of all kinds. A favourite medium of supplying intelligence was in the form of 'news' letters, written to provincial magnates by residents in London, who sent their patrons the news of the courts and markets, and regaled them with the talk of the town and the gossip of the coffee-houses. In 1622, one of these letter-writers, N. Butter, printed the *Certaine News of the Present Week*, which was followed by a whole host of similar one-pageed weeklies. In its early stages newspaper-writing was hot and spicy, brimful of personalities, and coarse and vituperative epithets, bearing no small resemblance to a style which is common at the present day 'out West' in America, but destitute of the grotesque and diverting humour of New World animosities. One journal was often started simply to fight or cry down another, the *Weekly Discoverer* being followed, for example, by the *Discoverer Stripped Naked*. The news was chiefly limited to foreign affairs, domestic matters being scarcely discussed till after the abolition of the Star-Chamber. During and after the Civil War the Royalists and Republicans had their organs in the press, perhaps the most able writers on either side being Sir John Birkenhead in the former, and Marchmont Needham in the latter party. Under Charles II. a strict censorship of the press was established, and no journals were permitted save those authorised by the unscrupulous licenser of the press, Sir Roger L'Estrange, himself publisher of the *Observer*. The Government paper, *The London Gazette*, two pages in size (started in 1665), came out on Mondays and Thursdays. Although the experiment had been repeatedly tried before, the first daily newspaper that established itself firmly was the *Daily Courant* in 1709, which consisted of one page of two columns. The imposition in 1713 by Act 10 Anne, c. 17, of a stamp duty of 1d. on N. larger than half a sheet (½d. if otherwise), which tax was gradually increased by various statutes (in 1756, 1789, and 1797) till it amounted to 4d., was a great hindrance to the progress of the press in the 18th c. Among the most famous papers of this period may be mentioned *The Public Advertiser* (started as the *London Daily Post* in 1726), which had attained at the time of Junius' Letters to its publisher a circulation of from 6000 to 7000; the notorious but short-lived *North Briton* of John Wilkes, which ran through 217 numbers (No. 45 being burned by the common hangman); *The Englishman* and *London Evening Post*, which were both indebted to the classic pen of Edmund Burke; and the *Jesuit*, a Whig organ, satirically so called, launched by Sheridan in 1782. At the beginning of the 19th century the leading London papers were the *Morning Chronicle*, the *Morning Post*, and the *Times*. The *Chronicle* (founded in 1766) had three remarkably able editors in succession—Woodfall, Perry, and Black—and was for a considerable time the leading journal. The *Post* (1772), then as now, was the fashionable paper *par excellence*, and impressed much of the literary genius of the day into its service. The *Times* was established by the first John Walter in 1785 as the *Daily Universal Register*, assuming its present name in 1788. In 1800 it had a circulation of 1000, greatly less than that of the *Chronicle* or *Post*. In 1803 the second John Walter became manager and joint-proprietor, and under his energetic sway it grew to be the greatest paper on the globe. It owed its success firstly to the business capacity of Mr. Walter, who saw that the newspaper which gave the earliest and the best news would command the greatest amount of public favour, and who acted energetically on that conviction. It was also greatly indebted for its success to the independent tone of its leaders, and the high talent of its contributors, while the application of steam-power to its printing-press in 1814, enabling 1100 copies to be thrown off in an hour,

or more than four times the number of any other daily, gave it a great impetus. Mr. Barnes held the editorship from 1814 to 1841, when he was succeeded by J. T. Delane, who has now (1877) resigned, and is succeeded by Mr. Chenery, Professor of Arabic in Oxford University, and who has long been a contributor. The *Times* appeared as an eight-page paper (forty-eight columns) on January 29, 1829. In 1846 its average circulation had reached 23,000, and in 1854, during the Crimean War, when W. H. Russell's brilliant letters initiated the War-Correspondence feature of modern journals, attained an average of 51,648, or twice that of all the other London dailies. In 1836 the Act 6 and 7 William IV. c. 76, imposed, in place of the old 4d. tax, a duty of 1d. on a newspaper containing 1530 square inches, 1½d. if above 1530 and under 2295 square inches, and 2d. if the latter size, a reduction signalled by the establishment of sixty-one new papers in Great Britain. This tax was altered to 1d. for every sheet under 2295 square inches in 1853, and by Act 18 Vict. c. 27, was finally abolished in 1855. The 5d. papers (followed shortly by the *Times*) reduced their price to 4d., and a number of penny dailies were started, the most successful of which have been the *Daily Telegraph* (1855), and the *Standard* (1857). Various statutes have since been passed which have greatly helped the wonderful development and popularising of N. The paper-duty was repealed in 1861, when the *Times*, *Morning Post*, and other papers reduced their prices to 3d., and a number of penny papers increased their size from four to eight pages. In 1869, by Act 32 and 33 Vict. c. 24, the provisions in Act 1 Will. IV. c. 73, and 6 and 7 Will. IV. c. 76, requiring deposits of sureties and other burdens, were cancelled. The present power of the press can scarcely be exaggerated. The fierce light it has thrown upon every social and national abuse, the searching and minute criticism of every step in legislation, the full, free, and untrammelled expression it has given to the nation's voice, have not unfrequently decided the fate of measures and of administrations. It is impossible to estimate the importance of N. socially, commercially, and politically. The completeness, variety, and extent of news in every impression of the *Times* is indeed one of the greatest triumphs of civilisation.

The staff of a leading London newspaper includes the editor-in-chief, the assistant-editor, the city editor, having charge of the commercial news, leader-writers and other contributors, the sub-editors, dealing with various departments, and a complete corps of reporters and local correspondents. It has a representative in most of the great capitals in the world, from whom and from Reuter's Telegram Company foreign telegrams are constantly obtained. In the year 1877, 74 reporters were accommodated in the two Houses of Parliament. They represented the various London dailies and news associations supplying the provincial papers. These associations are assumed to represent sufficiently the papers out of London; but a feeling prevails strongly that the more important of the latter should have access to the Reporters' Gallery. At present (1877), while the leading country dailies spend large sums of money to get their own reports of Parliamentary debates, they have no recognised right of admission for their reporters. The less important country papers rely for their Parliamentary reports exclusively upon the Press and Central News Association. In the busy life of the age, newspapers form the only reading of thousands of people, and must therefore be made as universal in contents as possible. Besides the leaders, telegraphic intelligence, and paragraphs, its columns are accordingly opened to reviews of current literature, notes of travel, musical and dramatic criticism, approved letters from correspondents, &c. The machinery used in printing the great papers (by the Walter, Hoe, Victory, &c., presses) is of the most perfect description. The Walter Press has printed the whole impression of the *Times* since 1870. The paper is supplied in huge long rolls, and is printed, cut, and folded by one machine at the rate of from 12,000 to 15,000 copies an hour. The enormous expense of a paper is seldom covered by a sale however large, and proprietors therefore look to advertisements for their profit. The highest-class journals do not solicit advertisements, but the majority of papers have regular canvassers in the advertising department.

According to Mitchell's *Newspaper Press Directory* for 1877 (an annual and useful publication), there were in the beginning of that year 1692 newspapers in the United Kingdom, as follows:—

England—			
London	.	.	320
Provinces	.	.	991
			— 1311
Wales	.	.	56
Scotland	.	.	164
Ireland	.	.	141
Islands	.	.	20

1692

Of those published in the Metropolis, 18 only were daily (13 morning and 5 evening) papers; 5 of these were purely commercial journals, and 1 (the *Sportsman*) a turf paper.

CHIEF LONDON MORNING PAPERS.

Newspapers.	Founded.	Price.	Politics.
<i>Times</i>	1788	3d.	{ Liberal, but reflects Na-
<i>Morning Post</i>	1772	3d.	tional Opinion.
<i>Morning Advertiser</i>	1794	3d.	Conservative.
			Independent.
<i>Daily Telegraph</i>	1855	1d.	{ Liberal in Domestic,
			Maintenance of 'British
			Interests' in Foreign
			Politics.
<i>Standard</i>	1857	1d.	Conservative.
<i>Daily News</i>	1846	1d.	Liberal.
<i>Daily Chronicle</i>	1855	1d.	Liberal.

The ordinary size of the *Times* is 16 pages, but frequently it extends to 20 pages. The strictest censorship is exercised in the advertisement department, and its revenue from that source is the greatest in the kingdom. Original telegraphic intelligence is published every morning from all the leading cities of Europe and various parts of the world. Everything necessary for the production of the paper (except ink and paper), including printing presses, types, &c., is manufactured at the *Times* office, which is characterised by completeness of arrangement and perfection of mechanical details. Next to the *Times*, the highest place must be given to the *Telegraph*, the *Standard*, and the *Daily News*, which are admirably conducted in every department. The *Telegraph* is understood to have the largest circulation (average 267,189, October 1877), and the *Standard*, which has long been famous for its parliamentary reports, probably comes next to it (199,000, morning and evening issue, October 1877). As an instance of the public spirit of the *Telegraph*, the recent expedition to Central Africa of Mr. Stanley at the joint expense of that paper and the *New York Herald* deserves recognition. The *Daily News*, started with Charles Dickens as editor in 1846, reduced from 3d. to 1d. in 1868, signalled itself in 1876 by obtaining earlier information of the Bulgarian massacres from its representatives in the East than the Government from Her Majesty's Consuls, and by the letters telegraphed by Mr. Archibald Forbes during the Russo-Turkish struggle (1877)—in many respects the best war correspondence which the history of journalism records.

CHIEF LONDON EVENING PAPERS.

Newspapers.	Founded.	Price.	Politics.
<i>Pall Mall Gazette</i>	1865	2d.	Independent.
<i>Globe</i>	1803	1d.	Conservative.
<i>Evening Standard</i>	1827	1d.	Conservative.
<i>Echo</i>	1868	1d.	Liberal.

The *Pall Mall Gazette* must be allowed the palm for literary excellence. The halfpenny *Echo* has a larger circulation than all the other evening papers combined. The circulation of the London dailies (78,000 in 1854) is probably in 1877 not less than 1,000,000.

In January 1877, 9 papers were published in London twice a week, 5 three times a week, 247 weekly, and 41 fortnightly and monthly. The non-daily papers are for the most part local, trade, class, or sectarian organs. The *Observer*, published every Sunday (price 4d.), gives late, reliable, and important news. The *Mail*, published in connection with the *Times*, contains a weekly summary of the best of that journal. *Lloyd's News* (1842) and *Reynolds' News* (1850) take the lead among the many widely-circulating working-class weeklies. The circulation of *Lloyd's* is said to exceed half a million. The highest place among critical journals must be assigned to the *Saturday Review* (1855), the *Spectator* (1828), and the *Examiner* (1808). The *Athenæum*

(1828) is the first literary weekly, its most successful rival being the *Academy* (1869). The *London Gazette* (1665), published on Tuesdays and Fridays, price 1s., is the appointed organ for all announcements of the Government. Among the papers printed in foreign languages are the *Courrier de l'Europe* (French), and the *Londoner Zeitung* (German). The *Illustrated London News* (1842) and the *Graphic* (1869) are *facile principes* as illustrated N. *Punch* is undoubtedly the best comic publication the world has ever seen. Its cartoons are often masterpieces of satiric or pathetic humour; its other illustrations have reflected with marvellous felicity the inexhaustible phases of English life. Its first editor, Mark Lemon, gathered about him the brightest wits in London, and gave it a tone at once popular and refined, which it has sustained with ease to the present day. *Judy*, *Fun*, *Figaro*, *Funny Folks*, &c., are engaged in the manufacture of jokes for the million. *The World*, started in 1874, and its subsequent imitators, *Truth*, *Mayfair*, &c., are dear to the lovers of piquant scandal and unscrupulous banter.

Of the 991 English provincial papers, 54 were morning (15 Conservative, 23 Liberal, 16 neutral) and 29 evening (5 Conservative, 10 Liberal, 10 neutral) issues. 41 of the morning papers were priced one penny, 13 one halfpenny. With one exception (the *Cheltenham Evening Telegram*) all the evening were halfpenny papers. Liverpool has 7 daily papers; Manchester and Newcastle, 5; Birmingham, Leeds, and Sunderland, 4; Bolton, Bradford, Brighton, Bristol, Exeter, Hull, Leicester, Nottingham, and Sheffield, 3; Huddersfield, Middlesbrough, Plymouth, and Shields, 2; and Ashton, Banbury, Barrow, Bury, Cheltenham, Darlington, Dewsbury, Eastbourne, Gloucester, Ilanley, Ipswich, Newport, S. W., Norwich, Oldham, Penzance, Scarborough, Southport, Wolverhampton, and York, 1 each. 255 towns possess more than one weekly paper, the common size of which is eight pages, and the price usually one penny or twopence. As a rule the provincial dailies will not stand comparison with the metropolitan. We may mention, however, the *Manchester Guardian* (which has rivalled the London papers in lateness and accuracy of home and foreign news), the *Manchester Examiner*, the *Liverpool Courier*, the *Liverpool Mercury*, the *Leeds Mercury*, and the *Newcastle Chronicle* as brilliant examples of the energy, intelligence, and culture of the English provinces.

In Scotland there were 12 morning and 6 evening papers, of which 9 proclaimed themselves Liberal, 2 Conservative, and 7 Independent or neutral; 5 were published in Edinburgh and Leith, 6 in Glasgow, 3 in Dundee, 2 in Aberdeen, 1 in Greenock, and 1 in Paisley. The earliest Scotch newspaper was the *Caledonian Mercury*, which as the *Mercurius Caledonius* made a spasmodic appearance as far back as 1660. This ancient print some twelve years ago finally merged into the *Weekly Scotsman*. The *Edinburgh Courant*, the Conservative and Established Church organ, has a history dating from 1702. It has not of late years received adequate support from its party, but it is now striving with unwonted energy for recognition as the organ of the liberal and cultivated Conservatives. The *Scotsman*, founded in 1817 in the Whig interest, has always been one of the ablest and most consistent of that party's organs, and fought the battles of Reform and Free Trade with indefatigable vigour. Under the editorship of Charles M'Laren, J. R. M'Culloch, and particularly Alexander Russel, it distanced all competitors, and has now (1877) attained a circulation of 60,000, being immensely greater than that of any paper in Britain out of London. Mr. Russel received in 1875 a compliment never before or since paid to a journalist, when he was elected an honorary member of the Reform Club, in acknowledgment of his services to the Liberal cause. The *Scotsman* was the first to initiate various enterprises, in which it has been followed with commendable alacrity by several other Scotch papers, such as the establishment of special telegraphic wires to London and the running of special trains to different parts of the country for the transmission of early editions. It also introduced the 'Walter Press' into the printing department before any other non-metropolitan journal. It has two special London wires and three Walter presses. Under its present management it has shown a resolute determination to throw off the reproach of provincialism (which Mr. Russel's editorship, brilliant though it was, tended to confirm), has boldly challenged the infallibility of the London Press, and on several notable occasions anticipated the latter in the publication of important news. It has also conspicuously widened the range of its intellectual sympathies—Literature, Education, and

Social Progress receiving a much larger and more liberal attention than formerly. The Edinburgh *Daily Review*, founded in 1861, took the place of the old *Witness* as the leading Free Church paper, and during the present year (1877) has specially signalled itself by an almost uninterrupted series of attacks on the Church of Scotland. It is certainly the most vehement and persistent organ of Disestablishment north of the Tweed. The *Glasgow Herald* (1782) is a remarkably well-written paper of great influence in the W. of Scotland. In politics, whether secular or ecclesiastical, it is candid, temperate, and rational. The space devoted to literature is a compliment to the intelligence of Glasgow. The *Herald* is understood to be the best newspaper 'property' in Scotland—next to the *Scotsman*. The *North British Daily Mail* (1847) has distinguished itself in social questions. Of all newspapers recently started in the United Kingdom, none has so speedily acquired such a position as the Conservative *Glasgow News* (1873), which has now (1877) passed from the hands of a company to that of a single proprietor. Three evening papers, the *Citizen*, *News*, and *Times*, are largely patronised. The first of these has long been noted for the literary felicity of its paragraph leaders. The leading newspaper in the N.E. of Scotland is the *Dundee Advertiser* (1801).

15 morning and 5 evening papers were published in Ireland (9 Conservative, 7 Liberal, and 4 neutral). Dublin had 8; Belfast, 6; Cork, 3; and Limerick, Londonderry, and Waterford, 1 each. The Irish papers are smaller in size as a rule than those published in Great Britain. The Dublin *Irish Times* and *Freeman's Journal*, the Belfast *Northern Whig*, and the Cork *Examiner* are among those most deserving of notice.

Before proceeding to a short review of the foreign press we may be permitted to point out how faithfully a country's N. reflect the national genius. The English paper, large and bulky, crammed full of advertisements, of political, legal, mercantile, and foreign news, bears witness to the busy life, commercial energy, and far-reaching interests of England, while the strong assurance and reliant tone of the leaders are indications of the inherent common sense and independent spirit of its people. The smaller and neater French journal, bright and vivacious, deals less with trade, but sparkles with witty paragraphs and incisive sentences; is full of airiness and raillery; devotes a *feuilleton* to novelettes, dramatic criticism, and gossip; and in the contrasted fierceness of its political articles betrays the weakness of unsettled institutions, and the sense of wrongs wrought by corrupt parties on a great and generous people. The German *zeitung*, careful and methodical in tone, stern, immovable, and unswayed by sentiment, is a reflex of solidity, iron determination, and national strength. But it also exhibits the pernicious influence of *bureaucratism* or government officialism. It is too often 'kept' or subsidised; and it shows frequent trace of the government scissors—in a word, it is able, but it is not free. Most pronounced of all are the characteristics of the American press, which in the form of extravagant advertisements, sensational headings, feverish activity, irrepressible go-aheadness, and sometimes of unblushing personalities, illustrate while they exaggerate the vices and the weaknesses of the nation. It would be unfair on the other hand to ignore the humour, sprightliness, keen sense, and generous enthusiasm which no less faithfully reflect the national virtues.

FRANCE.—French N. were under very strict laws before the Revolution, nor has the country since ever experienced to the full the blessings of a free press. The oldest paper was the *Mercurie François* (1605-45), a semi-historical compilation. The *Gazette de France* was published from 1631 to 1792. The *Journal de Paris*, 1777-1825, was the first daily political paper. In the memorable year of 1789 a number of journals were started—Marat's famous *Ami du Peuple*, which preached the gospel of Rousseau and sounded the death-knell of Louis XVI.; the *Journal des Débats*, always famed for moderation and ability; and the *Moniteur Universel*, which remained consistently for eighty years the organ of whatever government happened to be in power. Under the Empire only five political journals were permitted in Paris, and a strict censorship was established, which remained in full force till 1821. The liberty of the press again suffered under the Ordinances of 1830, and was fettered still further in 1835. During Louis-Philippe's reign the most popular papers were the *Sicile* and the *Constitutionnel*, which latter had in 1846 a circulation of 180,000, and the *Presse* of Emile de

Girardin, which by reducing its price to forty francs per annum, was the pioneer of cheap journalism. On the establishment of the Empire by Louis Napoleon in 1851, he crushed the opposition press with unparalleled determination. The *Presse*, *Pays*, *Patrie*, *Union*, *National*, *Débats*, *Paris Journal*, *Charivari* (humorous), *Figaro*, *Gaulois*, *Galignani's Messenger* (printed in English), and the *Journal Officiel*, which superseded the *Moniteur Universel* as the government organ in 1869, were among the principal N. of his reign. Rochefort's libellous *Lanterne* (1868) was an extraordinary success. Since 1870 a multitude of N. have sprung up, the *Soir*, *Bien Public*, *Constitution*, &c., and M. Gambetta's *République Française*, which in 1877 received such rough treatment from the Macmahon Government. The journals of Paris numbered 791 in 1875, of which 113 were political.

Germany was early in the field of journalism. The *Relationen* of the 16th c. disseminated records of striking events and extraordinary occurrences throughout the country. The *Frankfurter Oberpostamt Zeitung*, founded in 1616, lasted exactly 250 years (till 1866). In the middle of the 17th c. N. were placed under government censorship, and their number was unimportant, while their contents were little more than official news till the date of the French Revolution. The *Allgemeine Zeitung*, now of Augsburg, started at Tübingen in 1798, has been the most successful German journal, and at the present day holds the leading place for literary excellence, variety of contents, and reliable and extensive correspondence. Under the French rule the national tone disappeared from the German press, and a strict censorship initiated in 1819 impeded its development. Since 1848, and particularly after 1870, there has been a great increase in the number and ability of journals. In March 1872 there were 1743 real N. in the empire, 951 of which were in Prussia. The leading journals of Berlin are the *National Zeitung*, the *Norddeutsche Allgemeine Zeitung*, *Neues Berliner Tageblatt*, *Volks Zeitung*, *Tribüne*, *Post*, &c., and the humorous *Kladderadatsch*. The *Deutscher Reichsanzeiger* is the official gazette. The *Kölnische Zeitung*, *Stettiner Zeitung*, the *Allgemeine Zeitung* of Augsburg before mentioned, and the *Deutsche Allgemeine Zeitung* of Leipzig, are a few of the best provincial journals.

ITALY.—In Italy the press has been comparatively free since 1861, and all the large towns have a number of journals. *L'Italia* is the government mouthpiece for foreign affairs. *Il Diritto* is perhaps the best of the liberal papers. *La Voce della Verità* is the papal organ.

AUSTRIA.—The ablest paper in Austria is the *Neue Freie Presse* (daily). The Viennese press includes the *Wiener Zeitung*, *Deutsche Zeitung*, *Neues Wiener Tageblatt*, and *Fremdenblatt*. The *Bohemia* at Prague, *Ellenör* at Pesth, and *Triester Zeitung* at Trieste may be mentioned.

RUSSIA.—The N. of Russia are almost confined to St. Petersburg, Moscow, Warsaw, Riga, and Odessa. Peter the Great established the first Russian journal at Moscow in 1703. During the reign of Nicholas the *Northern Bee* had the greatest influence. The *Golos* (the Voice) is now the most popular paper in the empire, and during the present war has been the most anti-English in tone. The *Invalide Russe* is the leading military authority, and the *Journal de St. Petersburg* is a semi-official publication, the mouthpiece of the Imperial Foreign Office. Almost every minister of state has his organ. The *Moscow Gazette* is of great political importance and has a circulation of 15,000.

SPAIN AND PORTUGAL.—The press has been uniformly prosecuted in Spain, and there is no country of equal standing in Europe with so few important journals. Satire and humour are greatly aimed at as prominent and attractive features. *El Emparcial*, *El Pueblo*, and *L'Epoca* are the chief dailies of Madrid. N. in Portugal are principally commercial. The *Diário de Lisboa* is one of the best Lisbon papers, the *Diário do Governo* being the official organ.

BELGIUM AND HOLLAND.—Some very influential papers are published in Belgium, including the *Indépendance Belge*, the leading liberal journal, the clerical *L'Étoile Belge*, the official *Echo du Parlement*, *Le Nord*, a Russian organ (Brussels), and the *Journal d'Anvers* (Antwerp). The *Amsterdamsche Courant* and *Handelsblad* (Amsterdam), *Dagblad van Zuidholland*, and *Vaderland* of the Hague are leading journals in Holland. The history of the Dutch press dates from 1623.

SWITZERLAND.—Switzerland has in proportion to size a wonderfully active press, a plethora of local prints being issued in French, German, and Italian. Of some 400 papers the *Journal*

de Genève, *Gazette de Lausanne*, and *Neue Züricher Zeitung* are among those most extensively read.

DENMARK.—About 200 papers are published in this little country. The oldest and most celebrated, *Berlingske Tidende* (founded in 1749), is a semi-official organ.

NORWAY AND SWEDEN.—Among the more prominent papers are *Morgenbladet*, *Aftenbladet*, *Christianiaposten*, *Bergens Tidende* (Bergen), and *Dagens Nyheter* and *Aftenbladet* of Stockholm.

TURKEY.—Such N. as are published in Turkey are mainly issued in Constantinople. *Le Courrier d'Orient*, *Bassiret*, *Stamboul*, and *Levant Herald* (English) may be mentioned.

GREECE.—The principal papers are the *Messenger d'Athènes* and the *Hermopolis* of Syra.

ASIA.—In *China* the *King Chau* (Court Transcripts), known to Europeans as the *Pekin Gazette*, an official compilation of news, is circulated among the officers of state in different parts of the empire. A similar journal exists in Japan. The *Shanghai Herald*, *China Mail* (Hong Kong), and *Japan Herald* (Yokohama), are well-known English N. in that part of the world. The *Friend of India* (Serampore), *Times*, *Telegraph*, and *Gazette* (Bombay), and *Englishman* (Calcutta), are leaders in Anglo-Indian journalism. *Hickings's Gazette* (1781) was the first Anglo-Indian paper. Until 1835 the press in India was under a censorship, and the control of the E. India Company, but in that year all restrictions were removed.

AUSTRALIA has a rising and energetic press, including the *Argus*, *Age*, and *Herald* (Melbourne); the *Herald* and *Empire* (Sydney), &c. In *New Zealand* the *Southern Cross*, *New Zealand Gazette*, &c., are published.

SOUTH AMERICA has a large number of journals, though few are of cosmopolitan importance. Brazil has 60, and Peru 40 dailies.

NORTH AMERICA.—The United States has been more prolific of N. than any other country. The earliest American newspaper, *Public Occurrences both Foreign and Domestick*, was published by B. Harris at Boston, September 25, 1690, but was immediately suppressed. It was followed by the *Boston News Letter*, a weekly paper, 1704-76. The *New York Gazette* (1725) was the first newspaper issued in that city. In 1776, 37 papers were in existence, all of which were weeklies, with the exception of the semi-weekly *Advertiser* of Philadelphia. The *Daily Advertiser*, started at Philadelphia in 1784, was the first daily paper in the U.S. The *Commercial Advertiser*, the oldest of present New York journals, was established in 1797. In the year 1800, the number of N. in the States was 200; in 1828 it had increased to 852. A table is given in Rowell's *American Newspaper Directory* (New York) for 1874, giving the number of N. then published in the States as 678 daily and 5554 weekly, and in British America, 46 daily and 315 weekly. The same work for 1875 gives a list of 506 journals in N. America, with an average circulation each of over 5000, of which 123 (17 daily) were published in the city of New York, 44 (11 daily) in Philadelphia, and 50 (7 daily) in Boston. The great variety of sects in America occasions a vast quantity of religious papers. 337 journals were printed in German, 27 French, 26 Scandinavian, 23 Spanish, 8 Dutch, 2 Italian, 5 Welsh, 4 Bohemian, 2 Polish, and 1 Portuguese in the year 1875. Foremost in popular favour and in circulation in America is the *New York Herald*, established in 1835 by the late J. G. Bennet, as a 2 cents paper. The price was afterwards raised to 4 cents. Under the management of J. G. Bennet, Jr., the present proprietor, the paper has attained a circulation of 65,000 (1875). It is the organ of no political party. No paper in the world surpasses it in enterprise or audacity. The successful mission of H. M. Stanley, at the expense of the *New York Herald*, to look for Dr. Livingstone deserves commemoration. The *New York Tribune* (edited by Horace Greeley 1841-72, circulation 44,000 in 1875) comes next in importance. Under Greeley it was always able, high-toned, and enthusiastic, but not always consistent. It is as vigorous as ever under Mr. Whitelaw Reid, but is no longer a vehicle of the most advanced and the most absurd crotchets. The *New York Times*, the organ of the extreme republicans (founded in 1850, circulation 42,000), the *Sun* (price 2 cents, circulation 119,792), and the *Evening News* (1 cent, circulation 127,360) are among the most popular journals. The *World* (Democratic, 1860) and *Evening Post* (1801) have more literary finish than most of their contemporaries. Mr. W. Cullen Bryant edited the latter paper for many years. The *New*

York Graphic (1873) was the first attempt at a daily illustrated paper. Ten New York papers form the New York Associated Press, which collects news at an annual expense (1875) of about \$1,000,000. *Harper's Weekly* and the *New York Ledger* have each an enormous weekly circulation. The *Nation* is an admirable critical journal, the *Saturday Review* of America. The leading paper of Philadelphia is the *Public Ledger*, started in 1836 at 1 cent. It was the first paper to use the Hoe machine (1844). Its present (1877) proprietor is G. W. Childs, its price 2 cents, and its daily circulation 90,000. Its printing-office is the finest in the U.S. The *Boston Herald* and *San Francisco Chronicle* are important and influential N. The type used in American journals is not so large or so clear as in British papers. In the Southern and Western States the press is still in a very primitive condition, but its progress is only a matter of time. At present the American press faithfully reflects the intellectual condition of the people, that is to say, it is the most energetic but not the most cultivated press in the world. If energy continue, culture will come. The most popular papers in Canada are the *Toronto Globe* and the *Montreal Witness*. 29 out of 75 newspapers published in the Province of Quebec are in the French language.

References.—Besides the works already mentioned see *The Fourth Estate*, by F. Knight Hunt (Lond. 1859), *History of British Journalism*, by A. Andrews (Lond. 1859), and *The Newspaper Press, its Origin, Progress, and Present Condition* (Lond. 1871).

Laws Regarding N. in Great Britain.—The provisions of the law of Copyright (q. v.) apply to articles published in N. They belong to the proprietors, who have paid for them. But if a contribution be gratuitous, probably it will be held to belong to the author. The *Goodwill* (q. v.) of a newspaper is property transmissible to heirs; and if on the dissolution of a partnership carrying on a newspaper, by the death of one of the partners, the surviving partners refuse to buy the deceased's share, then it must be otherwise sold on behalf of his representatives.

New Style. See CALENDAR.

Newt, a name given to various vertebrate animals belonging to the class *Amphibia* (q. v.). The newts are 'tailed' amphibians or *Urodela*—that is, the tail with which the young N. or *tadpole* is provided persists throughout life. In the frogs and toads, on the other hand, it becomes abortive. The newts, like all other amphibians, possess gills in early life. As adult life is attained, the gills are cast off, and these animals, even although inhabiting water, breathe exclusively by lungs. The newts are well-known inhabitants of ponds. The common N. (*Triton cristatus*) is a little lizard-like creature, having a blackish body marked with yellow spots. The male bears a crest along the back. The food consists of worms, the larvæ of insects, &c. Another species is the marbled N. (*Triton marmoratus*) of S. Europe, which has a body olive-brown above with whitish markings. The smooth N. (*Lissotriton punctatus*) is not so exclusively aquatic as the species previously mentioned. It may be found often far removed from water. It has a smooth, non-warty skin, and is smaller than the common N. The colour is brownish-grey above and a bright orange on the under parts, the belly being marked with round black spots. The average length is 3½ inches. The N. is (contrary to popular belief) quite innocuous. It is noted for an extraordinary facility in replacing or reproducing members that have been destroyed.

Newton, a city of Massachusetts, U.S., on the Charles River, 8 miles W. of Boston by rail, contains 27 churches, several libraries, and the large Baptist seminary known as the N. Theological Institution. It has 2 weekly newspapers, and numerous factories. Pop. (1870) 12,825.

Newton, Sir Isaac, was born at Woolsthorpe, 8 miles S. of Grantham, in Lincolnshire, England, December 25, 1642 (old style). He seems to have early displayed a mechanical turn of mind, and after being educated at Grantham school, he was sent to Cambridge, entering Trinity College in 1660. When he first applied himself seriously to the study of mathematics is not known, but there is no question that before the end of 1666 he had discovered the Binomial theorem, established the principles of his method of fluxions, and demonstrated from Kepler's laws the nature of the force which held the planets and sun together. He graduated M.A. in 1667, and succeeded Dr. Barrow as Lucasian Professor of Mathematics in 1669. Before this he had speculated upon the identity of the terrestrial force of gravity

which makes an apple fall to the ground with the force that keeps the moon in its orbit round the earth and the planets in their orbits round the sun—a wrong measurement of the earth being all that prevented him from then establishing the whole dynamical system of the universe. At this time accordingly he discarded his hypothesis without having divulged it to any, and turned his attention to the construction of telescopes. This led to his great discovery of the composite character of white light, the connection between the refractive power and colour, and the explanation of chromatic effects of ordinary refracting telescopes. His attempt to attain achromatic combinations was unsuccessful, owing to a faulty experiment, whereupon he turned to the consideration of reflecting telescopes, a new form of which he proposed and constructed in 1669. His theory of optics, though now disproved, is one of extraordinary subtlety, worthy of the intellect that conceived it. In 1672 N. became a member of the Royal Society. In 1682, when he was attending a meeting of the Royal Society, mention was casually made of Picard's recent measurement of the arc of the meridian. His old speculations regarding the law of gravitation were re-awakened; and with the new value for the earth's radius he renewed his calculations. The agreement between theory and observation was established. A series of papers soon appeared before the Royal Society, which afterwards formed the basis of the famous *Philosophiæ Naturalis Principia Mathematica* (1687). The publication of this work is mainly due to the exertions of Halley, who alone of all Newton's countrymen seems to have recognised the vast importance of the work N. had done. The *Principia* consists of three books. The first, after establishing the fundamental conceptions of dynamics, proceeds with a clearness and conciseness never perhaps equalled to investigate the motion of unresisted bodies, rectilinear, circular, elliptic, cycloidal, and other motions, besides the important subject of attractions. The second book discusses resisted motion, and closely connected therewith the properties of fluids, the theory of wave-motion, and the paths of projectiles. The third book (*De Systemate Mundi*) is a complete statement of the Newtonian doctrine of the universe. The irregularities of planetary motion are recognised and explained, the lunar theory is stated in detail, and methods are given for calculating the paths of planets and comets from observations of position. In the opening sections of the first book, the fundamental principles of the differential calculus are demonstrated by rigid geometry, while in the discussion of the surfaces of equilibrium in a rotating mass of fluid the first step in the history of mathematics is taken into the domain of the calculus of variations. N. was one of the representatives of Cambridge University in the parliaments of 1688-89 and 1703-1705. During the later years of the 17th c. his pecuniary circumstances seem to have been rather straitened, and an accident, in 1692, by which he lost the fruits of twenty years' labour (the story of the dog Diamond is discredited by Brewster), appears to have for a time impaired his intellect. In 1695 he was appointed Warden of the Mint, with a salary of over £500, and in 1699 was promoted to the Mastership. In 1705 he was knighted by Queen Anne, and was annually re-elected President of the Royal Society from 1703 till his death at Kensington, March 20, 1727. The latest edition of the *Principia* is that by Professors Blackburn and Sir W. Thomson (Glasgow, 1871), which follows the text of the second edition by Cotes (1713). Newton's other chief works are *Optics* (1704), *Arithmetica Universalis* (1707), *Analysis per Equationes Numero Terminorum Infinitas* (1711), *De Systemate Mundi* (1728), a popular account of the truths of the third book of the *Principia*, *The Chronology of Ancient Kingdoms Amended* (1728), *Optical Lectures* (1728), *Observations on the Prophecies of Daniel and the Apocalypse of St. John* (1733), *A Method of Fluxions and Analysis by Infinite Series* (1736), besides papers published by the Royal Society, and a quantity of mathematical MS., a list of the contents of which is given in Hutton's *Dictionary*. The work which N. did can never be over-estimated. Like many true geniuses, he was in advance of his time, and recent discoveries have shown this more and more by making intelligible many of his almost prophetic utterances. The controversy with Leibnitz regarding the invention of the fluxional methods, and the quarrel with Flamsteed, the astronomer-royal, are the only episodes that troubled his calm but momentous life. See Brewster's *Life of N.* (1831). N.'s correspondence with Cotes was published by Mr. Eddleston in 1850.

Newton, Rev. John, son of the master of a merchant-ship, was born in London, 24th July 1725, led a wild life in his youth, but was afterwards converted, and having attained a certain knowledge of Latin and Greek, was ordained curate of Olney, Buckinghamshire, in 1764. Here he made the acquaintance of Cowper (q. v.) the poet, over whom he exercised an influence more intense than wholesome. Together they wrote the famous *Olney Hymns*. In 1779 N. was presented to the living of St. Mary-Woolnoth, London. He died 31st December 1807. N. was deeply, not to say darkly, evangelical. The shadow of a libertine youth threw a gloom over his theology. In his views of human depravity we recognise the distorted image of his earlier self; but no man merits blame who, from whatever cause, is deeply impressed with 'the exceeding sinfulness of sin.' N. wrote, among other things, *Cardiphonia, or the Utterance of the Heart; the Messiah, a Series of Sermons*; and a *Narrative of his own Life*.

Newton, Rev. Thomas, an English divine, born at Lichfield, January 1, 1704, and educated at Lichfield grammar-school, Westminster, and Trinity College, Cambridge, was rector of St. Mary le Bow, 1744-61, and bishop of Bristol from the latter year till his death, 14th February 1782. He published a critical edition of Milton's Poetical Works, with a biography, in 1749, but is best known by his popular *Dissertation on the Prophecies* (1754-58). See Memoir prefixed to the second edition of his works, published in 1787.

Newton-Abb'ot, a market town of England, in Devonshire, at the head of the Teign estuary, 16 miles S. of Exeter by rail. The chief buildings are the cruciform church of St. Pauls (1861), the town hall, assembly rooms, and market house. There are breweries, iron-foundries, a tannery, and convenient wharves for the loading of corn, coal, timber, and potter's clay, of which last 6000 tons are sent yearly to Staffordshire. Here William III. published his first proclamation after his landing at Torbay (1688). Pop. (1871) 6082.

Newton-in-Makerfield, a town of England, in Lancashire, 15 miles W. of Manchester by rail, contains two churches, a Roman Catholic chapel (1865), an ancient court-house, market cross, assembly rooms, mechanics' institute, &c. The London and North-Western Company's works for the manufacture of railway trucks employ 800 hands, and there are also an iron foundry, glass works, sugar refinery, paper mills, &c. Pop. (1871) 8244.

Newton-Limavady, a market-town in Ireland, county of Londonderry, on the river Roe, 16 miles E.N.E. of the town of Londonderry by rail. N.-L. has Episcopalian, Roman Catholic, and Presbyterian churches, two banks, some trade in flax, and manufactures of whisky. It occupies the site of a castle of the O'Cahans called in Irish Gael, *Leim-a-madha* ('Dog's Leap'). N. was chartered in the reign of James I. Pop. (1871) 2918.

Newton's Rings, so called from their having been discovered and first discussed by Newton, form a beautiful illustration of the Interference (q. v.) of light. A slightly convex plate of glass is pressed close against the under surface of a plane plate. If the apparatus be now viewed from above in monochromatic light, such as that emitted by sodium burning in a Bunsen flame, a series of concentric rings of alternating light and dark is seen. This is due to the interference of the rays reflected internally from the lower surface of the plane plate with those reflected from the exterior surface of the convex plate. According to the distance between these two surfaces, the one set of rays lags behind the other by one, two, three, or more half-wave lengths. When the difference in phase is one, three, five, or any odd number of half-wave lengths, darkness is the result; but when the difference is any even number of half-wave lengths, the result is increased brightness. When the apparatus is viewed in diffuse daylight, the alternating bands vary through all the tints of the rainbow, on account of the different wave lengths of the different coloured rays, and therefore the correspondingly different conditions necessary for the interference of these various rays. When the plates are sufficiently close, a dark spot forms the centre of the rings, which increases or diminishes in size with a simultaneous expansion or contraction of all the concentric rings as the plates are pressed close together or separated more from each other. The phenomenon evidently gives an easy method of measuring wave-lengths of light.

Newton-Stewart, a town in the S.W. of Scotland, county of Wigton, on the river Cree, 50 miles W.S.W. of Dumfries by the Caledonian Railway. Its chief buildings are the town-house, and the 'Ewart Institute,' a public school under trustees, which has attained some repute as an educational institution. N.-S. has an Established church, a U. P. church, a Roman Catholic chapel, two Free churches, and three branch banks. Pop. (1871) 2873.

Newton-upon-Ayr, a burgh of regality in the county of Ayr, Scotland, on the N. bank of the river Ayr, is united to the town of Ayr by three bridges. It derives its chief importance from its proximity to the harbour. Its principal trade is the export of coal. Ecclesiastically it is noted in Scotland for superior discernment in the selection of parish ministers. Pop. (1871) 4677.

Newtown, a town in New South Wales, forming a suburb of Sydney, but under distinct municipal government. As a place of residence it is much in favour with the Sydney merchants. Pop. (1875) 5570.

Newtown, a town in Wales, county of Montgomery, in a fertile valley on the river Severn and the Montgomery Canal, 13½ miles S.S.W. of Welshpool by rail. It has the ruined church of St. Idloes, a new church (1847), Independent (1877), Baptist, Wesleyan, and other chapels, and two banks. Formerly a small village called Llanfair Ynghedrevain, or St. Mary's, N. has risen rapidly to be the centre of the flannel trade of Montgomery. It has more than fifty factories, chiefly for fine flannels. Leather, beer, delf, and machinery, are also manufactured. Pop. (1871) 5744.

Newtownards, a market-town in Ireland, county of Down, near the head of Strangford Lough, 7 miles W.S.W. of Donaghadee by rail. N. has seven Presbyterian churches and chapels, a Roman Catholic chapel, a Methodist chapel, and a bank. There are manufactures of muslin, linens, and embroidery. N. was chartered under James I. Pop. (1871) 9437.

New-Year's Day fell with the Jews on the 1st Tizri (October); with the Romans on the 1st January; and with the Franks, on 1st March under the Merwings, on the 25th March under the Karolings, on Easter Sunday under the house of Capet, and on 1st January since 1564 (see DATES). The Jewish feast of Trumpets, and the No-Ruz of the Parsees, it was consecrated by the Romans to Janus Bifrons, and was marked by the interchange of presents and good wishes. (Suet. *August*, 57.) The early Church regarded the New-Year's festival as a relic of heathendom, and the Trullanian Synod of Constantinople (692) forbade its observance. Nevertheless, whether as the Feast of the Annunciation (March 25) or of the Circumcision (Jan. 1), the day has for centuries been regarded as a holiday of obligation. Among the Wesleyans it is ushered in by a midnight service termed the 'Watch Night,' and in the Catholic Church by a solemn chanting of the *Te Deum*; while from almost every belfry of England the Old Year is still tolled out, and the New rung in. The Scotch custom of 'first-footing,' and the French *drennes* (Lat. *strenæ*, 'gifts of sweetmeats') are survivals of the ancient festival of Janus. See Brand's *Popular Antiquities* (new ed. Lond. 1876).

New York, the most important of the United States, called 'The Empire State,' and one of the original Confederacy of 1776-88, is bounded N. and N.W. by the Dominion of Canada, from which it is partly separated by St. Lawrence River, Lake Ontario, Niagara River, and Lake Erie, also on the N. by Long Island Sound and the Atlantic; E. by Vermont and Lake Champlain, Massachusetts, Connecticut, N. Y. Bay, and the Atlantic; S. by the Bay, the Atlantic, and the States of New Jersey and Pennsylvania. Area, 45,658 sq. miles; pop. (1875) 4,705,208, of whom 500,000 were coloured and 5000 Indians. The shape of N. Y. is that of a triangle, with its apex towards the ocean. The coast line, however, though only 58 miles in extent, is the most important in the Union, including as it does Manhattan and Long Islands, on which the cities of N. Y. and Brooklyn are built. Besides these and Staten Island, there are hundreds of smaller islands belonging to this State, situated partly in Long Island Sound, partly in the Hudson and St. Lawrence Rivers, and partly in the lakes above named. The surface is agreeably diversified with mountain, valley, and plain, the highest peaks being Mount Marcy or Tahawas (5467 feet), Dix Peak, Mount

MtIntyre, and Sandanoni, all above 5000 feet, in the Clinton Range. The principal rivers are the Hudson, St. Lawrence, Oswego, Genesee, Niagara, and Alleghany. The geology is of a very mixed character, the principal rocks being sandstones, limestones, and slates. The most important minerals are iron, plumbago, lead, and salt, as well as many fine building stones, such as granite, white and coloured marble, and paving-stone. The most of the soil of N. Y. is arable, and some of it very fertile, while the hilly portions afford fine grazing lands, and yield the best butter, milk, and cheese. Till lately, half the area of the State was covered with forests of pine, oak, ash, elm, maple, &c.; but the great demand for timber has within the last few years greatly reduced the forest area. In 1874 the produce of oats was 30,302,000 bushels, of Indian corn, 16,807,000; of wheat, 9,161,000; of barley, 6,463,000; of buckwheat, 2,917,000; of potatoes, 25,423,000; of tobacco, 1,593,000 lbs.; and of hay, 5,291,800 tons. The live-stock comprised 665,800 horses, 669,900 oxen, 1,467,000 milch cows, 1,996,400 sheep—total value, \$153,006,101. In manufacturing industry N. Y. is the first State of the Union. In 1870 the capital invested was \$366,994,320, and the value of annual produce \$785,194,651. The chief manufactures are flour, sugar, tobacco, leather, iron, machinery, and ready-made clothing. There were in 1876, 5525 miles of railway. Albany is the State capital, but the great centre of activity and influence is the city of New York. The principal other towns are Brooklyn, Buffalo, and Rochester. For the history of the early colonisation of N. Y. see under the city. Its first State constitution was adopted in April 20, 1777. The Articles of Confederation for the States were approved by N. Y. in February 1778, and the Constitution ratified by it on July 26, 1788.

New York, the largest and most important commercial city and seaport in the United States, is situated on Manhattan Island, at the mouth of the Hudson or North River, where it joins the strait known as the East River, 18 miles from the Atlantic at Sandy Hook, and 150 miles S. of Albany, the capital of the State. Manhattan Island, separated from the mainland on the E. by Harlem River, on the W. by Spuyten Duyvel Creek, has an area of upwards of 22 sq. miles, being 13½ miles in length, with an average breadth of 1½ miles. Blackwell, Ward, Randall, Bedloe, Ellis, and Governor's islands lying near, contain about 300 acres, and are used for almshouses, penitentiaries, &c.

Streets, Parks, and Public Works.—Excepting the southern end of the city, which is irregularly built, the plan of N. Y. is a model of regularity, with straight avenues 8 miles in length and 100 feet wide, running to the northern end of the island, and traversed at right angles by streets which, designated like the avenues merely by numbers, reach from one side of the island to the other. Broadway, exceptionally possessed of a name, is the most famous of these avenues, and with its 6 miles of shops and hotels is one of the gayest streets in the world. The finest architecturally is Fifth Avenue, where are situated the most superb private houses, churches, and club-houses. The public parks are eighteen in number, the largest of which is the Central Park, 2½ miles long and half a mile wide. It is in the form of a perfect parallelogram, divided into the Upper and Lower Parks by two large reservoirs of water, and is magnificently laid out. Water is supplied to the city from the Croton River, 40 miles distant, by an aqueduct of solid masonry, 8½ feet deep by 7½ feet wide, having a capacity of 106,000,000 gallons a-day. It crosses Harlem River on the High Bridge, a granite structure 1450 feet long, 21 feet wide, and 114 feet high; and is distributed through 350 miles of pipe. Among the great public works of N. Y. may be mentioned the Brooklyn Suspension Bridge. The piers, which are planted on the opposite shores of the East River, are 1620 feet apart, and 280 feet in height; the total length of the bridge, including the approaches, is over a mile. The span of the bridge is 130 feet above the channel of the river, and the roadway includes a railroad track, a carriage-way, and a side-walk. In 1876 it was arranged to construct a new bridge spanning the arms of the East River at Blackwell's Island. The total length of the new bridge when completed will be 10,532 feet. The roadway will be 34 feet wide, comprising a roadway and carriageway.

Public Buildings, Libraries, &c.—The chief public buildings are the City Hall, in the Park, an elegant structure of white marble erected in 1803; the new Courthouse adjoining it, also of marble; the Customhouse, formerly the Merchants'

Exchange, a massive granite edifice, with columns 38 feet high and 4½ feet in diameter; the old Customhouse, now occupied by the Sub-Treasury, a beautiful marble building; the new Post-office, the grandest public structure in the city (1869-75). Specially remarkable for the immense height of its tower is the brick building lately erected for the *N. Y. Tribune* in Printing-House Square. Among others may be mentioned the offices of the Western Union Telegraph Company and of the *Evening Post* in Broadway, and the Grand Central Railroad Depot, the Windsor Hotel, and the Gilsey House. The hotels of N. Y. are the largest in the world. There are 23 libraries, of which the principal is the Astor Library, founded on a bequest of John Jacob Astor, and opened in 1854 with a collection of 70,000 volumes, which had in 1875 increased to 150,306. The only other free library is the Lenox, incorporated 1870, and including, besides the collection of the founder, James Lenox, the largest ever formed of books on early American history, a fine-art gallery and a museum of curiosities. The oldest library in the city is the N. Y. Society Library, organised in 1740, which has 70,000 vols. The N. Y. Historical Society contains, besides 60,000 vols. of books, a large collection of American antiquities, the Abbot Egyptian collection, the Lenox Nineveh marbles, and one of the best art galleries in the country. The library of the Mercantile Literary Association in Astor Place has 158,000 vols. of current literature. Other large special collections are those belonging to the American Geographical Society, the Union and Episcopal Theological Seminaries, the American Institute, the Law Institute, and the Chamber of Commerce. Several fine-art associations exist. The National Academy of Design, instituted in 1826, and the Metropolitan Museum of Art, incorporated in 1870, both contain large and valuable collections.

Churches.—There are in N. Y. 470 congregations, of which 92 are Protestant-Episcopal, 70 Presbyterian, 58 Methodist-Episcopal, 46 Baptist, 40 Roman Catholic, and 27 Jewish. The largest and finest churches architecturally are Trinity, Grace, St. George's, the new Fifth Avenue Presbyterian, the Reformed Collegiate, and the Jewish Synagogue. These, however, will all be exceeded in size and splendour by the new Roman Catholic cathedral in course of erection (1877), which covers an entire block, and is a Gothic structure of white marble.

Schools, Colleges, &c.—Besides 287 public schools, which are under the charge of a Board of Education, there are in N. Y. two important literary colleges. Of these, Columbia College (q. v.) was established in 1753 by royal charter under the name of King's College. The second is the University of the City of N. Y. It has four departments—arts, sciences, medicine, and law. In 1873 there were 33 professors and 373 students. Besides these there are the College of St. Francis Xavier, Manhattan College, and the Reitzers Female College. The chief schools of medicine are the College of Physicians and Surgeons, medical department of Columbia College above mentioned, the Homoeopathic Medical College, the N. Y. Medical College and Hospital for Women, the Eclectic Medical College, the N. Y. College of Dentistry, and the N. Y. Free Medical College for Women. The amount expended on education in 1874 was \$3,808,321.

Charities, Clubs, Theatres, &c.—N. Y. is celebrated for its charities. The municipal institutions of a charitable nature, which number 27, and include hospitals, asylums, almshouses, nurseries, &c., are placed under a board called the Commissioners of Public Charities and Corrections, who expend upwards of \$1,540,000 annually in their maintenance. Among them are an almshouse, hospital for incurables, blind asylum, charity, fever, small-pox, and infants' hospitals, inebriate asylum, lunatic asylum, and epileptic and paralytic hospitals. Commissioners of Emigration have special charge of homeless immigrants arriving in the city. The numerous clubs of various kinds in N. Y., amounting to about 40, form quite a feature in the social life of the city. The most notable of these institutions are the Union, with a full roll of 1000 members, the Union League, with a still larger membership, the New York, Knickerbocker, Travellers', Century, Lotus, and German Clubs, all of them possessing fine buildings. N. Y. has 18 theatres, including 2 German theatres, an opera-house, and circus.

Newspapers, Journals, &c.—In 1875 there were 123 newspapers published in N. Y. Of these 17 are daily. The leading newspapers are the *N. Y. Herald*, the *N. Y. Tribune*, the *Even-*

ing News, the *Sun*, the *World*, the *Times*, and the *Staats Zeitung*. Illustrated papers are *Harper's Weekly*, *Frank Leslie's Illustrated News*, and the *Graphic*. Papers devoted to stories are the *N. Y. Ledger* and the *N. Y. Weekly*. The chief literary and scientific journals are *Scribner's Monthly*, the *New Atlantic Monthly*, *Harper's Monthly*, and the *N. Y. Nation*. See NEWSPAPERS.

Industry, Commerce, &c.—There is scarcely a branch of industry which is not represented to some extent in N. Y. Shipbuilding and the construction of machinery are most actively carried on. The shipbuilding for 1874 comprised 89 sailing and 69 steam vessels, besides 247 barges, with a total tonnage of 64,000 tons. In 1870 there were in all 7624 manufactories of various kinds, employing, besides 1261 steam-engines and 6 water-wheels, 129,577 hands. The total number of entrances of vessels at the port was 6723, with a tonnage of 5,049,618 tons. The total imports of N. Y., through which nearly 60 per cent. of the whole foreign trade of the United States passes, were in 1874 \$395,133,622, the total exports \$340,360,260. Of the former, the principal articles were woven fabrics, sugar, and tea; of the latter, besides the precious metals, petroleum, cotton, and tobacco. In 1876 the total number of British vessels engaged in commerce with N. Y. was 1821, with a total tonnage of 2,149,616 tons. In the direct trade of Great Britain and the British possessions with this port the number of British vessels which entered at this consulate was 1119, and the total tonnage 1,789,937 tons. The population, which in 1731 was only 4622, amounts, according to the census at the end of 1875, to 1,046,037.

History.—Manhattan Island was first settled by the Dutch under Hendrik Christiansen, an agent of the Holland and East India Company. In 1625 the new colony, which consisted of about 250 persons, received the name of New Amsterdam, and was fortified. The population, who carried on a trade in furs, amounted in 1656 to 1000 souls in 130 houses. Eight years later the English took possession of the place, and changed its name to N. Y. The industry and commerce of the colony now made rapid progress, and in the beginning of the 18th c. N. Y. had become the chief market for the products of the northern colonies. After the Declaration of Independence, the town took an immense stride, although about this time it was much ravaged by fire and fever epidemics. In 1785 the first Congress met at N. Y., where in 1789 the solemn inauguration of Washington as President took place. In 1807 Robert Fulton made the first voyage, in a steamboat up the Hudson from N. Y. to Albany, and in 1812 opened the first steamboat route with Brooklyn. Since 1817 N. Y. has been in regular steam communication with Europe. The Erie Canal was completed in 1826. In 1853 the second grand exhibition of the industries of all nations was held here. In August 1858 the successful laying of the Atlantic Cable was celebrated on Sept. 1 by a holiday and a grand public demonstration. On July 12, 1871, a serious riot occurred between the Orangemen, or Protestant Irish, and the Ribbonmen, a Roman Catholic Association, in which many lives were lost, and which had to be suppressed by military force. In 1872 the notorious 'King' swindlers, who had so long controlled the city government, were brought to justice. In 1873 there occurred an unprecedented business panic, having its origin in the unstable basis on which the currency of the country exists, the effects of which are still (1877) felt. See Mrs. Lamb's *History of N. Y.* (New York, 1878).

New Zealand, a group of islands forming a colony of Great Britain, and situated in the S. Pacific between the parallels of 34° and 48° S. lat., and the meridians of 166° and 179° E. long. It consists of two large islands known as the North Island and South or Middle Island, which are separated by Cook Strait (q. v.), and a third one of much smaller size, called Stewart's Island, separated from the South Island by Foveaux Strait (q. v.). The area of the North Island is 44,736 sq. miles; of the South Island, 55,224 sq. miles; and of Stewart's Island, 1300 sq. miles. The neighbouring groups of the Chatham Islands (q. v.) and Auckland Islands (q. v.) are dependencies of N. Z.

N. Z. abounds in evidences of volcanic action, which has not yet ceased, the high mountain Tongariro (6500 feet) being still active, while the district extending from it N.E. nearly to the Bay of Plenty abounds in geysers, solfataras, &c. Earthquakes are not uncommon, especially at Wellington, but the shocks are not severe. N. Z. is a mountainous country, the mountains occupying a tenth part of the N. Island, and four-fifths of the S.

Island. In the former the highest summits are those of the isolated extinct volcanoes, Ruapehu (9100 feet), and Mount Egmont (8300 feet). The S. Island is traversed from N. to S. by the Southern Alps, a range many of whose summits are clad with perpetual snow, and whose culminating point is Mount Cook (13,200 feet). Several minor ranges of considerable altitude cross the island from the Southern Alps eastwards. There are nevertheless several fine plains, the principal in the N. Island being in the districts of Auckland and Hawke's Bay, and in the S. Island in those of Canterbury and Otago. The extensive mountain system gives rise to many large rivers, of which the chief are:—In the N. Island, the Waikato and Wanganui. In the S. Island, the Hurunui, Rangitata, Waitaki, Taieri, Clutha (q. v.), Mataura, Grey, and Buller (q. v.). Owing to the rapidity of their courses, the only rivers to any degree navigable are the Waikato, Clutha, Grey, and Buller. The lakes are numerous, and some of them are of large size. Lake Taupo, in the heart of the N. Island, has an area of 200 sq. miles, and in Otago are the three large lakes Te Anau, Wakatipu, and Wanaka, whose areas are 132, 112, and 75 sq. miles respectively. The coasts of N. Z. contain a number of fine harbours, the principal being those of Auckland, Port Nicholson, Queen Charlotte's Sound, Port Cooper, Akaroa, Otago, and the Bluff. The S.W. coast is indented by a series of sounds closely resembling the fjords of Norway, the mountains rising precipitously from a great depth of water to a height of several thousand feet, and being clad with forests and seamed by waterfalls, the whole forming scenery of the grandest description.

The climate of N. Z. necessarily varies much according to latitude and altitude above the sea level, but as a whole deservedly enjoys a high reputation for salubrity. At the sea-coast frost and snow never continue throughout the day. The mean annual temperature of the N. Island is 57°, and that of the S. Island 52°, that of London being 51°. The annual rainfall varies from the maximum of 119 inches on the W. coast of the S. Island to the minimum of 25 inches on the E. coast of the same island, the average for the entire colony being 54 inches. The healthiness of the climate is largely owing to the strong winds which are everywhere common.

N. Z. possesses magnificent forests, producing excellent timber, of which the best is that of the celebrated Kauri Pine (q. v.). The undergrowth is exceedingly dense. The hills are everywhere covered with abundance of long coarse grass, which affords pasture to immense flocks of sheep; and the Phormium (q. v.), formerly called N. Z. flax, grows wild up to 1500 feet above the sea-level. The indigenous fauna of N. Z. included no mammals save a small species of rat now extinct, and two kinds of bat, besides several species of seals and whales in the adjoining seas, which swarm with fish of fine quality. The avifauna of the country is extremely interesting, including many species not found elsewhere, as well as the singular forms of bird life represented by the Apteryx (q. v.), Dinornis (q. v.), and Notornis (q. v.). Snakes are wholly unknown, and the colony contains no creature more poisonous than the mosquito save a very rare species of spider (*Latrodectus katipo*) whose bite sometimes results fatally.

N. Z. is exceedingly rich in minerals. Gold is found in payable quantities in the districts of Otago, Westland, and Nelson in the S. Island, and Auckland in the N. Island, but for some years gold-mining has been a declining industry. In 1876 the colony exported 318,367 oz. of gold, valued at £1,268,559, and the total quantity exported up to that date since gold was first discovered in 1857 was 8,277,311 oz., of the value of £32,278,114. Of this amount 3,584,179 oz., valued at £14,077,688, were exported from Otago. Silver, copper, lead, antimony, and manganese are also found in the colony, and are beginning to be worked. Iron is abundant, especially in the form of titaniferous iron sand on the sea-shore of Taranaki (N. Island), and in beds of hematite ore near the N.W. extremity of the S. Island, but as yet these riches are practically untouched. Coal is widely distributed, but in many parts is of an inferior brown description. On the W. coast of the S. Island, however, in the basins of the Grey and Buller rivers, coal of the best quality is found in inexhaustible quantities.

Notwithstanding its mineral wealth, N. Z. is still in the main a pastoral and agricultural country. In 1875 there were in the colony 11,705,000 sheep, 495,000 cattle, 124,000 pigs, and 100,000 horses; and in 1876 the export of wool amounted to

54,01,5440 lbs., valued at £3,395,816. In February 1877 there were 2,682,758 acres of land under crop, of which, however, 2,202,644 acres were in sown grasses. The area under cereals was 352,470 acres. The cultivation of wheat for export is rapidly increasing with the spread of railways, and that of oats as rapidly decreasing. The exports of preserved meats and dressed phormium fibre are both much less than they were a few years ago. The total exports of all kinds from N. Z. in 1876 amounted to £5,626,333, and the total imports for the same year to £6,904,889. The revenue for the financial year ending 30th June 1877 was £3,061,594, and the public debt of the colony at the same date was £20,895,311. There were then 212½ miles of railway open for traffic in the N. Island, and 647½ in the S. Island, while 274 miles were in course of construction.

Auckland was the capital of N. Z. until 1865, when the seat of government was removed to Wellington on account of its central position; but Dunedin is much the largest and most important town in the colony. The pop. of N. Z. at the end of 1876 was estimated at 399,075, exclusive of the Maoris (q. v.), or native inhabitants, who numbered (1874) 45,470. N. Z. was discovered and named in 1642 by the Dutch navigator Tasman. It was next visited in 1769 by Captain Cook, who subsequently explored a great part of its shores. In 1814 the Church Missionary Society established a mission station at the Bay of Islands (q. v.), and soon afterwards trade with New South Wales commenced. The first regular settlement was made by the N. Z. Land Company in 1840, and the first governor was appointed in the same year. As settlement progressed, the colony was in course of time divided into a number of different provinces, as follows:—In the North Island—Wellington, founded in 1840 as already stated; Auckland, established by Governor Hobson in the same year; Taranaki, founded by the N. Z. Land Company in 1841; and Hawke's Bay, separated from Wellington in 1858. In the South Island—Nelson, founded by the N. Z. Land Company in 1841; Otago, founded by an association connected with the Free Church of Scotland in 1848; Canterbury, founded in 1850 by an association connected with the Church of England; Marlborough, separated from Nelson in 1860; and Westland, separated from Canterbury (in the first instance as a county) in 1866. Stewart's Island was included in the province of Otago. Each of the provinces had a lieutenant-governor, termed a superintendent, and a Provincial Council, besides sending representatives to the general legislature; but the provincial system was abolished in November 1876, and a system of counties established in its place. The colony is now governed by a governor appointed by the Crown, with a Ministry responsible to the General Assembly or Colonial Parliament, which consists of the Legislative Council and the House of Representatives. The members of the former are nominated, and those of the latter elected by the constituencies. See *The Official Handbook of N. Z.* (Lond. 1875), *The Australian Handbook for 1877* (Lond. 1878), *Transactions of the N. Z. Institute*, vols. 1 to 9 (Well., N. Z., 1869–77), and works enumerated under MAORI.

New Zealand Flax. See PHORMIUM.

Next Friend is in English law the person through whom an infant—that is, a person under the age of 21—sues at law. The father is usually the N. F., but any one may be so whom the Court may consider able to be responsible for costs.

Next of Kin is a legal phrase, denoting those that are nearest to a person in relationship by blood. The wife of a testator is not included in the meaning expressed by this phrase, she not being a blood relation, *non affinis, sed causa affinitatis*.

Ney, Michael, a famous French marshal, was the son of a cooper, and was born at Sarlouis, January 10, 1769. He received a moderate education, acted for two years as a lawyer's clerk, and entered the army, December 6, 1788. By 1794 he had risen to the rank of captain, and had earned for himself the name *Indefatigable*, by his bold assaults upon the Austrians with a corps of 500 men out of the army of the Sambre and Meuse. N. distinguished himself at the siege of Maestricht (November 4, 1794), was severely wounded at Mainz (December 2), took a prominent part in the capture of Altenkirchen (December 16, 1795), and was raised to the position of General of Brigade after the battle of Forchheim (August 8, 1796). Next year he took part in several combats

on the Rhine, and was made prisoner at Steinberg for a few days. In March 1799 he became a General of Division, joined the army of the Danube, and successfully operated at Andelfingen and Winthertthur, where he was wounded. He passed to the Rhine as General-in-Chief of the army, September 17, and at the head of 9000 men he overcame 20,000 peasants under the walls of Frankfurt. Second in command to Moreau (q. v.), he fought at Burkheim, Engen, Moeskirch, Hochstedt, Ingolstadt, Wasserburg, and Hohenlinden. In 1802 he married an intimate friend of Hortense de Beauharnais, and was thereby linked with the fortunes of Napoleon. He received a Marshal's baton in 1804, obtained the Legion of Honour (1805), and was entitled Duke of Elchingen in honour of that victory. The same year he chased the Archduke Johann from the Tyrol, and in 1806 was present at Jena. In 1807 he fought at Deppen and Eylau, and by the end of the campaign had won from the soldiery the title *Brave des Braves*. Against his will he operated in the Spanish campaign of 1808, in 1810 he captured Ciudad-Rodrigo, and conducted a retreat as creditable to his genius as any victory. Not less did he distinguish himself in the Russian war, and for his conduct at Moscow he was created Prince de la Moskowa. During the struggle with the allied troops, N. was constantly under fire, but when Napoleon's abdication was pronounced he rallied to the new government. But his loyalty to the Emperor returned after his escape from Elba, and he fought with him at the battle of Waterloo. N. was shot as a traitor to Louis XVIII. in the garden of the Luxembourg, December 7, 1815. A handsome monument was raised to him (1852) on the spot where he fell. N. was one of the most cool and dashing soldiers of the Revolution, and perhaps the most efficient strategist among the marshals of the empire. He left three sons, who published his *Mémoires* in 1833. See Thiers' *Hist. du Consulat et de l'Empire*.

Ngami ('the waters'), a large lake in S. Africa, situated between 20° 12'—20° 26' S. lat., and 22° 38'—23° 10' E. long. It was first visited by Livingstone and Oswell in 1846, and was more fully explored by Andersson in 1853. It is situated in a table-land 3700 feet above the sea-level, and the country around it is so flat that the rivers at times flow both into and out of the lake. It is fed principally by the Tonku or Tes-ge River, which is supposed to be an anastomosing branch of the Zambesi, and discharges by the Zouga, also an affluent of the latter river. The lake varies in size according to the season, but on an average measures about 50 miles by 7. The shores are low and densely wooded, and that on the N. is bordered by a belt of sand a mile wide. The water is bitter to the taste, but fish nevertheless are plentiful, and the lake and rivers swarm with crocodiles. Hippopotami, elephants, and buffaloes are numerous in the vicinity, though decreasing, and ivory is sent in large quantities to Wal-fisch Bay for shipment to Cape Town. The inhabitants of the region are the Batoana, a tribe of the Bechuans (q. v.). Andersson describes a curious phenomenon in Lake N., the waters of which daily recede and return as in the ocean.

Ngan-hoi, a province in the E. of China, having an area of 54,001 sq. miles, and a pop., according to the last census, of 36,596,988. The capital is *Ngan-King*, on the left bank of the Yang-tse-Kiang, 190 miles S.W. of Nanking. It is noted for its green tea, porcelain, silks, ink, and varnish, and is the commercial depot of a rich mineral district.

Niagara (an Iroquois word, meaning 'thunder of waters'), a river of N. America, which separates the State of New York, U.S., from the province of Ontario, Canada, and flows N. from Lake Erie to Lake Ontario, a distance of 36 miles, making a total descent of 333 feet. In its upper course of 16 miles it is navigable though impeded by many islands, its average depth being 25 feet, and its fall only 20 feet. Below the celebrated Falls it is again navigable from Lewiston to Lake Ontario, a distance of 8 miles, in which its fall is only 2 feet, and its depth varies from 100 to 150 feet. On the Canadian side the Well and Canal connects the navigation of the upper and lower course, which is interrupted by the Rapids and Falls, and the river is here crossed by two suspension bridges, one about 2 miles below the Falls, 245 feet high and 821 long, constructed in 1855, the other within one-eighth of a mile of the Falls, 190 feet high and 1190 long, completed in 1864. At Grand Island, about 10½ miles above the Falls, the river is nearly 3 miles broad, but subsequently it contracts into a narrow current, and for about a mile before it makes the final leap it descends 52 feet in a series of

foaming rapids. Goat Island, with an area of 70 acres and an elevation of 40 feet, hanging on the very brink, separates the river into two cataracts. On the Canadian side is the great Horse-Shoe Fall, 600 yards broad and 150 feet high. The American Fall is 14 feet higher, but has only a breadth of some 220 yards. What makes the Falls unique is the immense volume of the river, some 2 million tons of water being hurled over the ledge every minute, with a roar that fills the air for several miles. After its magnificent leap, the river has a descent of 104 feet in its course to Lewiston (7 miles), flowing through a deep, precipitous gorge, varying in width from 200 to 400 feet, and accessible only by stairways. About 3 miles below the Falls is a violent eddy known as the 'Whirlpool.' The rock on which the cataract pours is the so-called N. limestone, which is so soft as to have been hollowed along the wall of the precipice, from the Canadian shore to Goat Island, into a rough, slippery, pathway, the 'Cave of the Winds,' half subterranean, half submarine. Goat and Bath Islands are reached from the American side by iron frame bridges resting on piers. Professor James Hall made a trigonometrical survey of the Falls in 1842. See Sir Charles Lyell's *Travels in N. America* (1845).

Nias. See PULO-NIAS.

Nibb'y, Antonio, a distinguished antiquary, born at Rome 4th October 1792. At seventeen he was so good a scholar as to become founder of a school of Hellenists. Employed in the Vatican library, he afterwards became secretary to Louis Bonaparte, in 1820 was appointed lecturer on archaeology in the College of Rome, finally holding a similar appointment in the École de France. He died 29th Dec. 1839. Of his numerous works the most important are *La Grecia di Pausania* (1817-18); *Un Viaggio Antiquario ne' Contorni di Roma* (1819); *Le Mura di Roma* (1820); *Elementi di Archeologia* (1828); *Analisi Storico-topografico-antiquaria della Carta dei Dintorni di Roma* (1837-38). See Tipaldo's *Biogr. degli Italiani illustri*, vii.

Nibelungenlied, or **Der Nibelungen Noth**, the national epic of Germany, is preserved to us in numerous MSS. and fragments of MSS., which fall into two principal groups—the first represented by the Hohenems-Iassberg MS., closing with the words 'Daz ist der Nibelunge liet'; the second, or *Vulgata*, with 'Daz ist der Nibelunge nôt.' The story turns first on the murder of Siegfried, the dragon-slayer, invulnerable, like Achilles, save in a single spot, who, having wrested from the unearthly Nibelungen race their hoard of gold and gems, has married Kriemhild, a Burgundian Princess; and secondly on Kriemhild's vengeance for that murder, in which she is aided by Etzel (Attila) and Dietrich of Bern (q. v.), and having accomplished which, she is herself slain. The lamentation for the fallen is expressed in the *Klage*, an inferior continuation of the lay, which seems to have been originally composed in Latin by a priest of the 12th c. Though tournaments and the Mass are mentioned in the N., its general characteristics are purely heathen, dating from a period long antecedent to the introduction of either chivalry or Christianity. It cannot be doubted that it belongs to that common stock of Aryan tradition whence all Epic Poetry (q. v.) sprang, or that in the *Elder Edda* (q. v.) we meet with the self-same tale in all its essential features. But while Dasent regards the *Elder Edda* as 'the far older, simpler, and grander original of the N. of the 13th c.,' German critics have decided that the nomenclature of the Norse Saga, being distinctly German, presupposes an older German form, existing, that is, prior to the 6th c. Composed originally of detached fragments, welded together by succeeding generations, the N. is believed to have been cast in its present form by a minnesinger of the 12th or 13th c., variously stated to have been Wolfram von Eschenbach, Heinrich von Ofterdingen, and Konrad von Würzburg. Certain it is that, whoever was its compiler, he was deeply versed in courtly manners and habits of thought. It was on the people, however, that the lay gained the strongest hold, a fact evinced in the number of its MSS., the frequent emendations in its text, and above all in the host of imitations to which it gave rise, such as the *Lied vom hürnen Seifrid* (13th c.), Hans Sachs' *Tragedia*, and the prose *Volksbuch von Siegfried*. Its ancient popularity, which had slumbered since the Reformation, has been recently revived by Richard Wagner (q. v.) in his trilogy, *Der Ring des Nibelungen* (1870). Brought to light by Bodmer (1751) and Myller (1782), the N. was first critically handled by Lachmann (q. v.), the advocate of the 'Rhapsodist'

theory. His views have been adopted by Müllenhoff (1855), Lillencron (1856), and Pasch (1863); and opposed by Holtzmann (1814), Zarncke (1855), and Fischer (1859). Of translations may be noticed Simrock's (1827), Scherr's (1860), and Bartsch's (1867), and the most recent editions are by Bartsch (Leips. 1875), and Edzardi (Hann. 1875). For a complete bibliography of the subject see H. Fischer's *Die Forschungen über das N. seit K. Lachmann* (Leips. 1874).

Nice'sa, or **Nice**, an ancient city of Bithynia, at the E. point of Lake Ascania, built by Antigonos, son of Philip, in the 4th c. B.C., and named by Perdiccas, general of Alexander the Great, N. in honour of his wife. After the foundation of the Latin empire, N. was from 1206 to 1261 the seat of a Greek empire, founded by Theodore Lascaris. It fell to the Turks in 1330. Isnik, which marks its site, is little more than a heap of ruins. In Church history N. is celebrated as the seat of the first Œcumenical Council (A.D. 325) over which Constantine the Great presided, and in which the doctrines of Arius (q. v.) were condemned. The Seventh Œcumenical (?) Council was also held here, A.D. 787, under the auspices of the Empress Irene, and established image worship. See COUNCIL; ICONOCLASTS; IMAGE WORSHIP; and NICENE CREED.

Nicarag'ua, a republic of Central America, is bounded N. by Honduras, E. by the Caribbean Sea, S. by Costa Rica, and W. by the Pacific. Area, 58,167 sq. miles; estimated pop. 250,000, the great mass of whom are Indians and mestizos. The eastern portion of N. forms the Mosquito Coast (q. v.); the western is traversed by a branch of the Cordilleras and by a volcanic range, running parallel with the Pacific at a distance of 10-20 miles, and rising in Cosequina to 3835 feet. Between these ranges are the Lakes N. and Managua. The chief rivers are the Estero Real, flowing into the Pacific, and the Coco, Escondido, and San Juan into the Caribbean Sea. With a soil of extreme fertility, vast forests of mahogany, rosewood, and dye-woods, magnificent pastures, and abundance of gold, silver, coal, and other minerals, N., under the influence of a bad climate and shameful misgovernment, has left these resources almost wholly undeveloped, and is now in a state of hopeless bankruptcy. In 1874 the revenue was \$595,100 and the expenditure \$758,500, while the public debt was estimated at \$9,500,000. In 1875 there entered and cleared the port of Grey Town or San Juan del Norte, the only harbour of the republic, fourteen vessels of 3560 tons; and the value of the imports was \$126,720, of the exports (india-rubber, specie, coffee, cocoa-nuts, &c.) \$302,723. Managua (q. v.) is the capital. The religion is Roman Catholic; and the executive is vested in a president, elected for four years, the legislative in a Senate of ten, and a House of Representatives of eleven members. Discovered by Gil Gonzalez Davila in 1521, N. broke loose from Spain (1821), and has since been the scene of countless revolutions. In the early part of 1876, a conference that met at Guatemala to confer on a scheme for the union of the five Central American Republics broke up in confusion, and since then N. has been kept on a war footing, a state of siege proclaimed, and all supplies raised by forced loans.—*Lake N.*, in the republic of the same name, is separated from the Pacific by a volcanic range, 48 feet high at its lowest and 4 miles broad at its narrowest point. It stands 134 feet above the Pacific, and 128 feet above the Caribbean Sea, is 140 miles long by 40 broad, and has an average depth of 80 feet. Countless islets, on which idols of black basalt and other Indian antiquities have been discovered, stud the surface of the lake, which has but one outlet, the San Juan del Norte. This river enters the Caribbean Sea after a course of more than 100 miles, the average depth of its channel being 17 feet, and forms the basis of a projected ship-canal, to unite the Pacific and Atlantic Oceans, the length of which would be 181 miles, and the estimated cost \$65,722,000.

Nicas'tro, a town of S. Italy, province of Catanzaro, 28 miles S. of Cosenza, is the seat of a bishop, and has numerous churches, an episcopal palace, and a ruined castle, in which Friedrich II. imprisoned his eldest son Heinrich (1235). N. is the trade-centre of all the smaller communes on the Gulf of St. Eufemia. Pop. (1874) 13,181.

Nic'ola, **Pisa'no**, was born at Pisa (as his name indicates) about the beginning of the 13th c. All we know of him is derived from a couple of inscriptions, a few contracts, and a legen-

dary *Life* by Vasari. A few ancient sarcophagi in his native town seem first to have led him to a study of the antique, the spirit of which he taught the Italian artist to blend with his own observations of nature. His first masterpiece was the 'Bologna Urn' (1231) ornamented in bas-relief of such dramatic force and noble proportions that he was called 'Niccola of the Urn.' In 1231 he visited Padua, where he designed the magnificent basilica of St. Antonio, only finished in 1407. Venice obtained from him the beautiful 'Church of the Frari' (1250), Florence that of 'Santa-Trinita'; and he designed 'San Lorenzo' at Naples. N. added to the triumphs of his 'Urn' by his 'Deposition from the Cross' (1235, some say 1237), a high-relief, placed over a door of St. Martino at Lucca. About 1260 he executed his 'Pisan Pulpit,' a hexagon of marble supported on nine columns, the sides covered with mingled bas-relief and detached statuary, the whole distinguished by the most marvellous freedom of design and masterliness of execution. It is not to be wondered at that N., struggling to embody Christian ideas in the forms of ancient art, while he gained breadth and force, should lose the subtle qualities of beauty. His heads are often disproportionate to the bodies, and his grouping is generally crowded and clumsy. His pulpit in the Baptistry of Pisa was followed by a similar one at Siena. The market-place fountain of Perugia, and the shrine of St. Dominic at Bologna are also specimens of his work. He died about 1273. N. was the Phidias of Italy—the father of Renaissance art. His son Giovanni, Andrea Pisano, and the numerous pupils who had worked for him wherever he went, extended his principles, seizing not only upon such assistance as the antique lent them, but welcoming eagerly the noble Gothic architecture which had just then accomplished its journey from the dim North. An exultant eclecticism soon sprang up in art; and almost ere the bones of the master were cold, such men as Orcagna, Donatello, Ghiberti, Brunelleschi, Michael-Angelo, had travelled far on the road he opened for them. See Lord Lyndsay's *Sketches of the History of Fine Arts*, vol. ii., Ruskin's *Val d'Arno* (1874), and Symonds' *Renaissance—The Fine Arts* (1877).

Niccoli'ni, **Giovanni Battista**, was born of noble family at San Giuliano, near Pisa, 31st October 1785. He became professor of history and mythology at the Florence Academy of Fine Arts, acting also as its librarian. In 1804 appeared his poem *La Pesti di Livorno*. N. subsequently wrote the frigidly classical *Polissene*, *Medea*, *Ino e Temisto*, *Edipo*, *I sette a Tebe*, *Matilda* (1815), an effort in the direction of the Romantic school, *Antonio Foscari* (1827), for inherently dramatic interest the best of his works, *Lodovico Sforza*, *Rosamonda d'Inghilterra*, *Beatrice Cenci*, *Agamemnone*, *Arnaldo da Brescia*, *Filippo Strozzi*. He died at Florence, 24th September 1861. His most successful drama, *Nabucco*, portrayed the story of Napoleon's downfall, with fictitious names. N., like his French contemporary Delavigne, gained the public ear mainly by the political sentiments freely expressed in all his pieces. His admirers hoped for a national poet in him, but nearly all he wrote is dead already. The best collection of his tragedies is that in 2 vols. (Capolago, 1835.) Professor Corrado Gargioli of Milan began in 1862 a complete edition of N.'s *Opere*. See the *Cornhill* (vol. x. p. 683).

Nice (It. *Nizza*), capital of the department of Alpes-Maritimes, France, beautifully situated at the foot of the Alps, at the mouth and on both sides of the Paglione, 14 miles W.S.W. of the Italian frontier, and 100 E.N.E. of Marseille by rail. The broad stony bed of the Paglione or Paillon, a small stream frequently dried up, is lined by handsome quays and crossed by several bridges. To the N.E. of the town rises the Castle Hill, 320 feet high, crowned by the ruins of a castle destroyed by the Duke of Berwick in 1706. The hill is now laid out in beautiful grounds, where palms, oranges, cypresses, and aloes grow profusely. N. has a Gothic church of Notre Dame, a marble cross commemorating the meeting of Karl V. and François I. in 1538, a square formed by covering in the Paglione between the bridges Vieux and Neuf, and ornamented by bronze statues of Massena (1867), a town library of 40,000 vols., &c. The Promenade des Anglais, adjoining the Jardin Public on the W., was laid out by English residents in 1822-24, and greatly extended in 1862. N. is the winter rendezvous of invalids and others from all parts of Europe, especially from England, Germany, and Russia. The town is almost deserted in summer. The mean temperature in January and February is 47° F., in March 52°, in April 58°. Frost is

rare, and the Mistral, or N.W. wind, the scourge of Provence, is intercepted by the Montagnes de l'Estérel and du Var. The harbour only admits small vessels, those of larger tonnage entering the bay of Villafranca. There is considerable trade in wine, oil, hemp, silk, fruits, and essences. Pop. (1872) 52,377. N., anciently *Nicæa*, was founded by the Greeks of Marseille in the 5th c. B.C. Included in the county of Provence till 1388, and later in the duchy of Savoy, it was occupied by the French in 1792, restored to Sardinia in 1814, and finally annexed to France along with Savoy in 1860. The natives speak a mixed Provençal and Italian dialect. See Tisserand, *Histoire Civile et Religieuse de la Cité de Nice* (Nizza, 1862).

Nicene Creed is so called from having been put forth by the Council of *Nicæa* (325), although not in its present form. The creed adopted by that Council consisted of the ancient creed of Cæsarea, with the addition of the phrase of *one substance with the Father*, to meet the heresy of Arius (q. v.), and ended with *and in the Holy Ghost*. The final clauses were added by the Council of Constantinople (381). The insertion of the term *Filioque* (q. v.) by the Council of Toledo (589), led to the schism between the Eastern and Western Churches, which has continued from the 9th c. to the present time. The N. C., which had previously been the baptismal Confession of Faith, was embodied in the Liturgy by Peter Fullo, Bishop of Antioch, 471, and by the Patriarch of Constantinople in 511. See Canon Swainson's *Nicene and Apostles' Creeds* (Lond. 1875).

Nicephorus, born at Constantinople in 758, held the post of *notarius* to Constantine VI. (780-797), opposed the iconoclasts at the second Council of Nicæa (787), and was raised to the patriarchate (806). Deposed by Leo the Armenian for his opposition to the edict against images (815), he retired to the convent of St. Theodore, on one of the islands of the Propontis, and died there June 2, 1828. N. was one of the ablest of the Byzantine historians, his chief works—all in Greek—being *Breviarium Historicum*, a history of Constantinople from 602 to 770 (Par. 1616); *Chronologia Compendiaria* (Par. 1573); and *Indiculus Librorum Sacrorum* (Par. 1609).—**N. Callistus Xanthopoulos**, born towards the close of the 13th c., and died about 1350, was the author of an *Historia Ecclesiastica* (Par. 1630), which won for him the title of *Thucydides Ecclesiasticus*. He wrote nine other separate works, besides hymns, sermons, epistles, &c.

Nicetas Acominatus or **Choniates**, a Byzantine historian, born at Chonæ (*Colosse*) in Phrygia, about 1150, was appointed governor of Philippopolis by Isaac II. (1189), and later held the offices of *logotheta* and *prefectus sacri cubiculi*, with the title of senator. He fled from the sack of Constantinople by the Latins (1204) to the court of Theodore Lascaris at Nicæa, where he died about 1216. N.'s *Historia*, embracing in twenty-one books the period 1118-1206, was published by Wolf (Basel, 1557) and Becker (Bonn, 1835); his *Narratio de Statu quo Franci destruxerunt*, by Wilken (Leips. 1830).

Niche (Fr. *niche*; It. *nicchia*), a recess in a wall for a statue or other erect monument. Niches, in Norman architecture, are usually shallow and square; in Early English they are deeper and more ornamental. In Early French buildings they are sometimes formed at the set-offs of buttresses, three sides being open, and the canopy supported by slender shafts.

Nichol, John Fringle, an eminent astronomer, was born at Brechin, in Forfarshire, 13th January 1804, studied at King's College, Aberdeen, and after some years spent as a schoolmaster in Hawick, Cupar-Fife, and Montrose, where he won great popularity by his brilliant lectures on astronomy and natural philosophy, was appointed in 1836 professor of the former subject in Glasgow university. Here he spent the remainder of his life. It was mainly by his exertions that the fine observatory in Glasgow was built. No Scottish professor was ever more sincerely loved and admired by his fellow-citizens than N. The chaste and lofty eloquence with which he expatiated on the wonders of his favourite science is still remembered in the West of Scotland; his generous sympathy with youthful ambition endeared him to all the liberal minds of the university. N. died at Rothesay 19th September 1859. His principal works are *View of the Architecture of the Heavens* (Edin. 1837), *The Solar System* (Edin. 1842), *The Planet Neptune* (Edin. 1848), *The Stellar Universe* (Edin. 1848), *The Planetary System* (Edin. 1851), and *The Cyclopedia of the Physical Sciences* (Edin. 1857; 2d ed. 1860).—**John N.**; son

of the preceding, was born at Montrose, 8th September 1833, studied with distinction at Glasgow University and Balliol College, Oxford, where he graduated with first class honours in classics and philosophy in 1859. In 1861 he was appointed Professor of English Literature in Glasgow University, an office which he still (1878) holds. In 1873 he received from the University of St. Andrews the degree of LL.D. Besides contributing to the *Westminster* and other reviews, N. has written a historical drama, *Hannibal* (1872), marked by great beauty and terseness of dialogue, a genuinely poetical spirit, and a distinct power of dramatic conception.

Nicholas, the name of six Popes.—**N. I.**, called 'the Great,' a Roman by birth, was Pope from 858 to his death (13th Nov. 867). His strength of mind and purity of morals fitted him for being the founder of the supremacy of the Papal See, which before N.'s time was wholly dependent upon the Emperors. He successfully interfered in the controversies of the German Church, and humiliated, after a long struggle, the powerful Archbishop Hincmar (q. v.) of Rheims, whose aim was to establish a national church independent of the Pope. This victory was gained by an appeal to the spurious 'Isidorian Decretals' (q. v.). The Frankish King Lothar II., who, contrary to the civil law, but aided by venal bishops, had put away his wife Thietberga to marry his mistress Waldrade, was forced by N. to submit to penance and the reinstatement of his queen. N.'s strife with the Patriarch Photius (q. v.) resulted in their excommunicating one another, and widening the breach between the East and West, but gained over the Bulgarians to the Romish Church.—**N. II.**, formerly Bishop of Florence, was Pope from 1058 to June 24, 1061. He ruled under the influence of Hildebrand, opposing Berengarius (q. v.), of Tours and establishing a new law for papal elections, which placed the choice in the hands of the cardinals.—**N. III.** (1277-22d August 1280) obtained from the Emperor Rudolf of Hapsburg all imperial rights over the Exarchate (q. v.).—**N. IV.** (1288-14th April 1292) strove in vain to stir up a new crusade.—**N. (V.)** was in 1328 set up by Ludwig of Bavaria as anti-pope to John XXII., but in 1330 was delivered up to the latter, who kept him in prison till his death (1333).—**N. V.** (1447-55), properly Tomaso di Sarzano (his mother's home), was born at Pisa in 1398, and ascended the papal chair, 7th March 1447. N. strove to increase the prestige of the papacy, weakened through the influence of the reforming Councils of Constance and Basel. After the capture of Constantinople by the Turks, which he had struggled in vain to avert, he showed the greatest liberality to the learned Greeks exiled by that disaster. With a collection of 5000 MSS. N. practically laid the foundation of the Vatican Library. On the 17th of February 1448, he concluded the so-called Aschaffenburg or Vienna Concordat with Friedrich III.

Nicholas, St., the patron of children and sailors, and also the national saint of Russia, a native of Patara in Lycia, as Bishop of Myra was imprisoned in the persecution of Diocletian, opposed the Arians at the Council of Nicæa (325), and died in 342. His relics were translated to Bari in Apulia by Robert Guiscard, 9th May 1087. From his commemoration falling on 6th November, and from the legend of his dowering three poor maidens by leaving money on their window-sill, N. (or Santa Claus, as he is called in Holland) has long been regarded as the bearer of Christmas presents; and Dutch and American children still put out a shoe or stocking, expecting the saint to fill it during the night. In England his festival was celebrated by the installation of a Boy Bishop (q. v.).

Nicholas of Guildford, the author of a bright and picturesque poem, called *the Owl* and *the Nightingale*. It is a fine specimen of Transition English, written in the dialect of the south of England, but free from broad provincialisms. Though composed in the rhymed octo-syllabic verse of the French Romances, it is a genuine English work, not more than twenty words being of French origin in the whole 1792 lines of which the piece consists. It has been assigned on internal evidence to the reign of Henry III., and is certainly not of later origin. The poem was edited for the Percy Society by Thomas Wright, M.A., in 1843.

Nicholas Paulovitch, Emperor of all the Russias, born 6th July 1796, in the castle of Gatchina, near St. Petersburg, was the third son of the Emperor Paul I. and the Princess Sophie of Württemberg. From his youth he was serious, re-

served, even unsocial, but deeply interested in military affairs. During the reign of his eldest brother Alexander, he remained without influence, stayed for some time in England, and after his marriage (1817) with Charlotte of Prussia, lived in retirement at St. Petersburg. His elder brother, Constantine, who resided as governor at Warsaw, had in 1822 resigned his birthright, yet, on the death of Alexander, N. caused him to be proclaimed (1st December 1825), and only after a second refusal took the crown himself (26th December). He had first to combat a military insurrection in the capital, due to a secret league under Prince Trubetskoi. Murderous artillery-fire, unsparing execution and banishment, quickly cleared his path. N.'s efforts to root out bribery and fraud were less successful, yet the so-called 'Radical Reform,' which established throughout the empire the Russian language, religion, and law, doomed the influence of French culture and policy. At the head of a well-organised military despotism he decided disputes in two continents. In 1828, through Paskievitch, at the Peace of Turkmanchai, he extorted from Persia, which had incautiously made war upon him, Erivan and Nakhichevan. His active measures against Turkey gained Greece to his interest, and by the Peace of Adrianople (1829) he obtained the islands at the mouth of the Danube and on the E. coast of the Black Sea, and secured the partial independence of the Danubian principalities. When the Poles rose for freedom in 1830, his Generals Diebitch and Paskievitch overpowered them, and N. punished them with the severest cruelty, removing the last shadow of their independence by the 'Organic Statute' of 1832. To destroy the influence of the Catholic Church he broke (1839) the 'Union' which had previously bound the Greek Catholics in Lithuania to the Pope, and brought the congregations over to the State Church. He showed the same zeal in relation to the Lutherans of the Baltic governments. After the July Revolution of 1848 he took a decided part against the movement for freedom throughout Europe, and on the 26th March issued an appeal to the people to hold fast by 'the Faith, the Emperor, and Holy Russia,' upbraiding the 'heathens' and 'spirits of sedition.' In July and August 1848, his troops had supported Prince Bibasco in Wallachia, and in May 1849 Paskievitch entered Hungary and compelled Görgei to capitulate at Vilagos (13th August). In the dispute between Austria and Prussia for the direction of Germany, N. took the reactionary side, and in the Schleswig-Holstein question he supported Denmark. He had now an extraordinary influence as the 'maintainer of order' in Europe, and believed himself able to carry out his favourite project of expelling the 'Turks, and seizing the inheritance of the 'sick man.' His arrogance led to the Crimean War, and brought against him England, France, and Sardinia. Repeated reverses, and the humiliation of seeing his greatest effort frustrated, broke his strength, and he died, 18th February 1855, after enjoining the arming of the whole people as a last resource. With him fell the last bulwark of absolutism in Europe. Three sons survived him, Alexander II. (q. v.), his successor, Constantine (q. v.), Michael (born 1832); and two daughters, Maria (born 1819, married in 1839 to Duke Maximilian of Leuchtenberg, who died in 1852, again married in 1856 to Count Gregor Stroganoff), and Olga, Queen of Württemberg (born 1822).

Nichols, John, F.S.A., born at Islington, 2d February 1745, was the apprentice and successor of William Bowyer, and, during a busy life of authorship, edited the *Gentleman's Magazine* from 1778 till his death, which occurred 26th November 1826. Of the sixty-seven works of which he was either author or editor, the chief are a collection of *Miscellaneous Poems with Historical and Biographical Notes* (8 vols. 1780-82); *Biographical and Literary Anecdotes of William Bowyer, F.S.A., and of many of his learned Friends* (1782), a work recast and extended under the title of *Literary Anecdotes of the Eighteenth Century* (9 vols. 1812-15), and continued, with the aid of his son, in *Illustrations of Literary History* (8 vols. 1817-58); and *The History and Antiquities of Leicester* in four splendid folio vols. (1795-1815). See A. Chalmers's *Memoirs of J. N.* (London, 1826).—**John Bowyer N.**, son of the preceding, was born in London, 15th July 1779, educated at St. Paul's School in 1796, joined his father in business, and was sole proprietor of the *Gentleman's Magazine* from 1833 till 1856. From his press have issued many of the noblest specimens of English typography—e.g., Ormerod's *Cheshire*, Clutterbuck's *Herford-*

shire, Surtees' *Durham*, Hoare's *S. Wills*, Whitaker's *Histories of Whalley and Craven*, and Dallaway's *Rape of Arundel*. Among his own writings are a *Brief Account of the Guildhall and Anecdotes of Hogarth* (1833), and *Historical Notices of Font-hill Abbey* (1836). N. died at Ealing, Middlesex, 19th October 1863.—**John Gough N.**, son of the preceding, was born in 1806, and was long editor of the *Gentleman's Magazine*, which ceased to be the property of the Nichols family in 1856. N. was one of the founders of the Camden Society, and edited several important works issued by it and by the Roxburghe Club, &c. He died at Holmwood, near Dorking, 13th November 1873.

Nicholson, John, one of the most ardent of the heroes of the Indian Mutiny, was the son of an Irish physician, and was born at Dublin in 1821. At the age of fifteen he was appointed a cadet in the Bengal Infantry, whither three of his brothers followed. He was taken prisoner in the disastrous Afghan campaign of 1842, and served in the first Sikh War of 1846; but henceforward he entered the political branch of the service (a mixture of the diplomatic and the administrative). In this capacity he was with the army during the second Sikh War of 1848, and subsequently became one of the lieutenants of the two Lawrences in the government of the Punjab. In 1850, while on furlough in Europe, he was involved in an attempt to rescue Kossuth, the Hungarian patriot, from a Turkish fortress. In his own district he was worshipped as a god; and, sorely against his will, he became the *guru* of a sect of 'Nikkul Scyns.' In 1857, at the outbreak of the Mutiny, his advice and prompt action contributed more than the conduct of any single man to preserve the Punjab. He disarmed the mutineers, and hunted down those who would not surrender. Appointed to the command of the Punjab movable column, his arrival gave new strength to the exhausted British force outside Delhi. He won the battle of Nujafgurh, and fell while leading the storming party at the Cabul gate on the 14th September 1857. See *Lives of Indian Officers*, vol. ii., by Sir J. W. Kaye (London, 1867).

Nicias, a distinguished Athenian general and statesman during the Peloponnesian War, was the son of Niceratus, a lessee of silver mines at Laurium. He inherited his father's fortune, which was estimated at 100 talents. Being thus naturally associated with the aristocratic party, he came forward after the death of Pericles as the opponent of the demagogue Cleon. N. gained numerous successes as a general by caution and wariness rather than by military genius or dash. In 427 B.C. he took the island of Minoa; in 426 B.C. ravaged the island of Melos and the coast of Locris; in 425 B.C., compelled the surrender of Sphacteria by the Spartans, and defeated the Corinthians; in 424 B.C. captured the island of Cythera, ravaged the Laconian coast, and took Thyrea. In 423 B.C., in conjunction with Nicostratus, he took Mende and blockaded Scione. On the death of Cleon N. endeavoured to bring about a peace with Sparta, which he accomplished 421 B.C. This is known as the *Peace of N.* In 415 B.C. he was appointed along with Alcibiades and Lamachus to the command of a great naval expedition to Sicily. Success at first seemed to favour the Athenians, but eventually they were signally defeated, and N. being compelled to surrender was put to death 413 B.C. See Plut. *Nicias*; *Thuc.* vi. and vii., and *The Histories of Greece* by Grote and Thirlwall.

Nickel (symbol Ni, atomic weight 59) is a greyish-white metal, occurring associated with cobalt in its ores, and resembling this metal in its general properties. One of the principal ores is *Kupfernickel*, from which the name comes, and which was so-named by the German miners because it was liable to being mistaken for copper ore. Its constitution is given by the formula Ni As. *N. Glance* (Ni As₂-Ni S₂) and *Arsenical N.* (Ni As₃) are other ores—the latter corresponding to the tin-white cobalt. Like cobalt, N. may be obtained by igniting the oxalate. Ordinarily, however, the metal is extracted from the *spieß* formed in the preparation of cobalt, the oxide of N. yielding N. and carbon when strongly heated in contact with carbon. There are two oxides, the protoxide (NiO) and Sesquioxide (Ni₂O₃), the former of which is alone of any importance, forming salts, one of whose distinguishing features is their beautiful emerald-green colour when hydrated. When the solution of a soluble salt is treated with nitric acid, the oxide of N. is precipitated. The most important of the N. salts is the sulphate (NiSO₄·7H₂O), from which the oxalate, valuable as a convenient

source of the metal, is produced by the action of oxalic acid. The sulphate crystallises in beautiful green prismatic crystals, and forms double salts with potassium and ammonium sulphates. The carbonate (Ni Co_3) is produced in a hydrated condition by mixing together solutions of N. sulphate or chloride and sodium carbonate, and is readily decomposed by heat. The chloride (Ni Cl_2) is easily prepared by the action of hydrochloric acid upon the oxide or carbonate. It is green in solution, but yellow when anhydrous. The chief use of N. in the arts is in the preparation of German silver, which contains 50, 30, and 20 per cent. of copper, zinc, and N. respectively. N. is strongly magnetic, losing this property, however, when heated to 350°C .

Medicinal Properties of N.—The sulphate of N. is prescribed in cases of chlorosis and severe headache, in doses of from $\frac{1}{2}$ to 1 grain, two or three times a day. N. is best given on a full stomach, as, otherwise, it is apt to produce nausea.

Nicksies', or Nikschitzj', a fortress and capital of a district of the same name, Herzegovina, near the N. frontier of Montenegro, and 34 miles N.E. of Cattaro, was held by the Turks during the late insurrection in Herzegovina, but capitulated to the Montenegrins, 8th September 1877.

Nicobar Islands, a group of islands in the Bay of Bengal, due S. from the Andamans, and midway between Ceylon and the Malay Peninsula. The three largest are called Sambelong, Carnicobar, and Nancowry. The N. I. seem to be of volcanic formation, and are fringed with coral reefs. From 1756 Denmark claimed sovereignty over them, but in 1848 surrendered her claims to the British. The inhabitants, who are of Malayan origin and about 8000 in number, live mainly on the produce of the cocoa-nut palm. They have an evil reputation for their treatment of shipwrecked mariners. In 1872-73 their trade with India showed an import of £426, and an export of £395. At Camorta, the chief place, there is a penal settlement in connection with Port Blair in the Andamans. There are about 240 convicts, but the site is unhealthy, and escapes are numerous.

Nic'ol, Erskine, R.S.A., was born at Leith in 1825, received his art education at the Edinburgh Academy, and in 1846 went to Ireland, where he resided for several years. After exhibiting pictures for some time in Edinburgh, and becoming a member of the Royal Scottish Academy, he proceeded to London in 1862, and was elected A.R.A. in 1866. His reputation is based on his masterly treatment of humorous Irish subjects, and on the masculine breath of his painting, which, though it bears the signs of an impetuous brush, is free from the affectation of coarseness. Among his best works are 'Renewal of the Lease Refused' (1863), 'Among the Old Masters' (1864), and 'A Deputation' (1865), 'Paying the Rent,' and 'Both Puzzled' (1866). N. is also favourably known as a painter in water-colours.

Nic'olai, Christoph Friedrich, a German publisher and the friend of Lessing, was born at Berlin 18th March 1733, and entered his father's business in 1759. He threw himself ardently into the literary struggles of the time, declaiming against philosophy as represented by Kant and Fichte, and attempting to ridicule Goethe in his *Freuden des jungen Werther* (1775) and *Geschichte eines dicken Mannes* (1794). He did far more for literature, however, as a publisher than as a writer. With Moses Mendelssohn he founded the *Bibliothek der schönen Wissenschaften* (1757). He also started the *Literatur-Briefe* (24 vols. 1759-66), to which Lessing contributed; and the *Allgemeine Deutsche Bibliothek* (106 vols. 1765-98). N. also wrote *Reise durch Deutschland* (1783-96); *Anecdotes von Friedrich II.* (1788-92), and a host of romances, essays, and biographies. He died 8th January 1811. See *N.'s Leben und Literarischer Nachlass*, edited by Göckingk (Berl. 1820).—**Karl Otto Ehrenfried N.,** a German composer, was born in Königsberg, June 9, 1810. Appointed organist to a chapel at Rome in 1834, he diligently studied the works of the old Italian masters under Balini. He was director of the orchestra at the Imperial Opera, Vienna, during 1839, after which he produced the operas *Enrico II.* at Trieste, *Il Templario* at Turin (1840), and *Il Proscritto* at Milan (1841). His most famous work, *Die Lustigen Weiber von Windsor*, was brought out in 1848 at Berlin, where he died, May 10, 1849. In opera N. was a follower of Rossini, his style being fresh and melodious, without possessing striking originality. He composed a number of works for the pianoforte, a Requiem, a Te Deum, &c. His well-selected

collection of ancient Italian MS. music was purchased after his death for the Royal Library, Berlin.

Nic'olas, Sir Harris Nicholas, was born in Cornwall, March 10, 1799, entered the navy, and rose to the rank of lieutenant (1815), but quitting the service on the close of the war, was called to the bar (1825), and thenceforward devoted himself to historical and antiquarian research. He was created a knight of the Guelphic Order (1831) and Chancellor of the Ionian Order of St. Michael and St. George (1832), and died at Cape Curé, near Boulogne, August 3, 1848. N.'s works are marked by singular industry and critical acumen, but also by an acrimony which embroiled him in frequent literary squabbles. The principal are—*Notitia Historica* (1824), *Scrope and Grosvenor Controversy* (1832), *Chronology of History* (1835), *History of the Orders of Knighthood* (4 vols. 1841-42), *Despatches of Lord Nelson* (7 vols. 1844), and an unfinished *History of the British Navy* (2 vols. 1847).

Nic'oll, Robert, a Scottish poet and journalist, was the son of a farmer, and was born in the parish of Auchtergaven, Perthshire, 7th January 1814. Misfortunes occasioned by his own generosity reduced the father to the position of a day-labourer, and N.'s youth was spent in hard toil. In spite of poverty and its accompanying disadvantages, the pure ardour of genius carried him victoriously forward. With the 'fee' he won as a herd-laddie he went to school in winter. By a study of the best English authors he gave himself the truest culture a man can obtain. After making the acquaintance of Robert Chambers, Mr. Johnstone, Mr. Tait, and other persons connected with literature, he opened a circulating library in Dundee in 1835, and in the following year was appointed editor of the *Leeds Times*. Here he fought the battle of Radicalism with an energy far beyond his strength. Attacked with consumption, he was in a year forced to abandon his post. Returning to his native country, he died at Leith in December 1837. During his brief career he wrote a number of lyrics both in English and in his native Doric, all of which are genuine, and some of rare beauty and humanity. *Bonnie Bessie Lee* is perhaps his sweetest lilt. The latest and best edition of his poems, with a touching memoir of the author, was published in 1877 by Alexander Gardiner, Paisley. The memory of this pure and eager spirit is justly dear to his countrymen.

Nic'olo, a variety of onyx, with parallel bands of a black or deep-brown and a bluish-white colour, found chiefly in Bohemia. It was much used by the Romans in gem-engraving.

Nicomedeia, the capital of Bithynia, on the N.E. coast of the Bay of Astacus, was built by Nicomedes I. 264 B.C. In a short time it became one of the greatest and most important of ancient cities, and for more than six centuries continued to flourish. Under the Empire N. was the residence of Diocletian and Constantine when they were engaged in war against the Eastern nations. Earthquakes were frequent in its neighbourhood; but N., though it suffered greatly therefrom on several occasions, was, by imperial munificence, always restored. N. was the birthplace of Arrian, the historian of Alexander the Great, and the scene of the last hours of the great Carthaginian general, Hannibal. At his villa of Ancyron, close by the city, Constantine died, May 22, 337 A.D. The modern *Ismit*, which contains many interesting remains of antiquity, occupies the site of ancient N.

Nicop'oli or Nicop'olis, a fortified town in Bulgaria, Turkey, on the right bank of the Danube, opposite Turnu Maurelli, 20 miles W. of Sistova and 25 N.N.E. of Plevna. It stands on a height, and is defended by a castle and by ramparts mounting large guns. Here the Turks, led by Bajazet I., defeated the Hungarians under Sigismund, September 28, 1396. On July 16, 1877, it surrendered to the Russians, the Turkish garrison (6000) becoming prisoners of war. Pop. 5600, comprising Bulgarians, Wallachs, and Jews. At some distance, near the village Eski-Nikup, are the ruins of the ancient *Nicopolis ad Istrum*, founded by Trajan.

Nico'sia, a town of Sicily, province of Catania, 48 miles E.S.E. of Termini, has a cathedral, four large churches, and a college with a fine library. It carries on a lively trade in wine, oil, grain, and cattle, but has no manufactures, and is reckoned the most backward of all the Sicilian towns, 94 per

cent. of its inhabitants being unable to read. The dialect shows the place to have been a Lombardic colony, founded probably by Roger II. Pop. (1874) 14,789. N. is also another name of Lefkosia (q. v.) in Cyprus.

Nicotia'na. See TOBACCO.

Nicotine ($C_{10}H_{14}N_2$), a powerfully poisonous alkaloid found exclusively in the tobacco-plant (*Nicotiana tabacum*). It is obtained in solution combined with malic and citric acids by boiling the leaves in water. This liquid is then strained, evaporated to a syrupy consistency, and mixed with alcohol, when it forms two layers, from the upper of which the salts of N. are drawn off dissolved in alcohol. The N. is then set free by the action of potash and dissolved in ether, which is subsequently evaporated, leaving a colourless oily liquid which becomes brown when exposed to the air. This liquid is N., and is readily distinguished by its pungent odour. It boils at $250^{\circ}C.$, and is readily soluble in water, alcohol, and ether. See TOBACCO.

Niebuhr, Karstens, born on the 17th of March 1733, at Lüdingworth in Hannover, studied mathematics at Hamburg and Göttingen, and entering the Danish service as lieutenant in the engineers (1760), was attached to an expedition fitting out at the cost of Frederik V. for the exploration of Arabia (1761). All N.'s colleagues perished in this unfortunate journey—the philologist Von Haven at Mocha (May 25, 1763), Forskål the naturalist at Jerim (July 11), the painter Baurenfeind on the voyage to Bombay, and at the last-named place Cramer the physician (February 11, 1764). N., who alone had adopted the Eastern habit and mode of life, with singular intrepidity now proceeded on his homeward journey by way of Persia, Mesopotamia, Palestine, and Cyprus, reaching Copenhagen in the November of 1767. He published the results of his invaluable researches in *Beschreibung von Arabien* (Cop. 1772) and *Reisebeschreibung von Arabien und andern umliegenden Ländern* (2 vols. Cop. 1778-78; vol. iii. supervised by his daughter, 1837), and edited Forskaal's *Descriptiones Animalium* (1775), and *Flora Aegyptiaco-Arabica* (1776). N. was made captain (1768), notary at Meldorf in Slesvig-Holstein (1778), a member of the Institute of France (1802), and councillor of state (1808). He died April 26, 1815, having latterly become quite blind. See his son's *Leben Karstens N.* (Kiel, 1817).

—**Barthold Georg N.**, only son of the preceding, born at Copenhagen, August 27, 1776, was educated at Meldorf, and studied philology and jurisprudence at Kiel (1794-96). He was appointed supernumerary Secretary to the Royal Library of Copenhagen (1797), spent a year and a half in London and Edinburgh (1798-99), at the latter place meeting Walter Scott, and on his return to Denmark became assessor in the E. Indian department, and secretary to the African consulate (1800). In 1806 N. entered the service of Prussia as joint-director of the chief Berlin bank, and in 1809 was dispatched to Amsterdam to negotiate a loan. He exchanged his financial post for that of royal historiographer in 1810, the year of his election to the Prussian Academy, and of the masterly course of lectures on Roman history, published under the title *Römische Geschichte* (2 vols. Berl. 1811-12). The War of Liberation (1813-14) broke up the philological society consisting of N., Buttmann, Spalding, Schleiermacher, and other scholars. In 1814 he was again sent to Holland; 1815 he spent in writing a biography of his father, and in editing Fronto; and in 1816 he was appointed ambassador to the Papal court. At Rome N. continued to deepen and extend his studies, always, however, 'deploring with a sad heart' that he should have 'left the path of a teacher or professor to enter upon a life of trouble.' In 1822 he applied for his recall, and after visiting Albano and Naples, returned to Berlin (1823). Thence he withdrew to Bonn, where he founded the *Rheinische Museum* (1827), entirely recast his history (1827-28; Eng. trans. by Hare and Thirlwall, 2 vols. 1828-32), and continued to lecture in a non-official capacity until his death, January 2, 1831. N.'s *Römische Geschichte* marked, in the truest sense, an epoch in the writing of histories. From the mass of disjointed fable, hitherto accepted or thrown aside at the historian's caprice, he conscientiously strove, by the aid of philology, ethnology, and archaeology, to sift a residuum of truth; and the success of his system is shown by its forming, not only the basis of all succeeding histories of Rome, but a model to historians generally. That system necessarily contained many minor inaccuracies, and left gaps to be filled in by later writers;

N.'s style, too, was ponderous and ungraceful, and Macaulay, in the preface to *Lays of Ancient Rome*, speaks of him as 'a man who would have been the first writer of his time, if his talent for communicating truths had borne any proportion to his talent for investigating them.' N.'s posthumous writings include the third volume of his *Römische Geschichte*, bringing it down to 264 A.D. (Berl. 1832; Eng. trans. by Drs. Smith and Schmitz, 1851); *Vorlesungen über Röm. Gesch. an der Universität Bonn* (Jena, 1844; Eng. trans. 1848-52); *Gesch. des Zeitalters der Revolution* (2 vols. Hamb. 1845); *Sämmtliche historische und philologische Vorträge* (Berl. 1846). See *Lebensnachrichten über Barthold N.* (2 vols. Hamb. 1838); and Miss S. Winkworth, *The Life and Letters of Barthold N.* (3 vols. Lond. 1852).—**Markus Oersten Nikolaus von N.**, a son of the preceding, was born at Rome, April 1, 1817, and studied at Kiel, Bonn, Halle, and Berlin. After a lengthened residence in England, France, and Belgium, he became a journalist at Berlin, and travelled in Italy (1846-47). At first a warm advocate of reform, since 1848 he attached himself to the ultra-Conservative party, and rapidly rose to be councillor (1850), cabinet secretary (1851), and councillor of state (1854). Ennobled in 1857, he died at Oberweiler, worn out by overwork and the attacks of his opponents, August 1, 1860. Amongst other works he published a *Geschichte Assurs und Babels* (Berl. 1858).

Niel, Adolphe, a French marshal, was born at Muret (Haute Garonne), 4th October 1802, entered the *Corps du Genie* in 1825, became captain in 1835, and led a company at the storming of Constantine. He was head of Marshal Vaillant's staff in the Roman expedition of 1849, was made a general of division in 1853, accompanied the French expedition to the Baltic under Baraguay d'Hilliers, and directed the siege of Bomarsund, and afterwards that of Sebastopol. In 1857 he became a senator, commanded the 4th Corps d'Armée in the Franco-Austrian War of 1859, and fought with distinction at Solferino. In 1867 he was appointed Minister of War, and was actively engaged in reorganising the French Army when he died, 14th August 1869.

Niello Work consists in engraving a design on silver or other metal, filling the incisions with a black alloy, and then burnishing the whole surface to contrast effectively the bright metal with the dark design. The alloy is composed of silver, copper, lead, and sulphur, and is easily fused with the aid of borax. Owing to its black colour the Italians called it niello from the Low Lat. *nigellum*. This art is very ancient, and survived the dark ages only to be carried to greater perfection by the goldsmiths of Italy and Germany in the 15th c. It ceased to be practised in the 16th c., but not before it had given rise to the art of copper-plate engraving, which was a natural sequence to the improvements effected in taking casts or prints of N. W. in progress. N. W. has to some extent been revived of late years in France and Russia, and is applied to the decoration of jewel-boxes, sword and knife handles, &c.

Niemcewicz, Julian Ursin, a distinguished Polish author and statesman, born, 1757, at Skoki in Lithuania, entered the Polish army in 1777, which he left in 1788 with the rank of major, to work in the Diet for a new constitution. In 1794 he was adjutant to Kosciuszko, with whom he was taken prisoner, but liberated by the Emperor Paul, after which both went to America. In 1807 N. returned, and was made secretary of the Senate of the new grand-duchy of Warsaw, and in 1814 chairman of the Constitutional Committee, but lived chiefly on his estate, busied with study. After the failure of the Polish Revolution in 1830, he fled to England, which he afterwards left for Paris, where he founded a Polish library and historical society, and died 21st May 1841. His chief works are *Historical Songs of the Poles* (Warsaw, 1816, et seq.; Germ. trans. by Gaudy, Leips. 1833); *History of the Government of Sigismund III. of Poland* (3 vols. ib. 1819); *Collection of Memoirs for Ancient Polish History* (5 vols. ib. 1822); *Levi und Sara, Briefe Polnischen Juden* (Berl. 1825); the novel *John of Tencsyn* (3 vols. Warsaw, 1825; Germ. trans., Berl. 1828); and the posthumous *Notes sur ma Captivité à Pétersbourg* (Par. 1843). His poetical works were collected in 12 vols. (Leips. 1840), and his life was written by A. Czartoryski (Par. 1860).

Nie'men (Ger. *Memel*), a river of Prussia, 640 miles in length. It rises in Russia, becomes navigable at Grodno, 400

miles from its mouth, and at Winge, 8 miles below Tilsit, divides into the Russ and the Gilge, both of which fall into the Kurisches-Haff.

Niepce, Joseph Nicéphore, the first discoverer of photography, was born at Châlon-sur-Saône, March 7, 1765. On the outbreak of the Revolution he entered the army and served as a lieutenant in the Italian campaign in 1793. His weakness of sight, however, compelled him to return to France, where from 1795 to 1801 he acted as administrator of the district of Nice. He then settled in his native town and devoted his time to mechanics and latterly to chemistry. About 1813 the idea of taking pictures by sunlight appears to have suggested itself to him, and by 1824 the first practical difficulties had been overcome, and sun-pictures formed on glass or tin-plate. He communicated his discovery, concealing however his methods, in 1827 to the Royal Society of London, and two years later entered into a partnership with Daguerre, who after the death of N. published the process, simplified and improved no doubt, under his own name. N. died at Châlon-sur-Saône, July 5, 1833.—**Olaude Felix Abel N. de Saint Victor**, nephew of the preceding, was born at St. Cyr, near Châlon-sur-Saône, July 26, 1807. He entered the army, and in 1854 was nominated Commandant of the Louvre. He early turned his attention to the chemistry of colouring matters, did great service in improving the photographic methods of his uncle and Daguerre, and communicated to the *Comptes Rendus* numerous papers upon these and allied optical phenomena. He has written *Traité Pratique de Gravure Héliographique* (1856).

Nierstein, a village of Hessen-Darmstadt, Germany, 9 miles S.E. of Mainz, gives name to a delicate Rhenish wine produced in its neighbourhood. It has a pop. (1875) of 2761.

Nieuwer Amstel, a town of the Netherlands, province of N. Holland, 5 miles S.S.W. of Amsterdam, has some manufactures, and a pop. (1873) of 6171.

Nieuwveld Mountains, a range constituting a portion of the chain which forms the watershed of Cape Colony, and extending from W. to E. in the parallel of 32° S. lat. from 21° 45' to 24° E. long. On the inland side the N. M. form an elevated plateau with a very gradual slope, and are drained by the Zak, a tributary of the Orange River. Their average height above the sea is 5000 feet, and above the Karroo (q. v.) 2000 feet, but they rise in Bulbholder's Bank to a height of 7300 feet above the sea level. The range is singularly destitute of trees.

Nièvre, a central department of France, extends along the E. bank of the Loire and the Allier, and is watered by the Yonne, an affluent of the Seine, and by the N., a small tributary of the Loire. Area 2623 sq. miles; pop. (1872) 339,917. It is in great part hilly and woody, and yields, besides wheat for home consumption, some 6,000,000 gallons of wine, and a large supply of timber, iron, copper, lead, coal, and marble. Nevers is the capital; other towns are Cosne and Clamecy. N. is traversed by several important canals, and by the Paris and Lyons railway.

Niflheimr ('the mist-world,' Ger. *Nebelheim*), in Scandinavian mythology was one of the two worlds which existed before the earth was created. It lay in the extreme N., separated by Ginnungagap ('yawning gap') from its opposite, the bright and burning world Muspellheimr ('fire-world') in the S., and was the abode of Hel (q. v.).

Nigella, a genus of annuals belonging to the natural order *Ranunculaceæ*, chiefly natives of the countries bordering the Mediterranean, and of the western parts of Asia. There are about 20 species. The black, peppery, and aromatic seeds of *N. arvensis* or fennel flower—so called from its finely cut leaves—are commonly used in Eastern countries for seasoning purposes. In Egypt they are eaten by the ladies under the impression they effect improvement in the personal appearance. *N. Damascena*, a frequent border annual in gardens, bears the names of 'Love-in-a-Mist' and 'Devil-in-a-Bush,' from its flower in the one case, and its horned capsules in the other, being enveloped in a dense entanglement of the finely-divided involucre. Its properties are similar to those of the preceding species.

Niger (properly *N. egypticus*), a great river of W. Africa, which is also called Joliba above Timbuktú, and Quorra in its

middle course, all these names meaning simply 'river.' It rises in a recess of the Kong Mountains, behind Sierra Leone, flows first N.E., and then bends round to S.E., entering the Gulf of Guinea, after a course of some 2500 miles, its 22 mouths forming a delta larger than that of the Nile. Before reaching its most northerly point it splits into two branches, which enclose the island of Jimballa, 220 miles long. Below Kabara, the port of Timbuktú, the valley as far as Say is marshy and broken by numberless creeks; from Say to Bussa the stream is impeded by rocks and shoals. Receiving its two great affluents, the Sokoto and Benue, from the watershed which separates its valley from the basin of Lake Tchad, it rounds the eastern shoulder of the Kong Mountains, where the scenery is singularly romantic. The delta, intersected by the main branches, Bonny, Mari, and Nun, is covered with a rank forest of mangroves. The best known states in the upper N. valley are Bambarra, a country of the Mandingos, Masina, including Timbuktú, Songhay, a marshy country, and Gando, to which belong the towns Say and Bussa. Among the explorers of the N. are Mungo Park, Caillié, Lander, Allen, and Dr. Barth. Great part of the river is still unknown, and the *Société Géographique* of Paris announced its intention in October 1877 of sending an expedition to complete the work of exploration. See F. de Lanoye, *Le N. et les Explorations de l'Afrique Centrale* (Par. 1860).

Niger Liber, the name given to the black book, or register, in the Exchequer.

Nighthawk, otherwise named the Virginian Goat-sucker and the Mosquito Hawk, is an *Insectorial* or Perching bird, belonging to the suborder *Fissirostres* (q. v.), and to the family of *Caprimulgidae* or Goat-suckers. The N. is the *Chordeiles Virginianus* of ornithologists. It inhabits the northern parts of the New World. Most of the goat-suckers are nocturnal in habits, but the N., although active at night, is known to fly about also by day in pursuit of its prey. The mouth, as in all *Fissirostres*, is large, and the 'gape' is fringed with bristles, which appear to be serviceable in the capture of insects. The N. attains a length of 9 inches. It is generally of a dark brown colour. A greenish gloss adds lustre to the plumage of the upper parts, and a number of small yellow spots diversify the plumage of the head and neck. A white patch is conspicuous on the throat. The tail is forked, and the wings exceed the tail in length. The bill is small.

Night-Heron, a group of *Ardeideæ* or Herons (q. v.), so named from pursuing its prey during the night. The Common N.-H. is the *Nycticorax Europæus*, and another species, the Nankeen N.-H., named *N. Caledonicus* by naturalists, occurs in Australia. The Common N.-H. is found in both hemispheres, and is occasionally seen in Britain. Its average length is 2 feet, and its colour an ashen-grey, varied with black on the head and neck, and white below. The bill and legs are shorter than in the common heron. Three slender feathers form a crest which droops from the back of the head. The Nankeen N.-H. is a beautiful species, widely distributed over the Australian continent. It is of a rich brown colour; the head is black, the crest, eyebrows, and the whole of the under surface being white. The bill is black, and the legs and feet yellow.

Nightingale (Old Eng. *nihtgale*, 'the night-singer'; cf. Ger. *nachtigall*), one of the most beautiful of songsters and least noticeable of birds. Its appearance is dull; but its lack of brilliant plumage is amply compensated for by the clearness, sweetness, and range of its notes. Both in ancient and modern times it has been celebrated in verse and prose. The N. belongs to the order of *Insectoria* (q. v.) or that of the Perching birds. It is included in the *Dentirostral* section of this order, and appears as a member of the Warbler family (*Sylviidae*), although some authorities have constructed a special family (*Luscinidae*) for its genus and allied genera. The N. is scientifically designated *Philomela luscinia*

Virginian Nightingale.

or *Luscinia philomela*. The characters of the N. genus are the short bill, destitute of bristles; the rounded opening of the nostrils, and the length of the third quill. The tarsi are covered in front by one long scale. The N. is a rare visitant in Scotland and Ireland, and in England appears to be local in its distribution, and to affect some localities during a period of years, disappearing thence for many successive seasons. Its colour is a dingy brown above; the under parts are a dull grey, the throat showing a lighter tint than the belly. The average length is 6 or 7 inches. The eggs, numbering four or five, are olive-brown. The nest is constructed near the ground. It is of slight make, and is usually securely concealed by foliage. The food of the bird consists of worms and insects, but it appears to devour berries and other fruits in autumn. When tamed, mealworms and a modicum of raw beef and hard-boiled eggs constitute its favourite dietary.

The N. is famed for its twilight and nocturnal song, but it sings through the day as well. The notes are clear, prolonged, and thrilling; at times apparently plaintive, and again,

"Tis the merry nightingale,
That crowds and hurries and precipitates,
With fast thick warble his delicious notes."—(Coleridge.)

The young are hatched in June, at which time the song appears to become harsher. The N. is migratory in habits. It arrives in Britain in April, the male appearing before the female, and flies southwards (most probably to N. Africa) in September. The male is taken before pairing, as when captured after pairing, it usually pines and dies.

Nightingale, Florence, was born of wealthy English parents at Florence, in May 1823. She early showed an unusual interest in hospitals, and employed the opportunities afforded by frequent visits to the Continent with her parents to inquire into the state and management of these institutions. In 1851 she went to Kaiserwerth, on the Rhine, for practical instruction in the work to which she was to consecrate her life. After remaining there three months, she took the management of the Harley Street Hospital in London, and sacrificed a large part of her fortune in reorganising that establishment. During the Crimean War, when terrible tidings reached England as to the state of the military hospitals, Miss N., though herself suffering, hastened to the relief of the wounded soldiers. On the 27th October 1854 she sailed for Scutari, in the service of the War Department, with a band of trained nurses under her. She afterwards proceeded to Balaclava, where by her energy and skill she saved thousands from death. Though attacked by Crimean fever, she refused to quit the seat of war, and only returned to England in August 1856, when the war was ended and the hospitals almost closed. In recognition of her services the public raised £50,000 as a testimonial—the so-called 'N. Fund'—which, at her request, was chiefly devoted to the extension of St. Thomas' Hospital. Her principal writings are *Notes on Hospitals* (1859); *Notes on Nursing* (1860); *On the Sanitary State of the Army in India* (1863); *Notes on Lying-in Institutions* (1871).

Night-jar. See GOAT-SUCKER.

Night-mare (*night*, and Old Eng. *mara*, 'a spectre'), or **In'oubus**, is a sensation experienced in sleep, resembling the pressure of a weight on the chest as if from some hideous monster, from which there is invariably an impossibility of escape. N. is simply a form of Dreaming (q. v.), the dreams being of a disagreeable and frightful nature, involving a sense of immediate and inextricable danger, and is usually attributed to plethora, posture during sleep, indigestion, or heavy suppers. Among savage and semi-civilised races, and among the insane, N. is usually ascribed to the influence of supernatural agencies, or to experiences actually undergone during slumber. N. is most frequently induced by errors in diet, or weakness of the digestive functions.

Nightshade, a name given to the British representatives of the genus *Solanum*. One species has already been described under Bittersweet. The other is an annual that occurs in waste places in England, and occasionally in Scotland. As a weed, it is also now found in most temperate and tropical regions of the world. It bears ovate wavy leaves, drooping flowers with a white corolla, succeeded, in the ordinary form, by

black berries—hence its name of *S. nigrum*. Like most of its congeners it possesses narcotic properties—though only to a slight degree; and the leaves in Bourbon and Mauritius are eaten as spinach. See BELLADONNA for Deadly N. and CIRCEA for Enchanter's N.

Nigra, Constanti'no, an Italian diplomatist, born 12th June 1827, at Ivrea in N. Italy, where he studied law and philosophy (1845–48), after which he became secretary, first to Azeglio and then (1852) to Cavour, whom he accompanied to Paris and London in November 1855, and at the Peace of Paris in 1856. N. was one of the Sardinian plenipotentiaries at the Peace of Zürich in 1859, and in 1860 was appointed Sardinian ambassador at Paris. In January 1861 he became the chief minister of Prince Carignan, who at that time went to Naples as governor-general; but in the same year N. was appointed Italian ambassador at Paris. Here he played a prominent part in the Franco-Italian Convention of September 15, 1864, and remained till June 1876, when he was sent to St. Petersburg as ambassador for Italy.

Nijmegen (Ger. *Nimwegen*, Fr. *Nimeguen*), a fortified town of the Netherlands, in the province of Gelderland, on the left bank of the Waal, 9½ miles S. of Arnhem. The church of St. Stephen (1272) is a fine specimen of the Gothic style. Of the old castle of the Karolings, the Walkenhof, in which the Burggrafs of N. afterwards resided, only some poor ruins remain. The oldest building in N. is the Baptistery, consecrated 799. N. has considerable trade in corn, and manufactures tin, iron, and wooden wares, and beer. Pop. (1874) 22,929. In the Middle Ages N. was an important member of the Hanseatic League. On the neighbouring Mooker Heath the Counts Ludwig and Heinrich of Nassau were (1574) defeated by the Spaniards, and in the town-house of N. were concluded the peace of 1698 between the Netherlands, France, and Spain, and of 1679 between France, Sweden, and the German Empire.

Nijni-Novgorod, a government in the E. of Russia, is bounded N. by Kostroma, S. by Pensa, E. by Kasan and Simbirsk, and W. by Vladimir. Area, 19,390 sq. miles; pop. (1870) 1,262,913. Watered by the Volga, Sura, Vetluga, and Oka, it is to the extent of one-half under forests, while some two-fifths are arable land, and the rest is under pasture. The inhabitants, especially along the banks of the Volga and Oka in the N., are largely engaged in industrial pursuits, and the products, chiefly iron, soap, tallow, candles, leather, gloves (300,000 pairs yearly at Bogorodsk), and the finest Russian ropes, amount annually to £428,000. Some 70,000 of the inhabitants are Mordwins, 37,000 Karafaks, and 7000 Cheremissians.

Nijni-Novgorod ('lower New Town'), capital of the Russian government of the same name, situated at the confluence of the Volga and Oka, 720 miles E. of Moscow by rail. One of the oldest towns of Russia (founded in 1221), it is in part girt by old walls, and has a kremlin (1523), a royal palace, two cathedrals, twenty-five other churches, many synagogues, mosques, theatres, hotels, &c. It is the seat of the greatest fair in the world, the Peter-Paul's Fair (Russ. *Jarmarka*), which begins about the 27th July, and lasts for a month. Here the merchants of Europe meet those of Turkestan, Armenia, Persia, India, and China, and the representatives of the various nations occupy separate streets or bazaars. In 1874 the imports were valued at £25,743,000, and the sales amounted to £23,544,000. Among the chief articles were cottons (£5,399,000), woollens (£3,384,000), linens, hemp, and paper (£798,000), silk, and silk wares (£979,000), furs (£1,113,000), gold and silver wares (£2,265,000), iron, steel, and copper (£852,000), glass, porcelain, &c. (£336,000), grain (£336,000), wines and other liquors (£701,000), tea (50,000 chests), and China wares (£3,633,000), Persian wares (£1,331,000), and products of Khiva and Bokhara (£384,000). In addition to 2530 permanent stores, some 3400 wooden booths are erected yearly, to accommodate the influx of visitors, who are estimated at not less than 200,000. The most costly articles sold are furs, Cashmere shawls, and pearls. No tax whatever is imposed on the trade, by far the greatest quantity of which comes by the Volga and Oka. The rivers are here crossed by a pontoon bridge, and in the commercial part of the town a great exchange has been erected at a cost of £1,571,000. Pop. (1870) 40,472. As early as the 9th c. a great fair was held at Bolgary or Balcirinoft, the chief town of the Bulgarian king-

dom on the Volga and Kama. Subsequently this fair was transferred to Kasan, then to Makarief, and finally to N., on the partial destruction of Makarief by fire in 1817. Of late years there has been a marked falling off in the attendance of Orientals from Central and Eastern Asia, who are assigning instead of accompanying their wares. See *A Trip up the Volga to the Fair of N.*, by A. M. Butler-Johnstone, M.P. (Lond. 1875).

Nijni-Tagilak, a town in the government of Perm, Russia, on the river Tagil, in a valley of the Urals, 150 miles E. of the town of Perm. It is the centre of one of the richest mining districts in the world, and near it is the great magnetic mountain of Blagodot, 1422 feet high. The works employ 17,000 men, and in 1864 produced 32,616,468 lbs. of iron, 1,652,128 of copper, 345,348 of steel, 1086 of gold, and 3600 of platina. Akinfi Demidoff set up the first foundry here in 1725. Pop. 30,000.

Nikolaef, a town of Kherson, Russia, at the confluence of the Bug and Ingul, and 25 miles from the entrance of the former into the Black Sea, 75 miles E.N.E. of Odessa. It is the chief station of the Russian fleet in the Black Sea, is strongly fortified, and has 18 churches, 2 synagogues, a handsome admiralty house, several barracks, an arsenal, an observatory, a fine naval hospital (erected in 1874), 3 libraries, &c. In 1875 the imports, chiefly coals, iron rails, machinery, armour plates, and cement, amounted to £234,088; the exports, wheat, rye, barley, oats, linseed, rapeseed, and timber, to £1,215,934. Of the 135 vessels that entered the port 83 were British of 60,511 tons. A line of Dutch steamers between N. and the west of Europe, in conjunction with the N.-Kharkoff Railway, began running 1875. The river is usually frozen over from December till the end of April. Pop. (1870) 67,972.

Nikolaevsk, a town of Siberia, on the left bank of the Amur, is one of the chief towns in the Amu territory, and has a considerable export trade in furs, skins, walrus teeth, &c. The river is frozen over for six months, and the mean annual temperature is 39° 42' F. Pop. 5000.

Nikolsburg (*Niklöv*), a town in the S. of Moravia, in a rich wine-growing district, 25 miles S. of Brünn, with which it is connected by rail. It has a beautiful church and a castle of the former princes of Dietrichstein, with fine gardens and art collections. There is some industry in cottons and silks, and a large trade in red wines. Pop. (1869) 7173, of whom 4000 are Jews.

Niko'pol, a town in the government of Ekaterinoslav, Russia, on the right bank of the Dnieper, 200 miles from its mouth, and 150 above Kherson. In 1873 its exports, chiefly grain, linseed, and timber, amounted to £754,373, and its imports to £35,487. Pop. 8758.

Nile (Gr. *Nilos*; Egyptian *Hapi Mu*, 'genius of the waters'; Heb. *Sihor*, 'the black'), one of the most celebrated rivers in the world, the longest in Africa, and an object equally of wonder and veneration to the ancients and of eager curiosity in modern times. Interesting no less on account of the singular and important part it plays in the economy of Egypt than of the mystery which, despite the keenest exploring enterprise, has so long veiled the problem of its source, it is a link between the seat of the most ancient civilisation and perhaps the most unknown and least civilised part of the habitable globe. Recent researches render it almost certain that the White N. has its origin in Lake Victoria Nyanza and the Shibiya, a considerable river flowing into its S.E. corner. It leaves the lake at the Ripon Falls, which are 12 feet high, and in lat. 0° 20' N. and long. 33° 30' E., in a stream 150 yards broad, and flows in a direction N.W., passing through the head of the Lake Albert Nyanza. This part of the river is usually called the Victorian N., and the country, Uganda, Unyoro, and Madi, is singularly fertile, and in parts is overgrown with rank forest and grass. From Albert Nyanza its course is first N.N.E. and then due N. as far as Gondokoro, or Ismailia, as the station was named by Sir Samuel Baker in 1871. In this stretch the river passes through a rugged mountain country, partly covered with low open forests of scrubby trees, and receives from the right the waters of the Unyama, Ashua, and Attabi. Above Affudo, at the mouth of the Unyama, it is navigable to Lake Albert Nyanza, so that Affudo or 'Ibrahimeya' is likely to become the centre of commerce in the country. At Ismailia the N. during the rainy season does not rise gradually, but by a series of sudden flushes,

and to a height of 4 feet in about twelve hours. The rise is caused by heavy rains in the S. sending down an immense volume of water from the high mountains which line the W. bank of the N., and by the Ashua, Unyama, and other streams. After the fall of the river, the marshes give off a horrible effluvia, which occasions much fever. Leaving the Bari country at Ismailia, the N. has a course to the Bahr-el-Gazal generally N.N.W. for nearly 400 miles, traversing the native territories of Schir, Bohr, Aliab, Kika, and Nuehr. Throughout this distance the bed is for the most part level and marshy, and the river frequently branches. The Bahr-el-Ghazal, the only great tributary of the N. on the left, was called by Speke in 1863 'an unimportant branch,' but has been shown by Schweinfurth to have a drainage area in the country of the Dinkas, Bongos, and Niam-Niams, of not less than 150,000 sq. miles. At this point the N. takes a sharp bend to the E., and here for a considerable distance its channel is choked with recent deposits of vegetable matter, covered with tall grass and clumps of papyrus. Traders avoid this part of the river, travelling by the Bahr Zaraffe or Giraffe River, an arm of the N., which leaves it in latitude 5° 20' N. and joins it again in latitude 9° N., about 36 miles above the confluence of the Sobat. The Bahr Zaraffe has itself been obstructed since 1871, but in 1872-74 Ismail Pasha, governor of Khartum, with a large force was successful in clearing away great part of the N. stoppage. Some 110 miles E. of its junction with the Bahr-el-Ghazal, the N. is joined by the Sobat from the E., a grand navigable tributary, here 250 yards wide. Turning abruptly N. once more, the N., a stream varying in breadth from one to two miles, with the country of the Shilluks on the W., and further on separating Kordofan from Sennaar, is augmented at Khartum (q. v.) by the waters of the Blue N., formed by the junction of the Abai and Blue River. The Blue N., over 1000 miles long, descends from the region of Lake Dembea in Abyssinia. Below Khartum the N. is better known. At El Damer, 170 miles below, it receives its last great affluent, the Athara or Bahr-el-Asward, after which it makes a great bend in the Nubian deserts, descending the terraces of Nubia by a series of cataracts, the last of which is at Assouan (q. v.) on the Egyptian boundary, in latitude 24° 10' N. Hence it flows in a northward curve with a steady stream at the mean rate of 3 miles an hour, and an average fall of 2 inches to a mile. Although receiving no affluent from the Athara to its mouth, a distance of 1500 miles, and though crossing an extensive stretch of sandy desert under a burning sun, it brings an enormous volume of water to fertilise the rainless Egyptian plains. The Athara ('black river') receives its name on account of the mud which it brings down, and which, when deposited by the annual overflow of the N., is the true fertiliser in Egypt. Along its lower course as far as Cairo the N. is confined in a valley lined on both sides by high naked rocks. Its delta is 150 miles broad at the sea, and is intersected by a maze of streams of which the principal are the Rosetta and Damiatta branches. The N. drains nearly a tenth of the whole area of Africa, and has a total length of 3500 miles. An account of its annual overflow, the most wonderful of all hydrographic phenomena, is given in the article on Egypt. The river is abundantly stocked with fish, and among the birds which swarm along its banks are vultures, cormorants, pelicans, geese, quails, and white ibis. As a drink, its water when filtered is among waters what champagne is among wines. The basin of the N., long notorious as a centre of the slave-trade, has been claimed by the Egyptian government as far S. as Uganda, and to within 35 miles of Victoria Nyanza, since the military expedition under Sir Samuel Baker, sent by the Khedive to suppress the iniquitous traffic in 1873. Among the travellers who in recent years have contributed most materially to our knowledge of the Upper N. are the brothers Poncet (1857), Petherick (1858 and 1862), Henglin (1863-64), Captain Burton (1857-59), Captain Speke (1857 and 1861), Captain Grant (1861), H. M. Stanley (1871-77), and above all Sir Samuel Baker (1861 and 1870-73), Dr. G. Schweinfurth (1868-71), and Gordon (1874-76). Of the host of travellers who have made the attempt, only Baker, Schweinfurth, and Gordon have succeeded in penetrating from the N. to the equatorial N. regions. Livingstone, whose name is more widely identified than that of any other traveller with the problem of the Caput Nili, and who was virtually a martyr to its elucidation, carried his researches into a field lying beyond the actual basin of the river. And although his discoveries in the region of lakes

Tanganyika and Bangweolo, and the course of the Lualaba, are of the greatest value as contributions to our knowledge of Central African geography, his theory identifying the Lualaba with the N., in which indeed his own belief was latterly shaken, has been finally disproved by Stanley's explorations of the former river, the splendid results of which were made known to the world in November 1877. After leaving the Bagenya country, to which Livingstone had traced it, the Lualaba flows in a north-easterly direction, as if to join the N., but subsequently takes a westerly bend, and in its lower course becomes the river known as the Congo. To this river Stanley, in graceful compliment to the great missionary traveller, has given the name of 'Livingstone.' For the literature of N. discovery see, besides the works of the travellers whose names are above mentioned, the *Journal of the Royal Geographical Society*, the *Geographical Magazine*, and Dr. A. Petermann's *Mittheilungen* for recent years.

Nile, Battle of. See ABOUKIR and NELSON.

Nilometer is an instrument for measuring the rise of water in the Nile (q. v.) during its annual inundation. That erected on the island of Er-Rodah opposite Cairo is simply a graduated pillar set in a well which communicates with the river. It dates from the year 847 A.D. Of older date is the N. at Elephantine, which consists of a stair descending between two walls to the Nile. On the one wall lines are inscribed marking the rise of the water in former years.

Nils'son, Christine, a leading *prima donna*, the daughter of a peasant, was born at Hussaby, near Wexio, Sweden, August 3, 1843. Her playing and singing at a country fair in June 1857 attracted the attention of a gentleman of means, F. G. Thornerhjelm, who placed her at a school at Halmstad, and afterwards with Franz Berwald, as her master, at Stockholm. On completing her education under Nasset and Wurtel at Paris, she made her first appearance in October 1864 at the *Théâtre Lyrique* in that city, where she obtained a three years' engagement. In the season of 1867 she made a brilliant *début* in London, where, as well as in Paris, St. Petersburg, and Vienna, she has taken the highest rank as a public favourite. She visited the United States, 1870-72. On the 20th of August 1872 she married M. Auguste Rouzaud, the son of a well-known French merchant. Her voice is a soprano of extraordinary range and richness, while her dramatic talent is a splendid ally to her wonderful vocalisation. Among her grandest parts are Violetta in *Mariota*, and Valentine in the *Huguenots*. But she excels in the more poetical conceptions of the opera. In *Faust* she is the most perfect of Marguerites, in *Lohengrin* the most ideal of Elsas.

Nimar, the most westerly district of the Central Provinces, British India, lying across the valleys of the Nerbudda and the Japtee and the intervening hills. Area, 3340 sq. miles; pop. (1872) 211,176. This tract was the home of the Pindari marauders at the commencement of the present century. It is now traversed throughout by the railway, and has become the centre of the trade in Malwa opium. In 1874-75 its total imports were valued at £1,900,000, almost solely opium; its exports at £350,000, chiefly piece-goods and sugar. The chief towns are Khundwa (q. v.) and Bhanpur, at which latter there is a manufacture of gold-embroidered fabrics. N. is a favourite shooting ground for sportsmen from Bombay. Tigers and bisons are common.

Nim'bus (Lat. 'a bright cloud'), in painting and sculpture, a disc round the heads of divinities, saints, and sovereigns. When it encloses a cross, it belongs to Christ alone; without the cross, it indicates a canonised saint; when with radiating lines, it denotes one of the beati, persons exalted by the Church as worthy of imitation, but not canonised. The aureole is generally almond-shaped, and encloses the whole person. This is only associated with Jesus, or Mary with the Infant in her arms. The N. of Jesus or Mary is always of gold; those of saints or others may vary in colour. See Mrs. Jamieson's *Sacred and Legendary Art* (2 vols. 1848; new ed. 1874).

Nimeg'uen. See NIJMEGEN.

Nîmes, or **Nîmes** (Celt. *nemet*, 'a sacred grove'), a town of France, capital of the department of Gard, stands in the valley of the Vistre, 30½ miles N.E. of Montpellier by rail. Consisting of an old town connected by boulevards with eight suburbs, N.

contains a cathedral, eleven Catholic and eight Protestant churches; the Maison Carrée, a Roman temple, converted since 1823 into a museum; the citadel, built by Vauban, now a prison for 1400 convicts; a Palais-de-Justice, Hôtel-Dieu, and the magnificent marble fountain of the Place de l'Esplanade, erected by Pradier (1848) at a cost of 250,000 francs. In the factories of N. are more than 10,000 looms and stocking-frames. Silk-weaving has declined since 1750, but the manufacture of shawls, carpets, handkerchiefs, &c., employs 5450 artisans; of leather and shoes, 3200; and of iron, 300. The trade in brandy has an annual value of 7,000,000 francs, in cocoons and silk of 18,000,000 francs; and medicinal herbs are largely exported to Holland and Germany. Pop. (1872) 55,488, of whom more than half are Protestants. The *Nemausus* of the Romans, N. has the remains of an amphitheatre capable of holding 17,000 spectators; of a temple of Diana, baths, and triumphal arches. It came under the Visigoths in the 5th c., was sacked by the Norsemen (859), declared for the Reformation (1559), and suffered greatly on the Revocation of the Edict of Nantes (1685), and again in 1830.

Nim'rod, whose history is given in Genesis x. 8-12, was a son of Cush, i.e., he was an Ethiopian; his prowess as a hunter was so great that it became proverbial; he became king of Shinar or Babylonia, the four chief cities of his kingdom being Babel, Erech, Accad, and Calneh; and he then extended his empire northwards into Assyria (reading Gen. x. 11, 'out of that land he went forth to Assyria,' &c.), and founded a second group of capitals, Nineveh, Rehoboth, Calah, and Resen. The only other mention of N. in the Bible is in Micah v. 6, where the prophet uses 'land of N.' either for Assyria or Babylonia, and in 1 Chron. i. 10. But various other traditions regarding him have been preserved. Josephus says he was the prime mover in the building of the tower of Babel. Later writers make him a fire-worshipper, the inventor of idol-worship, and a contemporary of Abraham, whom he cast into a fiery furnace because he would not worship his idols. N. is the most prominent name in the traditions of the Arabs. Everything good or evil is attributed to him, and all the most important Chaldean ruins are called by his name. He has been identified with a great variety of historical personages by different writers: with the first king of Babylonia after the Flood (the Enochus of Berosus); with Bel, the great Babylonian god, and is said to have extended his dominions to the mountains of Armenia; with Ninus, the mythical founder of Nineveh; and even with the first king of Babylonia before the Flood (the Alorus of Berosus). Such was the amount of knowledge possessed regarding N. till 1872, when the late G. Smith, of the British Museum, discovered among the terra cotta fragments of the Royal Library at Nineveh a series of twelve tablets, containing Babylonian legends regarding the Deluge, the central figure in which legends is a hero who, according to Mr. Smith, corresponds exactly with the N. of the Bible. He was a giant hunter, who contended with and destroyed the lion, tiger, leopard, and wild bull. He first became king of Babylonia, and then extended his dominion to the Armenian Mountains, his court and palace being at Erech. Mr. Smith thinks it highly probable that these Babylonian legends, which were preserved in the royal libraries of the later kingdom of Assyria, were written down to about B.C. 2000, and therefore that the time of N. ought to be fixed at least not later than B.C. 2250. See Smith's *Chaldean Account of Genesis* (Lond. 1876).

Nin'evēh (probably a compound with the name of the Babylonian war-god Ninip), one of the most ancient cities of which there is any historical record, was the capital of the ancient kingdom of Assyria (q. v.). The first mention of N. in the Scriptures is in Genesis x. 8-12, in connection with Nimrod (q. v.), who extended the Babylonian kingdom over Assyria. The attention of the prophets Nahum (q. v.) and Jonah (q. v.) is entirely directed to it. It is mentioned that Sennacherib (q. v.) was slain there (2 Kings xix. 36, Isaiah xxxvii. 37), and the last mention of it as an existing city is in the Book of Zephaniah (ii. 13), about 630 B.C. It seems to have been burned about the end of the 7th c. B.C. The traditions of the great size and magnificence of N. preserved by Greek, Roman, and Arabic writers (cf. Jonah iii. 1-4), according to which the wall was about 60 miles long, 100 feet high, and broad enough to hold three chariots abreast, and defended by 1500 towers 200 feet high, are fully borne out by the discoveries which have recently been made in its ruins, which have been identified as the mounds

of Konyanjik on the E. bank of the Tigris opposite Mosul. See Layard's *N. and its Remains* (Lond. 1851) and *N. and Babylon* (1867), and George Smith's *Assyrian Discoveries; an Account of Explorations and Discoveries on the Site of N. during 1873 and 1874* (Lond. 1875).

Ningpo, a city of China, province of Chi-Kiang, on the confluence of two small rivers, 12 miles from the sea, and 100 S. of Shanghai. It lies in a fertile and populous plain, and is surrounded by walls 15 feet high and nearly 6 miles in circuit, and is intersected by numerous canals. There are many large and splendid temples, and a hexagonal tower of eleven stories, 160 feet high, mounted by a spiral flight of steps. The manufacture of silks, cottons, woollens, and salt is considerable, and the immediate vicinity yields a large quantity of green tea, rice, and the produce of the mulberry and tallow trees. In 1874 in the direct trade with foreign countries (including Hong Kong), the exports amounted to £2052, and imports to £534,576, while in the trade with the Treaty Ports the value of imports was £1,664,268, and of exports £2,151,825. As much as £2,541,077 of the latter trade (imports and exports) was carried on in native vessels. The direct imports from Great Britain amounted to £627,322, and the exports to Great Britain to £63,411. In 1873 there entered the port 253 foreign vessels of 174,977 tons (41 British of 17,571 tons), and cleared 253 of 175,444 tons (43 British of 17,813 tons). Pop. 500,000. N. was one of the five Treaty Ports opened 26th August 1842, and has both Protestant and Roman Catholic mission stations.

Ninian, St. (the *St. Ringan* of Lowland Scotch, and *Trinyon* or *Triman* of the North Country dialect) was born of royal parentage on the shores of the Solway Firth about the middle of the 4th c. Of studious and ascetic habits, he was fired by the Holy Spirit to make a pilgrimage to Rome, which he reached by way of the Gallican Alps, and where he was consecrated bishop by the Supreme Pontiff. On his homeward journey N. paid a visit to St. Martin at Tours, and after his arrival in Scotland founded the 'Candida Casa,' or church of Whithorn in Wigtonshire, dedicating it to St. Martin, who had just died (397). Later, N. laboured successfully for the evangelisation of the Southern Picts, and in 432 (according to the Bollandists) died, 'perfect in life and full of years,' and was buried in his cathedral church at Whithorn. His festival falls on the 16th September. Though the facts of his life, as well as independent testimonies, show that Christianity existed in Scotland prior to St. N., yet his apostolate is the first distinct fact in the history of the Scottish Church. And even of N. himself we can gather little that is definite from the Latin life by St. Ailred (born 1109, died 1166), which, while good in style, is almost worthless as an historical record. See Bishop Forbes' *Life of St. N.* in vol. v. of *The Historians of Scotland* (Edin. 1874).

Ninon de Lenclos. See LENCLOS.

Ninth, in Music, a dissonant interval one octave higher than the second, from which it differs in harmonic and contrapuntal treatment.

Niobe, daughter of Tantalus by the Pleiad Taygete or the Hyad Dione, was the wife of Amphiion, King of Thebes, to whom she bore six sons and six daughters. Proud of the number of her children, she exulted over Leto, who had only two—Apollo and Diana. These, indignant at such presumption, slew all the children of N. Nine days they lay unburied, but on the tenth they were interred by the gods. N., who had gone to Mount Sipylus, mourning the loss of her offspring, was changed into stone, and even in that form continued to feel her sad bereavement, and to give tearful expression to her woe. The story of N. and her children was a favourite subject with ancient artists. Some of the figures in the celebrated group found at Rome in 1583 and now preserved in Florence, exhibit the highest phases of ancient art.

Niobium or **Oolum'bium** (symbol Nb, atomic weight 94), a rare metal obtained from American columbite, and first discovered in 1801 by Hatchet, though for long, upon the authority of Wollaston, it was regarded as identical with *Tantalum* (q. v.), a metal with which it is ordinarily associated. The oxide (Nb₂O₅) is an acid, and forms niobates with strong bases. The chloride (NbCl₅) and oxychloride (NbOCl₃) are converted by water into the oxide.

Niort, a town of France, capital of the department of Deux-Sèvres, on the Sèvre-Niortaise, 49 miles S.W. of Poitiers by rail. It contains the churches of Notre-Dame and St. André (restored 1858-61), an Hôtel-de-Ville (formerly the palace of Eleanor, Henry II.'s queen), the remains of the castle in which Madame de Maintenon was born, a prefecture, theatre, public library of 30,000 volumes, museum, &c. Glove-making employs 1000 artificers, and other industries are market-gardening, tanning, dyeing, and manufactures of shoes, blouses, hosiery, cotton and woollen goods, oil, glue, &c. Pop. (1872) 17,470. Annexed to England from 1154 to 1224, N. was captured by the Black Prince (1356), but retaken by Duguesclin (1373).

Ni'pa, a genus confined to one species, *N. fruticans*, a palm-like plant, common in the seaside marsh lands of the E. Indies. The creeping stem bears tufts of leaves which often grow more than 20 feet in length, and are much used for thatching. The fruit consists of one-seeded drupes aggregated into large heads; their kernel is edible. From the spadix a toddy is obtained, convertible into a syrup, sugar, and an intoxicating spirit. Nipadites are the fossil representatives.

Nipon', or **Dai Nipon'** (i.e., 'land of the rising sun'), the native name of Japan (q. v.).

Nipple, the name given to the prominence on which the excretory ducts of the milk-glands of *Mammalia* open. N. may be altogether wanting in some Mammals (e.g., *Ornithorhynchus* (q. v.), and *Echidna*), while in the nearly allied *Marsupialia* (q. v.), represented by the kangaroos and their allies, the nipples are exceedingly long, and are adapted to attach the immature young securely to the parental body in the act of nutrition. The N. is never single, although an odd number may be found (as in some opossums). In the kangaroos four nipples exist. Eight N. arranged in a circle are developed in the Marsupial genus *Phascogale*. Each N. may be perforated by one canal or duct only—as in pigs, Ruminants, and whales. In horses and apes each teat is traversed by two canals; Rodents and Carnivorous animals have five or six ducts opening in each N.; while in elephants, Marsupialia, and Primates (*Quadrumania* and man), numerous milk-ducts open in each teat. For Diseases of the N. see MAMMARY GLAND, DISEASES OF.

Nirvāna (= 'blown out, extinguished,' derived from a Sanskrit root. In Pali, the classical language of Buddhism, it becomes *niibāna*), the ideal state of consummation in which the purified soul of the good finds its destined deliverance, both in the Hindu and Buddhist systems of religious philosophy. In accordance with the pure theism of the early Hindu writings, N. consists in the absorption of the soul into Brahma, the self-existent cause of the universe, from which it originally emanated, and in which it finds an eternity of bliss. On the other hand, the orthodox doctrine of Gautama Buddha, as preserved most purely in Ceylon, necessarily leads to the logical conclusion that N. is absolute annihilation, the cessation of the long train of misery called life. According to Rhys Davids, however, N. is properly 'the extinction of that sinful condition of mind and heart, which would otherwise be the cause of renewed individual existence.' For a summary of the views contained in Buddhist literature, and of those held by modern European critics, see Professor Childers' *Pali Dictionary, sub voc. Nibbanam* (vol. i. Lond. 1875), and Rhys Davids in the *Contemporary Review* for January 1877.

Niscomi, a town of Sicily, province of Caltanissetta, finely situated in a fertile district, 11 miles from the Tyrrhenian Sea, has corn and oil mills, and some remains of ancient dwellings. Pop. (1874), 10,750.

Nisibis (the *Nasibina* of the cuneiform inscriptions, Arab. *Nisibin*), an ancient town of N.E. Mesopotamia, on the river Mygdonius (Aram. *Mygdan*), and in the province of Mygdonia, from which it was named by Seleucus Nicator 'Antiochia Mygdonia.' Founded by the Armenians before the time of Alexander the Great, N. was during the last 150 years B.C. the residence of the Armenian kings, from whom it was taken 68 B.C. and held for a time by Lucullus. Deserted by the Armenians, it was seized in the 1st c. A.D. by the Parthians, after whose subjugation by Trajan it came under the Romans. It was the centre of the great Jewish insurrection about 130. Being equally important as the chief seat of Syrian learning, religion, and

trade, N. was long and keenly contested by the Romans and Parthians. It was taken by the Persians in 363, and in the 7th c. fell into the hands of the Arabs, under whom before the 14th c. it had dwindled to a paltry village. N. is not to be confounded with *Nisib* or *Nesib*, a village in Syria, between Aleppo and Biredshik, where the Turks under Hafiz Pasha were defeated (23d June 1839) by Ibrahim Pasha.

Ni'si Pri'us, a term of English law denoting one of the five Commissions to Justices of Assize, empowering them to try issues of fact before a jury. Before circuits came to be regularly held, all cases might be tried at Westminster; and the saving clause of the writ commanding trial began with the words 'nisi prius'—that is, *unless before* the specified day the judges should hold a county assize.

Niss'a (Turk. *Nisch*; the anc. *Naiossos*), a town in the N.W. of Bulgaria, Turkey, on the right bank of the Nissava, an affluent of the Morava, 8 miles from the Servian frontier, and 85 N.W. of Sofia. It is the converging point of three great roads, and is strongly fortified by high walls, moats, palisades, marshes, and redoubts. N. has eighteen mosques, two Greek churches, and a synagogue. Pop. 16,000, of whom nearly half are Turks and half Servians. N. was the birthplace of Constantine the Great, and the ancient capital of Servia. In the Russo-Turkish War it was captured by the Servians, January 11, 1878.

Nithard, a Frankish historian, was born about 790. His father was Angilbert, governor of the Frankish borders, and his mother Bertha, daughter of Karl the Great. He died in 853. His *De Dissensionibus Filiorum Ludovici Pii* is valuable as containing the testimony of an eye-witness in regard to what he describes. Published in 1788 by Pithou, it has been reprinted in the collections of *Historiens de France* by Duchesne and Dom Bouquet.

Nitrate of Am'yl, Medicinal Properties of. N. of A. or *amyl nitris*, produced by the action of nitric or nitrous acid on amyl alcohol, is used as an anodyne in cases of asthma and angina pectoris. It is administered by inhalation, in the form of vapour, in doses of from 2 to 5 minims. N. of A. must be used with great caution.

Nitre, Saltpetre, or Nitrate of Potash (KNO₃), is an important constituent of gunpowder (q. v.), forming from 70 to 80 per cent. by weight of this explosive mixture. It forms long striated six-sided prismatic crystals, deflagrates on hot coals, and fuses to a colourless liquid at nearly 300° C. At a red heat it loses oxygen, and is converted into the nitrite (KNO₂), which is itself decomposed at a higher temperature. In presence of a combustible body, N. loses oxygen rapidly, and is therefore valuable as an oxidising agent.

N. occurs native in various parts of India, especially in Bengal and Oude, as a white incrustation on the soil; and from this the greater part of the N. used in this country is obtained. The crystals exported to Britain are impure, and are formed by evaporation from solution. To purify these, potassium carbonate is added to the solution, when the lime present as nitrate is precipitated as carbonate. The filtered solution is then made to crystallise by evaporation and cooling, but in such a way that the formation of large crystals, which are apt to enclose within their cavities portions of the impure liquor, is rendered impossible. This is effected by continuous stirring; and such objectionable impurities as the chlorides of potassium and sodium are retained in the liquid. The *saltpetre flour*, as it is called, is then washed with small quantities of water, drained thoroughly, and dried. In France artificial N. is prepared from the nitrates obtained from *nitre heaps* or accumulations of vegetable and animal refuse with limestone, old mortar, ashes, &c. These heaps are protected from rain by a roof, but are exposed freely to a prevailing wind. They are watered from time to time with stable drainings; and the chemical action which supervenes results in the gradual formation of the nitrates of the bases present (potash, lime, magnesia, ammonia), which appear as an incrustation on the exposed face of the heap. The incrustation is scraped off, treated with potassium carbonate, which converts the whole into potassium nitrate or N., and purified as above. Peruvian or Chili Saltpetre is the nitrate of soda (NaNO₃), found in these regions of America in beds beneath the surface soil. The deposits of Tarpoca, in Peru, are estimated at seventy million tons, and a company, now being formed (1877),

proposes to take them entirely into its own hands. Owing to its deliquescent nature, the same property which renders the chlorides of potassium and sodium injurious in N., nitrate of soda cannot be used in the manufacture of gunpowder, since it would attract moisture from the air. The Peruvian saltpetre, however, is important as a source from which true N. may be obtained, since it is converted into this salt by double decomposition with chloride of potassium. The reaction is given by the equation—

The nitre is crystallised by evaporation and cooling, the more soluble sodium chloride remaining in solution. Besides being the important constituent of gunpowder, N. derives economic value as being a source from which Nitric Acid (q. v.) is prepared. For medicinal properties of N. see POTASH and SODA.

Nitric Acid (HNO₃), a transparent, colourless liquid, having when pure a specific gravity of 1.52. It freezes to a buttery consistency at a temperature of -55° C., and boils at 84° 5' C. It fuses at ordinary temperatures, and evolves heat when mixed with water. It is a powerful oxidising agent, and attacks nearly all organic substances, especially if hot and undiluted, when the red fumes of nitric oxide are frequently disengaged. With the exception of gold, platinum, and some of the rarer metals, it oxidises as a rule the simple elements also; and its compounds are for the most part soluble in water. It causes brilliant combustion when poured upon powdered charcoal, and can keep up the combustion of a red-hot lump plunged in it. In its most concentrated form, however, it refuses to act on certain substances, and in other cases acts much less vigorously than in its more diluted state. The acid may be prepared from potassium or sodium nitrate by the action of sulphuric acid. The reaction is given by the equation $\text{KNO}_3 + \text{H}_2\text{SO}_4 = \text{HNO}_3 + \text{HKSO}_4$, and similarly for sodium. The bisulphate (HKSO₄ or HNaSO₄) is made to crystallise out by evaporation and cooling. In the preparation of large quantities the sodium nitrate is the more convenient, being much cheaper, and furnishing a larger proportion of the acid. By using twice as much of the nitrate, and subjecting to a higher temperature, the normal sodium sulphate, useful in the manufacture of glass, is formed. Thus—

When heated 2HNO_3 decomposes into $\text{H}_2\text{O} + \text{O} + 2\text{NO}_2$, which accounts for the presence of red fumes of nitrate peroxide in the retort during certain stages of the preparation. *Nitro hydrochloric acid* or *aqua regia*, is a mixture of N. A. with hydrochloric acid, and is used for dissolving gold and platinum.

Medicinal Properties of N. A.—N. A., sometimes called azotic acid, is strongly corrosive, and is applied as a caustic by means of a pointed glass rod to phagedenic sores and chancres. Diluted N. A. contains 15 per cent. of anhydrous acid, and is given internally in doses of from 10 to 30 minims, generally in combination with bitter infusions and tincture of orange. N. A. is used as an injection in phosphatic calculus; and being refrigerant, tonic, and antiseptic, it is useful, when very much diluted, as a drink in febrile diseases, especially typhus.

Nitrogen (symbol N, atomic weight 14), a permanent gas, first recognised as a distinct chemical element by Rutherford in 1772. It constitutes about four-fifths of the volume of the Atmosphere (q. v.), is colourless, odourless, and chiefly characterised by negative qualities. It is not poisonous, can be respired, tubes do not support respiration, so that death speedily ensues from the absence of oxygen. In the atmosphere it serves simply to dilute the oxygen, whose vital action would be otherwise too energetic. Though it is, so to speak, characterless in the free state, it occurs widely as an important constituent in compounds of marked properties—such as strong acids, deadly poisons, important medicines, and violent explosives. Its presence in potassium nitrate or Nitre (q. v.), the chief ingredient in gunpowder, has suggested its present name (Gr. 'generator of nitre'). Formerly it was called *Azote*, from its lifeless properties. N. may be very simply prepared by burning phosphorus in air under a bell jar standing over water. The oxygen combines with the phosphorus to form phosphoric acid, which is readily absorbed by the water, and nitrogen is left behind. Otherwise than by being a necessary constituent of our air, N. has recently become more interesting as a gas widely diffused through the universe, and forming a large proportion of the composition of nebulae. See NEBULA and SPECTRUM ANALYSIS.

One of the most important of the compounds of N. is Ammonia (q. v.), which exists in small quantity in the atmosphere, and is a constant product of the putrefaction of nitrogenous matter. Its composition is NH_3 . It is a strong base, acting on acids to form important salts, in which the radical NH_4 or ammonium enters like a metal. N. forms five compounds with oxygen. Nitrous oxide, or laughing gas (N_2O), is prepared by heating nitrate of ammonia ($\text{NH}_4\text{NO}_3 = 2\text{H}_2\text{O} + \text{N}_2\text{O}$). It is colourless, has a slight odour, and a sweetish taste. It is used as an anæsthetic; but when inhaled in smaller quantities produces a kind of intoxication or abnormal hilarity, whence its popular name. Nitric oxide (NO) is formed along with nitrate of copper and water by the action of metallic copper upon dilute nitric acid. It is colourless, but forms, when brought into contact with oxygen, a red coloured gas, which appears to be a mixture of the peroxide (NO_2) and nitrous acid (N_2O_3). Nitric oxide can be readily distinguished from nitrous oxide by its inability to support combustion. Nitrous acid (N_2O_3) exists in small quantity in rain water. It may be obtained by heating nitric acid with starch, or with an equal weight of arsenious acid, and passing the evolved gas through water and chloride of calcium to purify it of any nitric acid that may be present and to dry it. The anhydrous acid is a liquid at low temperatures, boiling at 0°C ., and decomposing on volatilisation partly into nitric oxide (NO) and nitric peroxide (NO_2). It forms nitrites, which are interesting as often resulting from the decomposition of nitrates by heat. Nitric peroxide (NO_2) may be prepared by direct union of nitric oxide with oxygen, and also obtained mixed with oxygen from the decomposition of the nitrate of lead. It is a dark red gas, condensable at low temperatures; and acts as a powerful oxydising agent. Nitric anhydride, or anhydrous nitric acid (N_2O_5), may be obtained, together with chloride of silver and oxygen, by gently heating nitrate of silver in a slow current of chlorine. It condenses into transparent colourless crystals, which liquefy at 29.5°C ., and boil at 45° , decomposing at a slightly higher temperature. When brought into contact with water, the anhydride forms hydrated nitric acid (see NITRIC ACID) with the evolution of heat. The hydrous form is one of the strongest of known acids, forming by its action upon bases a series of compounds known as nitrates, which as a rule are readily soluble in water and decomposed by heat. The five oxides of N. indicate in a marked manner the chemical Law of Multiple Proportions (see ATOMIC THEORY).

Nitro-Glycerine ($\text{C}_3\text{H}_5(\text{NO}_3)_3\text{O}_9$), an oily liquid of specific gravity 1.6, prepared by acting on Glycerine (q. v.) with strong nitric acid, when three of the hydrogen atoms are replaced by three molecules of nitric peroxide. It is a violent explosive compound, detonating when struck by a hammer. When slowly heated, however, it decomposes quietly. It is the basis of several blasting compounds, for an account of which see DYNAMITE.

Nitrous Ether, Spirit of, or Sweet Spirits of Nitre, is prepared by distilling nitric acid, sulphuric acid, and rectified spirit, to which copper, in fine wire, has been added. The product is a transparent and nearly colourless fluid, with a slight tinge of yellow, of a peculiar penetrating odour, and a sweetish sharp taste. It is stimulant, diaphoretic, and diuretic, and is useful in catarrh and dropsy, especially in the dropsy which follows scarlatina, and in febrile affections. The dose is from one-half to two fluid drachms, in combination with acetate of ammonia.

Nitzsch, Karl Ludwig, a distinguished German theologian, born near Wittenberg, 6th August 1751, was appointed (1790) a Professor of Theology in the university of his native town, at which he had been educated. Having lost this appointment in 1813, he was in 1817 made Principal of the Theological Academy in the same town, a post which he held till his death, 5th December 1831. In his lectures and writings, which attracted much attention, N. sought to effect a compromise between orthodoxy and rationalism, his views regarding the work of Christ, miracles, &c., being roughly those of Schleiermacher (q. v.), but rather more orthodox. His most important works are *De Discrimine Revelationis Imperatoris et Didactica* (2 vols. Wittenb. 1830), *De Revelatione Religionis externa eademque publicæ* (Leipa. 1808), *Ueber das Heil der Theologie durch Unterscheidung der Offenbarung und Religion als Mittel und Zweck* (Wittenb. 1830). See Hoppe, *Denkmal N.'s* (Halle, 1832).—

Two sons of the above, Karl Immanuel, born 21st September 1787, died 21st August 1867, and Gregor Wilhelm, born 22d November 1790, died 22d July 1861, also gained a high reputation—the one as a preacher and theologian, the other as a philologist and archaeologist. Karl's best works are his *System der Christl. Lehre* (Bonn, 1829; 6th ed. 1851), and *Praktische Theologie* (Bonn, 1847–48; 2d ed. 1863). Gregor is best known in Germany by his *Sagenpoesie der Griechen* (Braunsch. 1852), and his posthumous *Beiträge zur Geschichte der Epiischen Poesie der Griechen* (Leips. 1862). See Lübker's *Gregor Wilhelm N. in seinem Leben und Wirken* (Jena, 1864).

Nivelles, a town in the province of Brabant, Belgium, 19 miles S. of Brussels by rail, contains the Romanesque church of St. Gertrude (1048), with two magnificently-carved pulpits, and a colossal statue, Jean de N., which strikes the hours; and has manufactures of lace, cotton and woollen stuffs, paper, and 'Waterloo relics.' The Clabecq ironworks, in the neighbourhood, employ 600 hands. Pop. (1873) 9508.

Nivernais. See NEVERS.

Nix's, in German folk-lore the name of certain dæmonic beings which resemble men in their upper parts, while in the lower they are like snakes or fishes, and live in families under water, often in crystal palaces at the bottom of the sea, or of lakes, rivers, brooks, pools, and wells. They have no souls, at least in the religious sense. They keep in glass vessels the souls of the drowned. In the present form of the N. legends, female N. are more prominent than male. These are often of human form, sometimes with fish scales, green hair or teeth, and red or green clothes. They love music and dancing, and, like the dwarfs, often help men, but take no reward. They are said sometimes to steal children and put changelings in their place. It is very probable that the N. were originally star-deities, the idea being derived from the reflection of the stars in water. See Henne am Rhyn, *Die Deutsche Volkssage* (Leips. 1874).

Nizam (derived from an Arabic word *nizam* = order, administration, which in Hindustani becomes either *N.* or *nasim*), a title applied in India to the viceroys of the Mogul empire, with special reference to their administration of criminal law and the police. In this sense it was opposed to the financial functions of the *diwan*, though both offices were commonly joined in the same hands. The Nawab of Moorsheadabad in Bengal, who yet retains his titular rank, was pre-eminently styled Nawab N.; while the Viceroy of the Deccan, who still rules at Hyderabad, has the special title of N. In the early days of British administration, the chief criminal court was called the Nizamut Adawlut. The term N. is also applied to the regular army of the Ottoman empire, as opposed to the *redifs* or reserves, the *mustafis* or militia, and the *bashi-basouks* or irregulars.

Nizam's Dominions, The, or Hyderabad State, occupy a great part of the Deccan, being enclosed between the Central Provinces and the Presidencies of Bombay and Madras. Including the tracts administered under treaty by the British (*vide* Berars), the total area is about 98,000 sq. miles; pop. about 12,000,000; revenue, about £4,000,000, of which two-thirds is raised by the officers of the Nizam; the army consists of the Hyderabad subsidiary force, 6270 strong, the Hyderabad contingent, numbering 8386, both officered by Englishmen, and about 30,000 other troops. Besides the staples of rice, wheat, and millet, the soil produces cotton and many choice kinds of fruits; the breed of horses also is famous. The minerals are coal and limestone; the manufactures metal-ware, gold embroidery, paper, and sugar; the external trade is estimated at £10,000,000 per annum. A State railway is now in course of construction from the Indian Peninsula system to the town of Hyderabad (q. v.), at the cost of the Nizam; in 1874, £871,000 had been spent, and 119 miles were open. The dynasty to which the Nizams belong is of Tartar origin. It was founded about 1724 by Nizam-ul-Mulk. The family name is Azuf Jah. At first the policy of the State was subservient to French influence, represented by the great Dupleix. The first treaty with the British dates from 1759. There have been numerous treaties since, and the Nizam has been almost continuously an ally of the British, notably during the struggle with Tippoo Sultan (1790–1800) and the Pindari War of 1817. The principle of the alliance was that the Nizam should furnish funds to support a military contingent;

but the State was misgoverned and oppressed with debt, and arrears of 'subsidy' have been repeatedly satisfied or guaranteed by cessions of territory. The last treaty was in 1853, when the Berars were 'assigned.' From the same date commenced the prosperous administration of Sir Salar Jung (q. v.), to whom it is chiefly due that the Mohammedans of Hyderabad were quiet during the Mutiny of 1857, and that the Nizam's contingent did good service in the field. The present Nizam is a minor; his name is Mir Mahbub Ali Khan. See *The Wellesley Despatches* (Oxf. 1877).

Nizām-ūl-Mulk ('the regulator of the country'), the best known title of the founder of the dynasty which still rules at Hyderabad. His proper name was Ghazi-ud-din Azuf Jah, and he was born about 1670, of Turcoman or Tartar descent. After a long life at the Delhi court under the emperor Aurungzeeb, distinguished alike in war and in political cunning, he was appointed Nawāb or Viceroy of the Deccan in 1724, and from the first established his independence. He was thenceforth entirely occupied with the struggle against the rising power of the Marhattas under the Peishwa, who took from him Malwa. He died in 1748.

Noailles, an illustrious French family, who from the 11th c. held the château and domain of N. in the modern department of Corrèze. The following merit special notice:—**Adrien Maurice, Duc de N.**, born at Paris, September 29, 1678, entered the army (1692), won a high reputation as a general in the Spanish War of Succession (1702–13), and was made president of the Council of Finance (1715), a post which he lost (1718) by his opposition to Law, the Scotch adventurer. He was created a marshal and commander-in-chief (1733); at the head of the Sardinian troops expelled the Imperialists from Italy (1734), and was defeated by George II. at Dettingen (1743). He served under Marshal Saxe at Fontenoy (1745), was despatched as ambassador to the Court of Spain (1746), and died at Paris June 24, 1766. The *Mémoires* (6 vols. Par. 1777) ascribed to N. were composed by the Abbé Millot from materials furnished by the duke.—**Louis Marie, Vicomte de N.**, grandson of the preceding, born at Paris, April 17, 1756, served through the American War of Independence with Lafayette, and married his sister. In the French Revolution N. espoused the cause of the people, sat with the Left in the National Assembly, and was elected its president (1791). Having taken a command in the army, he was defeated at Gliswel (1792), and despairing of his country's future, passed over to England, and thence to the United States, while the countess, who remained behind, was guillotined, July 22, 1794. Re-entering the French service in 1803, N. was despatched to St. Domingo, and in boarding an English corvette off Havana was mortally wounded, and died January 9, 1804.—**Paul, Duc de N.**, the present head of the family, was born in Paris, January 4, 1802, and succeeded his great-uncle, Louis François Paul, in 1824. He has written a *Histoire de la Maison Royale de St. Louis* (1843; new ed. enlarged 1856), and *Histoire de Madame de Maintenon* (1848). After 1848 he withdrew from a political, and devoted himself exclusively to a literary life. In 1849 he was elected a member of the French Academy. M. Thiers in 1871 offered him the post of ambassador to the Russian Court, but N. declined it on the plea of ill-health.

Noakolly (*Nodkhall*, 'new cut'), the chief town of the district of the same name, Bengal, British India, on a creek about 10 miles from the sea, and 170 miles E. from Calcutta. Pop. (1872) 4752.—The district of N. closes the N. of the Bay of Bengal, at the mouth of the main channel of the Ganges and the Brahmaputra, locally known as the Meghna river; area 1557 sq. miles; pop. (1872) 713,934. Mohammedans largely predominate in this tract, which has but lately been formed by alluvion. The seaboard, and especially the island of Sundeeep, was the scene of the devastating cyclone of Nov. 1st, 1876, which was followed by an equally terrible outbreak of cholera. In the year 1876–77 the total exports were valued at £250,000; the imports at £87,000. Despite the effects of the storm-wave, 571,000 cwts. of rice were exported and £84,000 of betel-nuts.

Noble Officium, a term of Scotch law, denoting the prerogatives of the Court of Session (q. v.). It is especially applied to denote the *equitable* power of that court. See EQUITY AND LAW.

Nobility. A threefold distinction between the noble, the freeman, and the slave is a primary fact in the histories of the Greeks, the Romans, and the Teutons; and a Norse myth makes the Jarl, Karl, and Thrall the offspring of three separate acts of creation. The Eupatrides, Patricians, and Eorlas were alike of immemorial antiquity, but seem to have represented an older stock of citizens, who withheld all privileges from the plebeian body that gradually gathered around them, and who, thus became an aristocracy. At Athens, long after a pure democracy had theoretically thrown open all offices to every citizen, we see Pericles, Alcibiades, and others of noble birth occupying almost as a matter of right those dignities to which Cleon found his way only by a caprice of fortune. At Rome the older nobility retained certain of their legal privileges to the last, the interrex being always an exclusively patrician officer, elected by none but patrician senators. On the extension of the other offices of state to the plebeians, a new N. arose, every descendant of a curule magistrate being *nobilis*, and entitled to the *jus imaginum*. So with the Teutons the immemorial N. of the Eorlas gave place to the new N. of the Thegnas, who sprang from the *comitatus* or personal following of a chief. This *comitatus*, answering to the *hetairoi* of Theseus and the *antrustions* of the Frankish monarchs, grew up side by side with the kingly power, and became the root of every form of N. in Western Europe. A N. of birth, like that of the Eorlas, was beyond a king's creation; such military titles as duke, marquis, or count he could confer at will; and just at the period of transition from the old to the new N. birth seems to have been less regarded than ever before or afterwards. Once established, however, the new nobles became themselves the founders of a N. of birth. The principle of hereditary transmission secured to their descendants possessions and dignities that raised their holders not only above the mass of the people, but on a level with the king himself; and, under the influence of Feudalism (q. v.), the French *noblesse* and the German *adel* came to be regarded as distinct and separate castes. With the Reformation the last traces of the old Teutonic notions of equality of birth died out. Till then many younger sons of the N. had found a career in the Church, open alike to lord and peasant; thenceforth in Protestant lands they crowded to camp and court, to the exclusion of the burghers. The wars of the 16th and 17th centuries everywhere heightened the power of the nobles, by weakening the trading and industrial classes. 'Gold' lacking the 'guinea's stamp' came more and more to be depreciated, and in 1781 we find an edict of Louis XVI. ordaining that no one could rise to the rank of sub-lieutenant in the French army without proving four generations of N. In England the development of a N. was widely different. Whereas on the Continent there was no intermediate class, except in the chartered towns, to bridge over the gulf between the baron and the peasant, here the native thegnhood, thrust down by the Norman Conquest into a secondary rank of freeholders, formed as the gentry and yeomanry the backbone of England. Nor did a N. of the Continental type grow up among the Norman conquerors themselves. Thanks to the law of William, by which every man in England was the man of the king, and to his bestowal on the peerage of a legislative authority, there arose an aristocracy, not of rank and privilege, but of political power. The English peer, in dying, transmits to his eldest son an office in the legislature of the country, which can only be held by one; his younger children are simple commoners. Hence, in Macaulay's words, 'our democracy has ever been the most aristocratic, and our aristocracy the most democratic in the world;' or, as Mr. Freeman puts it, 'our peerage is not only a rank to which any man may rise, but it is a rank from which the descendants of the hereditary holders must as a matter of course come down.' See Gneist, *Adel und Ritterschaft in England* (Berl. 1853); Stranz, *Geschichte des Deutschen Adels* (1845); and Freeman, *Comparative Politics* (Lond. 1873).

Laws Regarding N. in Great Britain.—Those who are peers of England, of Great Britain, or of the United Kingdom, have a hereditary seat in the House of Lords. Peers of Ireland and Scotland, who are not also peers of Great Britain or of the United Kingdom, can only sit in the House of Lords by election. See under ELECTION—*Election of Scottish Peers*. But peers of Scotland have their rank as such in the United Kingdom; each grade ranking next after the same grade of England. Thus, a Scotch duke is inferior in rank to an English duke, but superior to an English marquis, and superior to a duke of Great Britain

or of the United Kingdom. An Irish peer may sit in the House of Commons, but a Scotch peer cannot. If therefore a Scotch peer be not also either a peer of Great Britain, or of the United Kingdom, or one of the 16 representative peers, he cannot sit in Parliament; being the only British subject who is so disqualified. No Scotch peer can be created since the Union in 1707. A limited creation of Irish peers is allowed by the treaty of Union between Great Britain and Ireland in 1801. A peer cannot lose his nobility except by attainder; but in the reign of Edward IV. George Neville, Duke of Bedford, was degraded by Act of Parliament on account of his poverty. If accused of treason, felony, or misprision, a nobleman must be tried by his peers; but in misdemeanours a peer is tried by jury, like a commoner. Wives and widows of peers have the rank of their husbands; but a woman remarrying takes the rank of the husband of the remarriage, if her rank is dependent on marriage. Unmarried daughters of peers have the rank of their eldest brother during the life of his father.

Nocera dei Pagani, a town of Italy, in the province of Salerno, on the Sarno, 22½ miles S.E. of Naples by rail. The seat of a bishop, it contains a castle (in which Urban VI. was besieged by Carlo di Durazzo, 1385) and fine cavalry barracks, and has important cotton manufactures and a trade in cheese and cattle. Pop. (1874) 13,149. N. (Lat. *Nuceria Alfaterna*) first appears in history in B.C. 315, was captured by Hannibal (B.C. 216), and derives its modern affix from the establishment here of a body of Saracens (*pagani*) by Friedrich II.

Noctiluca, a peculiar genus of *Protozoa* (q. v.), finding its most appropriate place amongst the *Infusoria* (q. v.). It receives its name from being the cause of the *widely-diffused* or *general* luminosity of the sea. Existing in vast numbers on the surface of the ocean, these animalcules, by their phosphorescent light cause scintillations to shoot athwart the water. N. attains an average length of ¼th of an inch. Its body is somewhat kidney or peach shaped, and has a central groove, at the extremity of which is the mouth. A long filament or tentacle is situated above the mouth, and there is a single vibratile cilium by means of which the creature moves. The central protoplasm of the body is connected by thread-like processes with the outer portion, and there is a *nucleus* or *endoblast* in the former. The N. has amazing powers of reparation after injury. Reproduction is effected by *fission* or division of the body, by internal division or segmentation, and after conjugation. The only species is *N. miliaris*, which is abundant in most seas, and which emits its light by the outer layer of the protoplasmic body.

Nocturn (Lat. 'by night') was a church service anciently celebrated during the night, the name being afterwards synonymous with Matins (see CANONICAL HOURS). The name is now applied in the Anglican Prayer Book to each of the portions containing nine psalms into which the Psalter is divided, and in the Roman Catholic Breviary to each of the three portions of the service of Matins on Sundays and festivals.

Nodd'y (*Anous stolidus*), a species of *Natatorial* or swimming birds, mostly inhabiting tropical regions, found plentifully in W. Australian coasts, but of rare occurrence in Britain. It attains a length of 14 or 15 inches, and is of a dark or dusky brown, the top of the head being buff-coloured, and the bill, legs, and feet black. The N. is a dull bird, settling on ships and allowing itself to be readily captured. It is, however, a skilful fisher. Its nest is rudely constructed, and is placed either on a rock overhanging the water or on a low bush. The eggs, which are dark orange, are three in number, and are said to be very palatable.

Nodes, in the theory of sounds, are the points of a vibrating system, at which the vibrations are insensible. The simplest example is found in the case of a stretched cord, which if gently plucked at the centre will vibrate as a whole to its fundamental note. If it be plucked at a fourth of its length from either end, and at the same time its middle point be kept steady by contact with a stationary object, the cord will vibrate in two segments, and will have three N., one at the centre and the others at the ends. The musical note emitted in this latter case will be an octave higher than in the former, and by varying the position of the node or N. the various harmonics of the fundamental note are obtained. Any arbitrary vibration of a stretched cord, such

as in bowing a violin string, generally results in the production of the higher harmonics to the fundamental note, and thus altering the *quality* of the sound. In such a case there is, so to speak, a superposition of systems of N., each system being connected with a particular harmonic. In an organ pipe there are also N. or regions of rest, the positions of which depend upon the nature of the pipe. In an open pipe the principal node is at the centre, the regions of greatest agitation being the two ends. In the closed pipe the node is at the closed end. Hence in a closed pipe the distance from node to node is twice its own length, and therefore double the distance from node to node in an open pipe of the same dimensions, and therefore a closed pipe gives a note an octave lower than the note which an open pipe of the same length gives. In the case of vibrating plates or surfaces the N. are ordinarily lines curved or straight.

In astronomy the N. of a planet's, satellite's, or comet's orbit are the two points in which the orbit intersects the plane of the ecliptic. The node at which the planet passes from the S. to the N. side of the ecliptic is called the *ascending* node, the opposite one the *descending*. The longitude of the ascending node is one of the Elements (q. v.) of a planet's orbit, and is subject in all cases to a regular and continuous variation which is the result of the perturbing action of the other planets. See PRECESSION.

Nodes are swellings which occur on bones, and are formed of thickened and inflamed periosteum, separated from the surface of the bones by febrinous effusion. N. are usually the result of syphilis, struma, and rheumatism, and they are round and small like a half marble. The first symptoms are pain in the parts, aggravated by heat; swelling and apparent softening of the affected bone. The treatment consists in general constitutional remedies, appropriate to the cause, combined with counter irritation. Iodide of potassium combined with opium acts beneficially in both syphilitic and rheumatic N.

No'dier, Charles, a French author, was born at Besançon 29th April 1780, received a liberal education in classics and the older literature of his own country, and became a member of the *Amis de la Constitution* Society in 1792, before which he delivered a most precocious speech. His studies now took a wider direction, and after serving for a year or two as librarian in his native place he went to Paris, where he published some weak imitations of Goethe's *Werther*. In Paris he devoted himself to journalism, being in turns Republican and Royalist. His literary activity was immense, including works of archaeology and grammar, but his historical accounts, even of contemporary events, were singularly mendacious. In 1823 he was appointed librarian of the Arsenal, where he gathered round him the most distinguished writers of the Romantic school. Between that period and his death at Paris, 27th January 1844, N. continued to pour forth history, romance, *Souvenirs*, and *Mélanges* which, though written with elegance, are of no permanent value. See Sainte-Beuve, *Portraits Littéraires*, vol. ii.; Wey, *Vie de C. N.* (Par. 1844), and Mme. Ménessier-N., *C. N., Episodes et Souvenirs de sa Vie* (Par. 1867).

Nodosa'ria, a genus of *Foraminifera* (q. v.) having a long shell resembling a beaded rod in shape, but with the first formed chambers or segments larger than the last. *N. hispida*, a familiar species, derives its name from the small processes that project from the surface of the shell. N. is one of the *Polythalamous* or 'many-chambered' foraminifera, the new chambers being formed by a process of budding or gemmation.

Nogent-le-Botrou, a town of France, in the department of Eure-et-Loire, on the Huisne, 39 miles N.E. of Le Mans by rail. It contains three churches, the Château de St. Jean (once the residence of Sully), and tanneries and candle factories. Pop. (1872) 5884.

Noils are the short fibres separated from the 'tops' or long fibres in the combing process in the alpaca, mohair, and worsted manufactures. They are used for felting, and are also woven up in inferior cloths.

No'la, a town of Italy, in the province of Caserta, lies in a valley between Vesuvius and the Apennines, 13 miles N.E. of Naples. The remains of an amphitheatre and a valuable collec-

tion of inscriptions, preserved in the college, recall its importance in ancient times. Founded by the Ausonians, N. was taken by the Romans from the Samnites in 313 B.C., and in 216 and 215 was the scene of victories gained by Claudius Marcellus over Hannibal. The Emperor Augustus died here in 14 A.D. Many beautiful Campanian vases have been found in the neighbourhood. Here in the 4th c., it is said, church bells were first cast; the large sized being called 'Campanæ,' after the ancient province Campania, and the small 'Nolæ,' after the town. N. is the birthplace of Giordano Bruno (q. v.). Pop. (1874) 11,395.

No'li Me Tan'gere. See LUPUS.

Noll'ekens, Joseph, son of an Antwerp artist, was born in Dean Street, Soho, London, August 11, 1737. He received no general education, and to the end of life was barely able to read and write. When thirteen he became pupil to Scheemakers, the sculptor, and while with him obtained several prizes from the Society of Arts. In 1760 with scanty means he took up his abode in Rome, where by executing admirable busts of Garrick, Sterne, and others, he rapidly rose to notice. Returning to London after ten years' absence, he found abundance of remunerative work awaiting him; and he became in 1771 Associate, in 1772 Member, of the Royal Academy. Soon after, George III. sat to him for a bust. Imitative though not imaginative, painstaking if not inspired, N. rarely failed in his portraits. During his long career he found little time for high art; and though he has left several renderings of conventional mythological subjects, only one—a Venus anointing her hair, sometimes called the 'Rockingham Venus'—betrayed any originality. Of his portraits those which best display his delicacy of workmanship and gracefulness of pose are the heads of Pitt and Fox, the Prince of Wales, the Marquis of Stafford, the Duke of Bedford, the statue of Pitt for Cambridge, and that of Mrs. Howard of Corby Castle. The money earned by his talents he hoarded with extreme penuriousness; his wife, beautiful and rich, was even more miserly, and between them, by the 23d of April 1823, when he died, they had saved from his income more than £200,000. His pupil, J. F. Smith, wrote his *Life and Times* (1828). See also Cunningham's *Lives of British Painters and Sculptors*.

Noll'e Pros'equi, a term of English law, denoting the intimation by a plaintiff of his intention not to proceed further in his action, or in part of it. N. P. entitles the defendant to costs.

No'mads (Gr. *nomades*, from *nemcin*, 'to pasture') are people who have no fixed habitation, but wander from place to place in search of pasture or game. The principal nomadic nations in history are the Huns, Arabs, and Tartars. In Europe there are still the Lapps in the N., and various tribes occupying the steppes in the region of the Black Sea.

No'mansland, or **New Griqualand**, a district of S. Africa, bounded on the N. by Basutoland, on the E. by Natal, on the S. by Independent Kaffraria, and on the W. by Tambookieland. Its length from E. to W. is 125 miles, and its breadth from 40 to 75 miles, the total area being about 8000 sq. miles. N. lies on the S. slope of the Quathlamba Mountains, and in its elevated portions the climate in winter is severe. Wheat is grown in considerable quantities, and the country is also well suited to sheep and cattle. It was thinly peopled by fragments of Kaffir tribes till 1862, when the Ama-ponda chief Faku ceded his nominal right of sovereignty over a portion of it to the government of Cape Colony, who thereupon parcelled out the unoccupied land among 15,000 Griquas, who removed thither to escape the pressure of the Boers (q. v.), and among various tribes of Basutos and Fingoes. This portion is commonly known as Griqualand E. In 1876 the Griqua chief Adam Kok died, and at the desire of the inhabitants N. was then annexed to Cape Colony. The pop. in 1875 amounted to 62,341.

Nom'bril (Fr. for *Pombri*, from Lat. *umbilicus*, 'navel') in Heraldry a point halfway between the fesse and middle base points of an escutcheon.

Nome (Gr. *Nomos*), a name given to certain Greek chants, the nature of which is obscure.

Nom'inalism is the name given to the theory of those who hold general terms to be mere names. REALISM, on the other hand, asserts that they are objective realities. The controversy between Nominalists and Realists is commonly said to

have developed with Scholasticism; but it is really as old as Plato, to whose doctrine of ideas Aristotle opposed his dialectic science of names. Roscellin, a canon of Compiègne, commenting on the quarrels of Platonists and Peripatetics over genera, founded N. by maintaining that when, for instance, we unite Jupiter, Mars, Saturn, &c., under the general name *planet*, this is a mere mental and arbitrary bond, existing only in ourselves. Others quickly rejoined that there really exists something in which are combined all the common attributes of these individuals, whilst it possesses none of their distinguishing properties. The discussion was soon mixed up with theology, and was conducted for centuries with incredible acrimony, sometimes leading to actual bloodshed. Among the most distinguished Nominalists were William of Occam, John Buridan, Robert Holcot, Henry of Hesse, Raymond of Sebonde. Of the Realists we may cite William of Champeaux, Thomas Aquinas, Walter Burleigh, Thomas of Strassburg, Thomas of Bradwardine. A third and middle School, more reasonable than either of the others, was founded by Abelard, who, adopting the theory of Conceptualism, gave reality to both individuals and universals—to the first, essential existence, to the second, ideal. Besides ordinary histories of philosophy, consult Erner's *Ueber Nominalismus und Realismus* (1842).

Nom'inative. See DECLENSION.

Non-Appear'ance, a term of English law denoting that a defender in a suit or action has not entered an appearance before the court. See DEFAULT.

Non-Assump'sit, a term of English law denoting a plea of denial by a defendant in an action for breach of contract not constituted by deed.

Non-Commissioned Officers in the British Army (sergeant-majors, quartermaster-sergeants, farriers, drummers, trumpeters, &c.) belong to an intermediate rank between the commissioned officers and the rank and file, and have the charge of the latter in barracks and off parade. Corporals only in the Household Cavalry belong to this grade. (N.-C. O. may be reduced to the ranks by a court-martial or by the colonel or commandant of a regiment, but can receive no lighter punishment while holding their posts. Those who are in possession of first-class certificates of education, including English history and general geography, may obtain regular commissions on passing a professional examination. The pay of a sergeant-major varies from 3s. 3d. to 4s. 4d., of a sergeant from 1s. 11d. to 2s. 11d. The number of N.-C. O. in the regular force in 1877 was 13,252, or including the forces in India 17,920.

Nonconform'ists, a name which is sometimes applied to Protestant Dissenters in England generally, and sometimes to the Independents (q. v.), properly belongs to the Presbyterian, Independent, and other non-Episcopal ministers who held benefices by authority of the Parliament during the Commonwealth, and were deprived of them by the Parliament on the Restoration; and especially to those who resigned their livings rather than conform to the terms of the Act of Uniformity, passed August 24, 1662. The number of these last has always been represented by non-Episcopal writers as amounting to 2000; Episcopal writers, on the other hand, maintain that the number was very little, if any, over 800. See Blunt's *Dict. of Sects*, &c. (1874).

Non-Effective Services Charges in the British Army and Navy Estimates comprise rewards for services, pay of general and retired officers, half-pay, pensions to widows and for wounds, out pensions, and all expenses for which a return in active service is not expected. In the estimates for year ending 31st March 1877 they amounted to £2,245,300 in the army, or $\frac{1}{4}$ th of the total charge; and to £1,855,821 in the navy, or nearly $\frac{1}{4}$ th of the total charge.

Non-En'try is, in Scotch law, a Casualty of Superiority (q. v.) which falls to a superior when the heir of a deceased vassal neglects to have himself entered with the superior.

Nones (Lat. 'ninth') was the Church service anciently observed at the ninth hour, or three o'clock in the afternoon. See CANONICAL HOURS.

Non Est Invent'us, in English law, is the sheriff's return to a writ, when the defendant is not to be found in his bailiwick.

Nonjurors comprehended the Episcopalian party which declined to take the oath of allegiance to William and Mary at their coronation. Holding that passive obedience was due from subject to sovereign, they preserved their allegiance to James II. Sancroft the Primate, eight bishops, and 400 of the inferior clergy were among the original recalcitrants, and (February 1, 1691) being still obstinate, he and five of the bishops were deprived of their sees. See Macaulay's *History of England*.

Non-Residence, in English ecclesiastical law, is the offence committed by the incumbent of a benefice in unduly absenting himself from the place of it. 1 and 2 Vict. c. 106, regulates the penalties for N.-R. An incumbent absenting himself, without leave from his bishop, for more than three months, but for not more than six months, forfeits one-third of the annual income. An absence of from six to eight months causes a penalty of one-half of the income; of one year, three-fourths of the income. Certain officials are exempted by the Act 1 and 2 Vict. c. 107—heads of colleges at Oxford and Cambridge, the head masters of Eton, Westminster, &c.

Non-Suit, an English law term. When a plaintiff in a jury trial so chooses, he may allow a verdict and judgment to be entered for the defendant. He is then said to be *non-suited*. He may bring a new action under a N.-S., but he must first pay the costs of the previous one.

Nootkas, or **Ahts**, the name of the Indians of Vancouver's Island, comprising the Ahts proper (3500) who inhabit the W. shores of the island, the Quakwilt (3000), scattered along both sides of this island and on the mainland, and the Cowichans in the E. of the island, numbering 7000. The Cowichans have been partly civilised by Protestant and Roman Catholic missions. *Nootka Sound*, on the W. coast of Vancouver's Island, is 10 miles long, and has a breadth of 500 yards.

Nord, the most northerly department of France, extends between the Belgian frontier and the departments Pas-de-Calais and Aisne, and has a coast-line of 25 miles on the Straits of Dover. Area, 2193 miles; pop. (1870) 1,447,764. It is watered by the Scheldt, Sambre, Scarpe, &c. The surface is flat except in the S., where the chief height is Mont Cassel, 361 feet high. Along the coast the surface is in great part marshy, lying little if at all above the sea-level, but is maintained in an arable state by a system of drainage called *Watteringues*. Other parts of the country are regulated in drainage by a system of canals, windmills, and dykes, under government care. The chief products are wheat, hemp, beetroot, rye, hops, and garden fruits. A large amount of dairy produce, and of mutton, wool, &c., is sent to the Paris markets. N., part of the old province of French Flanders, is next to that of the Seine the most populous, the most advanced in education, and commercially the most prosperous among the departments of France. Lille is the capital, and other towns are Douai, Cambrai, Dunkerque, and Valenciennes.

Nordcap, the most northerly cape of Europe, under 71° 11' 40" N. lat., situated on the Norwegian island of Magerö, is formed of three perpendicular cliffs rising 1020 feet above the sea. The mean temperature is at freezing point. To the S.E., on the Varangerfjord, is Nordkyn or Kynrodden, the farthest N. point on the Continent.

Norden, a town of Prussia, province of Hanover, on a canal 16 miles N. of Emden, and 24 from the North Sea. It is a well-built town, and has considerable trade in horses and cattle. The industries are brewing, distilling, boat-building, and the manufacture of yarn and tobacco. In 1871, 1372 ships of 25,352 tons entered and cleared the port of N. Pop. (1875) 6199.

Nordenskjöld, Nils Adolf Erik, a celebrated Swedish naturalist, born 18th November 1832 at Helsingfors, where his father was Professor of Mineralogy, was appointed professor of the same science at Stockholm in 1858. After accompanying (1858 and 1861) the two expeditions to Spitzbergen led by Otto Torell, he himself led two others (1864 and 1868), in the first of which he described Gillisland, marked on the maps as King Carl's Land, and in the second reached 81° 42' N. lat., the highest point hitherto gained by sea. During these voyages N. fixed astronomically the position of eighty places in the Spitzbergen Archipelago, and made valuable geological and other collections. In

1870 he visited Greenland, whose inland ice he traversed farther north than any previous explorer, and discovered in the S. of Disco Island the three largest meteoric stones yet found—5, 10, and 25 tons' weight respectively. See his *Redogörelse för en expedition till Grönland aar 1870* (Stockh. 1871). In 1872 he led the fifth Swedish Arctic expedition. With Lindström, Stuxberg, and others, N. left Tromsø, 8th July 1875, made scientific researches on Novaia Zemlia from 23d June to 2d August, passed the Yugor Strait into the Kara Sea, reached the mouth of the Yenissei on the 15th August, sailed up that river for some distance, and then travelled overland to St. Petersburg, having opened the passage to the Siberian rivers, and proved that the Kara Sea was not a 'great ice-house.'

Nor'derney, one of the E. Frisian islands, included in the Prussian province of Hannover, lies in the North Sea, 4½ miles N.W. of the coast of E. Friesland, with which it is connected at low-water by passable sands. Length, 3 miles; breadth, 2½ miles; area, 5½ sq. miles; pop. (1875) 769. It is surrounded by rows of white sand-hills, some of which are 53 feet high, and between them are little valleys laid out in gardens. The inhabitants occupy a little village in the S.W. corner, and live by fishing and receiving visitors. N. is the oldest (since 1797) and most frequented sea-bathing place on the German coast of the North Sea. On the W. the island is protected by masonry and dykes against storms, which carried away considerable tracts in 1855 and 1858. During the bathing season (15th July—15th October) N. is in regular communication with Hamburg, Bremen, Emden, Geeste-münde, Wilhelmshaven, and Norden.

Nordhausen, a town of Prussia, in the province of Saxony, lies among the S. offsets of the Harz, on the Zorge, a small affluent of the Ilme, 50 miles W. of Halle by rail. It consists of an old or upper town, with a *Rathhaus* and three squares, a new or lower town, and several suburbs. N. has a Roman Catholic cathedral, 6 other churches, a gymnasium, and a *Real-Schule* of the first rank. The chief industries are the making of brandy (50 establishments), the manufacture of chicory, chemicals, oil, tobacco, cottons, woollens, and leather, iron-founding, and brewing. There is large trade in cattle. The Empress Adelheid here founded a monastery in 943. In 1220 N. became a city of the Empire, fell to Prussia in 1802, was joined to Westphalia in 1807, and in 1815 was restored to Prussia. Pop. (1875) 20,183. See Girschner, *N. und Umgegend* (Nordh. 1866).

Nördlingen, a town of S. Germany, in Bavaria, on the river Eger, 70 miles E. by N. of Stuttgart by rail. It is surrounded by old walls and towers, and has a fine *Rathhaus*, also a Catholic and two Protestant churches, one of which is a good specimen of the later Gothic style. N. manufactures machinery, linens, woollens, and carpets; tanning, brewing, and a trade in cattle, feathers, and corn are also carried on. Pop. (1875) 7079 (¾ Protestants). Here Ferdinand of Austria defeated 6th and 7th September 1634 a Swedish army under Bernhard of Weimar. See Mayer, *Die Stadt N., ihr Leben und ihre Kunst im Lichte der Vorzeit* (Nördl. 1876).

Nore, a sandbank at the mouth of the Thames, 3 miles N.E. of Sheerness, is marked by a floating light 33 feet high, placed there in 1734. The mutiny that broke out in the fleet stationed at the N., May 27, 1797, blocked the trade of the Thames, and was only suppressed June 13, when several of the mutineers (including the ringleader, Richard Parker) were executed at Sheerness.

Norfolk, a maritime county in the E. of England, bounded N. and E. by the North Sea, S. by Suffolk, and W. by Cambridge and Lincoln. Area, 2116 sq. miles; pop. (1871), 438,656. The coast-line (about 90 miles) is generally low, and subject to great encroachments by the sea, but by means of embankments upwards of 4000 acres have been reclaimed from the Wash (q. v.) since 1850. The surface is uniformly level, and the western portion of the county is included in the great Bedford Level (q. v.). N. is watered by the Yare (52 miles), with its affluents the Wensum (47), Waveney (49), and Bure (50), and by the Ouse (q. v.) and its tributaries. Improved farming has effected an immense change in this county, which a century ago was more than one-half barren heath. In 1876 there were 449,758 acres under corn crops, 206,445 under green crops, 169,311 in clover, sanfoin, and grasses in rotation, 234,800 in

permanent pasture, and 44,251 woods. There were also 60,020 horses, 103,699 cattle, 661,164 sheep, and 85,888 pigs. The chief crops are barley, wheat, turnips and swedes, mangold, oats, and beans. The N. breeds of cobs and cart-horses have long been famous. Six members are returned to Parliament. Norwich is the capital; other towns are Yarmouth, Lynn, Thetford, and East Dereham. See F. Blomefield's *History of N.* (11 vols. Lond. 1805-10).

Norfolk, a seaport of Virginia, U.S., is situated on the Elizabeth River (an arm of Chesapeake Bay), 7 miles N.E. of Portsmouth, with which it is connected by ferry. It has numerous churches and public buildings, two theatres, twelve banks, and ten newspapers; and, as the largest naval station in the Union, possesses a dry-dock (constructed at a cost of \$974,536), four building-slips, and a navy-yard of 109 acres. The imports (returned with those of Portsmouth), amounted in 1875 to \$18,929; the exports to \$5,243,986; and there entered the two ports 24 vessels of 13,299 tons, and cleared 106 of 49,332 tons. The manufactures are unimportant. Pop. (1870) 19,229.

Norfolk Island is in the Pacific Ocean, in 29° 3' S. lat., 167° 58' E. long., 1050 miles N.E. of Sydney, and is a dependency of New South Wales. The island measures 5 miles in length by 2½ miles in breadth, and has an area of 8607 acres. The coasts are bold, and there is no safe anchorage. The island is hilly, well watered, and fertile, producing fruits and vegetables in profusion, but is not so well adapted for the growth of cereals. The magnificent N. I. pine (*Aracaria excelsa*) is a striking object in the landscape. N. I. was discovered by Captain Cook in 1774, and was a British penal settlement from 1788 to 1807, and again from 1825 to 1855. In 1856 the descendants of the mutineers of the *Bounty* were removed from Pitcairn Island (q. v.) to N. I., and still form about half of its population of 600. N. I. is the headquarters of the missionary Bishop of Melanesia (q. v.), and has a college for training Melanesian youths as teachers and missionaries.

Noric Alps. See ALPS.

Normal Schools. See TRAINING SCHOOLS AND COLLEGES.

Norman Architecture, otherwise known as Earlier or Round-Arched Gothic, is the name given to a variety of the Romanesque, which, introduced into England by the Normans at the time of the Conquest (1066), had a brief but vigorous existence in that country till the close of Henry II.'s reign (1189), or at latest till that of Stephen (1154). Previous to the Norman period there already existed in England that style of architecture known as the Saxon; but as this had merely been derived from the Continent by a rude imitation of the styles prevailing there, the difference between the Saxon and Norman is not generic, the latter being at once a grander and more elegant development of those principles which in the former found rude and incomplete expression. The characteristic of the Saxon is massive simplicity. The most common form of the early Saxon churches was that of the Basilica, a simple oblong, with a portico and ambulatory. The outer walls were of immense thickness and had no buttresses, the pillars were very short and massive. Already during the reign of Edward the Confessor, however, the intimate connection subsisting between the English and Norman courts, and the introduction of Normans into the highest stations of the English Church, produced an imitation of the Norman style, to be seen in the Abbey Church of Westminster and in that of St. Peter at Gloucester, both erected during this period, and prepared the way for its complete adoption. In N. A. the rounded arch and circular pillar are still preserved, and in both it and the Saxon there is a total absence of pediments and pinnacles, tabernacles, or niches with canopies; but the windows of the Norman edifices are somewhat enlarged, the columns are higher in proportion to their diameter, and a great variety of ornamental mouldings cover what in the Saxon style are plain surfaces. The principal change noticeable in N. A. is the loftiness of the interior, which now consists of a triple range of (1) pierarch, (2) triforium, and (3) clerestory. Though this complex arrangement of the arch marks an entire departure from the Grecian style, it was not till the Later or Pointed-Arched Gothic period that in its employment a true union and harmony of parts was attained. The principle of verticality, which the arch had introduced was as yet in the N. A. only displayed in the augmented

height of the building. There is no subordination or connection of the parts. The string-courses which separate the pier-arches from the triforium and the latter from the clerestory are unbroken, while the arcades of the two latter frequently do not harmonise with the range of the pier-arches. The principal kind of exterior decoration on a large scale employed in N. A. is that called arcades, which consists merely in covering the surface with tiers of small columns and arches, these tiers often rising above one another to a considerable height. Good examples of this kind of work are to be seen in the two transept towers of Exeter Cathedral, the front of Castle Acre Priory, the Tower of Bury St. Edmunds, the S.W. wing of Ely Cathedral, and the front of Lincoln Cathedral. In the general plan of Norman churches there is no essential variation from the usual arrangement. (See CHURCH.) It is to be kept in mind, however, that although traces of N. A. are scattered all throughout the kingdom, there are few structures which retain this style throughout, and do not exhibit additions of later date. Besides the edifices above mentioned, the best specimens of N. A. are to be found in the older portions of Canterbury, Durham, Gloucester, Rochester, Chichester, Norwich, Winchester, Peterborough, and Oxford Cathedrals.

Normandy, an old province of France, bounded N. and W. by the English Channel, E. by Picardy and Ile-de-France, and S. by Orléanais, Maine, and Bretagne, had an area of 11,397 sq. miles, and was subdivided (1790) into the departments of Seine-Inférieure, Eure, Orne, Calvados, and Manche. Rouen was the capital. The *Gallia Lugdunensis II.* of the Romans, and later a portion of Neustria, N. received its name from the Northmen (probably Danes), after Charles the Simple, by the Peace of St. Clair-sur-Epte (912), had ceded to Rolf the Ganger the land lying between the Seine, Epte, and sea. Though to their French neighbours the Northmen (now Normans) were still 'pirates and heathens' till the close of the 10th c., yet under Rolf's grandson, Richard the Fearless (942-996), they gradually adopted French Christianity and feudalism. The old Norse freedom became extinct; the Norse language survived only at Bayeux and in such local suffixes as *gard*, *tot*, and *buf* (by); and the Abbey of Bec was but one of the countless monasteries that arose throughout the land. William the Conqueror (q. v.), the seventh duke, united N. with England (1066); from him it was wrested by Robert, his eldest son (1077), to be reannexed by Henry I. (1105); and in the reign of John, Philippe Auguste laid claim to it as a fief of France, and conquered it (1203-4). After the battle of Agincourt N. was again held by England from 1417 till 1450, when the last foot of Norman ground was lost by the surrender of Cherbourg (August 12) to Charles VII. by the Duke of Gloucester. See Palgrave's *History of N. and England* (4 vols. 1851-64); Freeman's *History of the Norman Conquest* (5 vols. 1867-76); and Mrs. Macquoid, *Through N.* (1874).

Norns (Old Norse, *Nornir*). See NORTHERN MYTHOLOGY.

Norristown, a town of Pennsylvania, U.S., on the river Schuylkill, and in a rich farming and mining district 16 miles N.W. of Philadelphia by rail, has seven cotton and woollen mills, several large ironworks, three blast-furnaces and rolling-mills, &c. There are here published three daily and four weekly newspapers. Pop. (1870) 10,753.

Norrköping, a town of Sweden in the län of Linköping, near the mouth of the river Motala (here crossed by four bridges) and the Baltic bay Braaviken, 89 miles S.W. of Stockholm by rail. It is regularly built and has wide streets, the finest of which contains a statue of Karl XIV., modelled by Schwanthaler. There are three churches, of which St. Olaf's is the most noteworthy. N. is, next to Stockholm, the most important manufacturing town in Sweden. The chief manufactures are cloth, cottons, hosiery, lucifer matches, tobacco, flour, leather, soap, and oil. There is an excellent harbour, and new docks are being constructed. Copper, iron, corn, and wood are the chief exports. To the N. are the large ironworks and cannon-foundry of Finspaang. In 1604 N. was the seat of a diet at which Karl IX. resigned the Swedish crown in favour of his son Gustaf Adolf. Pop. (1874) 26,365.

North, Frederic Lord, was born April 12, 1732, educated at Eton and Oxford, travelled for three years in Germany, Italy,

and France, and on his return to England entered Parliament. In 1759 he became a Commissioner, and in 1763 a Lord of the Treasury, from which in 1769 he passed to the Chancellorship of the Exchequer and the Leadership of the House of Commons. On the resignation of the Duke of Grafton (1770), N. became Prime Minister, and his period of office was marked by a complete subjugation to the will of George III. The King gradually absorbed the entire patronage of Government, and attached to his cause a party bound by the ties of obligation. N. became 'the mere mouthpiece of the king.' He obeyed him in his blind and obstinate policy in connection with America until he was compelled in 1778 to drop the claim of colonial taxation, and in 1782, when the victory of Saratoga alarmed England, he resigned his office in despair. In the following year occurred 'the most unscrupulous coalition known in our history.' N. took office with Fox, but it was broken up in a few months. In 1789 N. made his last public appearance to combat the ministerial project of the regency. He died blind, 5th August 1792. N. was a cultivated, good-humoured man, who, if he had acted in politics according to his own prevision of things, would not have been associated with one of the most disgraceful episodes in English history. See Macaulay's *Chatham*, Lord Brougham's *Statesmen of the Time of George III.*, and *Correspondence of George III. with Lord N.* (2 vols. Lond. 1867).

Northallerton, a market-town of England, capital of the North Riding of Yorkshire, stands near the left bank of the Wiske, 29 miles N.N.W. of York by rail. It contains four churches, a grammar school, mechanics' institute, and the ruins of the palace of the Bishops of Durham, an Austin priory (1341), and a Carmelite priory (1354). Handloom weaving, brewing, tanning, and brickmaking are the chief industries. N. returns one member to Parliament. Pop. (1871) 5249. At Cowton Moor, in this parish, was fought the 'Battle of the Standard,' August 22, 1138, in which David I. (q. v.) was defeated, with a loss of 10,000 followers, by an English army mustered by Archbishop Thorstan. The standard, from which the battle got its name, was a pole surmounted by the consecrated Host, decked with the banners of SS. Cuthbert of Durham, Peter of York, John of Beverley, and Wilfred of Ripon, and fixed in a four-wheeled car.

Northampton, a town of England, capital of Northamptonshire, on the left bank of the Nen, 67½ miles N.N.W. of London by rail. Of its seven Anglican churches, the chief are the cruciform St. Giles, All Saint's (rebuilt by Wren, 1680), the round Templar church of St. Sepulchre (restored by Scott, 1865), and the fine Norman church of St. Peter's. Other buildings are the Roman Catholic Cathedral (designed by Pugin, 1864), the Gothic townhall (1864), Italian corn-exchange (1851), county hall, chapels, barracks, infirmary, &c. The principal manufactures (which have grown very much within the last seven years—1870-77) are boots and shoes (employing 8000 men), leather (450 men), and lace and hosiery (260 women), while breweries, malt-kilns, brass and iron foundries, flour and paper mills, also afford employment. N. returns two members to Parliament. Pop. of parliamentary borough (1871) 45,080. Burnt by the Danes in 1010, N. was the scene of the parliament that ratified the 'Treaty of N.,' acknowledging the independence of Scotland (1328), and of the defeat and capture of Henry VI. by the Earls of March and Warwick, July 10, 1460. In the 11th c. it had a strong castle and embattled walls, demolished in 1662.

Northampton, a town of Massachusetts, U.S., on the Connecticut River, 17 miles N. of Springfield by rail, contains eight churches, thirty-two schools, six banks, the State lunatic asylum (1855), and the Clarke Institution of Deaf Mutes (1867). It has two newspapers, and manufactures of sewing-machines, cutlery, baskets, woollen and cotton goods, paper, &c. Pop. (1870) 10,160.

Northamptonshire, a midland county of England, bounded N. by Leicester, Rutland, and Lincoln, E. by Huntingdon and Bedford, S. by Buckingham and Oxford, and W. by Warwick. Area, 984 sq. miles; pop. (1871) 243,891. The surface of N. is undulating, rising to 800 feet in Arbury Hill, near Daventry. The Nen and Welland, its principal rivers, have a respective length within the county of 60 and 50 miles. Near Naseby also spring the Upper Avon and one head of the Ise. N. is a great grazing and dairy district. In 1876 there were 177,773 acres

under corn crops, 41,803 under green crops, 37,120 in clover, sanfoin, and grasses in rotation, 277,199 in permanent pasture, and 24,142 woods.—There were also 21,503 horses, 110,188 cattle, 514,758 sheep, and 30,260 pigs. The chief crops are wheat, barley, turnips, swedes, oats, and beans. Boot and shoe making forms an important industry. Four members are returned by this county, the chief towns of which are Northampton and Peterborough. Among its antiquities are Fotheringhay Castle and Burleigh House.

North Berwick. See BERWICK, NORTH.

Northbrook, Thomas George Baring, Earl, an English and Indian statesman, was born in 1826, educated at Christ Church, Oxford, where he graduated in 1846, was private secretary to Sir Charles Wood at the India Board and at the Admiralty, entered Parliament for Penryn and Falmouth in the Liberal interest in 1859, was Under-Secretary of State for India from 1859 to 1861, and Under-Secretary for War from 1861 to 1866. In the latter year he succeeded his father as second Baron N. From 1872 to 1876 he filled the post of Governor-General of India, and was created earl on his return. His period of office was marked by the successful struggle with the famine in N. Bengal, the deposition of the Guicowar (q. v.), and the auspicious visit of the Prince of Wales. It was his merit to bestow special attention on questions of finance and internal administration. See BARING.

Northcote, Sir John, an English politician and patriot, was the eldest son of the Sheriff of Devon, and was born early in the 17th c. He was elected to the Long Parliament for the village of Ashburton in 1640, and from the first was one of the small party who sought a *via media* between the extremes of monarchic absolutism and Puritan despotism. When the Civil War broke out he sided with the Parliament, helped to organise the Devonshire Militia, was proclaimed a traitor by the King in 1642, took part in the defence of Plymouth, shared in the defeat at Modbury (27th Feb. 1643), was made prisoner by the Royalists in 1644, but was soon after exchanged. N. fell under the suspicion of the Cromwellian party in 1646, was 'secluded' before the trial of Charles, was passed over by Cromwell in the New Communion of Peace for Devon (1650), was re-elected to Parliament during the rule of Richard Cromwell, and was a member of the Convention that restored the monarchy. He died in 1676. During his attendance in Parliament he made notes of all the memorable debates—those on ship-money, the impeachment of Strafford, the levying of war against the King, the Scots articles, and the revision of the canons. N.'s valuable *Notebook* was published by Mr. Murray, under the editorship of Mr. A. Hamilton, in 1877.—**Sir Stafford Henry N.**, eighth baronet of the name, was born in London, 27th October 1818, and educated at Balliol College, Oxford, taking a first class in classics and a third in mathematics. He was called to the bar in 1847, entered Parliament in 1855 as a member for Dudley in the Conservative interest. N. was private secretary to Mr. Gladstone when the latter was President of the Board of Trade, and in finance is a faithful disciple of his great master. In 1859 he was appointed Financial Secretary to the Treasury, in 1866 President of the Board of Trade, in 1867-68 Secretary of State for India, and in 1874 Chancellor of the Exchequer, a post which he held till April 1880. N. takes a deep interest in art and education, and is a prudent and sober legislator. As leader of the House of Commons he displays good sense, and is not deficient in spirit or courage, but he lacks the artful rhetoric and witty cynicism of his dextrous predecessor.

North-East and North-West Passages are the names given to the sea-routes which lead through the Arctic waters to the regions N. of the Asiatico-European and American continents respectively. It was hoped by the mercantile powers of western Europe that by discovering such routes, a shorter way to the Pacific and Indian Oceans might be laid open. The usurpation by the Spaniards and Portuguese of the exclusive right to the trade in these waters roused the energies of the northern nations to search for new passages. In the end of the 15th and the beginning of the 16th c., the voyages of Cabot, Gomez, Cartier, Frobisher, &c., though unsuccessful in finding a N.W. passage, resulted in important geographical discoveries along the N.E. coast of America. The English then turned their attention to the discovery of a N.E.

passage, and despatched three ships under Sir Hugh Willoughby and Richard Chancellor, who reached the S. end of Nova Zembla and were then forced to return. The former and the crews of two of the ships were frozen to death at the mouth of the Dwina; Chancellor made his way to Archangel. Other two expeditions, under Burroughs in 1556 and Pet and Jackson in 1580, were fitted out, but beyond extending our geographical knowledge, did nothing towards solving the problem. Towards the close of the c. the Dutch entered the field, and part of their small fleet managed to sail through the Sea of Kara to the Gulf of Obi. One of their ships, under Barentz, reached the N. end of Nova Zembla, but was then forced to return. In 1597 Barentz and Ryp made further attempts in this direction, discovering Bear Island and Spitzbergen, and sailing round the N.E. extremity of Nova Zembla. Soon after, however, Barentz' ship was hemmed in and crushed by the ice; and he and his companions wintered in a small hut erected on the island. In the succeeding spring, after a journey of incredible hardships, to which Barentz succumbed, the survivors made their way to Lapland. Later attempts to find an open passage have been as unsuccessful. The first to round Nova Zembla completely was Karlsen, a Swedish captain, who effected it in 1871, and who found the hut of Barentz with everything in it exactly as it had been left 274 years previous. In 1876 the locality was completely explored by Charles Gardiner, an English yachtsman, but the hut had disappeared. The idea of a N.E. passage is now abandoned; for even could a vessel manage to reach Behring's Strait, there would be no gain in time, especially since the opening of the Suez Canal. Polar research has been busy, however, in the latitudes N. of Spitzbergen during recent years; and certain eminent geographers regard this as the only feasible route to the N. Pole. The discovery of Franz-Josef Land by the Austrian expedition under Weyprecht and Payer, though not directly connected with the discovery of the N.E. passage, deserves a passing notice.

The failure of all attempts to reach the Pacific or the Pole by the North Cape revived the hope of discovering a N.W. passage. In 1585 some London merchants sent John Davis on an expedition up the W. coast of Greenland. He made in all three different voyages, discovered Davis Straits and Cumberland Island, and reached a latitude of 72°. The Muscovy Company despatched two expeditions in 1602 and 1606, but they failed to push as far north as Davis. In 1608 Hudson, in the employ of the Dutch, explored part of the North American coast, discovering Hudson River and New York Bay in his search for a western passage; but two years later he was sent out again by the English, and discovered Hudson Straits and Hudson Bay. Sir Thomas Button, Gibbons, Bylot, and Baffin opened up the intricate system of straits and sounds to the north of British America still more; and their efforts were well supplemented towards the middle of the 17th c. by Jens Munk, Fox, Middleton, Smith, Wood, &c. After 1650, no further attempt was made till the beginning of the present century. Meanwhile, however, the Russians had slowly been extending their power across Siberia, and had been gradually adding to our knowledge of its geography. Behring, Tchirikov, Krupischev, Kotzebue, Wrangle, Lutke, and others, are among the names of the Arctic navigators of the 18th c. In 1818, search for the N.W. passage was resumed under Sir John Ross. We cannot do more than name some of the host of navigators who followed:—Sir Edward Parry, Admiral Beechey, Back, Dease, Simpson, Rae, Sir John Franklin, Captain Kellet, Sir James Ross, Sir Robert M'Clure, Admiral Ommanney, Captain Kennedy, Sir L. M'Clintock, Sir Edward Belcher, Lieutenant Bellot, Admiral Inglefield, Drs. Kane and Hayes, and Captain Hall. By their discoveries the numerous islands with their separating straits which lie to the north of America are now with tolerable accuracy laid down on our maps. The N.W. passage discovered by M'Clure is between Banks and Prince Albert Lands, connected with Baffin's Bay through Prince of Wales Strait, Melville Sound, Barrow Strait, and Lancaster Sound. (For the details of his voyage see M'CLURE.) Captain Hall of the United States pushed his way far up the west coast of Greenland in 1871, but succumbed, like Franklin, to the rigours of an Arctic winter. His grave, at a higher latitude than had ever been attained before, was visited and a monument erected over it by the Arctic Expedition fitted out by the English Government in 1875, and commanded by Captain Nares. See POLAR RESEARCH.

Northern Circars (*Sarkar* = government, province, an administrative division of territory in India under the Mohammedans, now obsolete). The N. C. were five in number, lying along the coast of the Bay of Bengal, bounded W. by the Deccan, N. by Orissa, and S. by the Carnatic. They occupied an area of about 30,000 sq. miles, and having been ceded to the British in 1765 by the Mogul emperor, formed the nucleus of the Madras Presidency. The term Circar is in universal use among the natives of India to express in an impersonal and fatalistic way the supreme power of the British Government.

Northern Mythology. The Mythology (q. v.) of the North Teutonic peoples is chiefly known from the literature of the remote Norwegian colony of Iceland (q. v.). The main source of knowledge is the *Eddas* (q. v.). In these we are told that in the beginning of time there lay to the N. of the great abyss Ginnungagap a region named Niflheimr (q. v.), the land of mist and snow, and to the S. Muspellheimr, the burning world, guarded by the flaming sword of Surtr against all who had no heritage therein. The warm winds from Muspellheimr meeting the cold blasts of Niflheimr, there arose an immense giant, Ymir, and from the melting ice came forth the cow Audhumla, who produced Buri by licking the rimy rocks of Niflheimr. From Buri sprang the Æsir (q. v.) or good gods, Odin, Vili, and Ve, who slew Ymir and all his race but two. These were cast down to Utgard, and became the first parents of the evil race of the Jotuns or frost-giants. With Ymir's body Odin built the world, of his blood he made the ocean, of his flesh the earth, of his bones the mountains, of his hair the forests. His skull was raised aloft to be the firmament of heaven, in which were fixed the sun, moon, and stars, formed from the fires of Muspellheimr. Odin the *Allfödr* now created the first two human beings, Ask and Embla, giving them a mortal body and an immortal soul, and placing them in Midgard, made of the eyebrows of Ymir; while he with the other Æsir ascended to Asgard, to live in the glorious palace of Valhalla. The whole universe rested on the sacred ash tree Yggdrasil, at whose root sat the three Nornir or goddesses of fate, Urd ('what has passed'), Verdandi ('what is being born'), and Skuld ('what is to come'). While Odin was the All-father, he was also the God of Battle (*Valfödr*), requiring bloody sacrifices. The brave who fell on the battle-field were led by the Valkyjur (q. v.) to Asgard, there to fight every day from dawn till meal-time, and after that to ride back to Valhalla, and sit down to drink. Those who died of disease or old age went to the abode of Hel (q. v.), but murderers and perjured men were consigned to Ná, a hell horrible with wretched adders, from whose heads poured streams of venom, in which these should for ever wade. After Odin, the chief Æsir were Frigg, his wife, who knew, but kept secret, all fate; Thor (q. v.), the Thunderer, his first-born son; Balder (q. v.), the Beautiful; Freyr (q. v.), Freya (q. v.), Bragi (q. v.), Tyr (q. v.), Heimdall, and Ægir, the god of the sea. The fair-faced Jotun Loki (q. v.), whom Odin had spared, grows up and renews the old quarrel between the Æsir and the frost-giants, or powers of evil. The latter cannot prevail while Balder lives, but Loki effects his death by treachery, and falls before the vengeance of Odin. Yet the foul deed has doomed the Æsir; and at length three winters with no summer in heaven bring on 'the twilight of the gods.' Sun, moon, and stars vanish, the heavens are riven, earth quakes, and Fenrir, wolf of ruin, rushes loose. Surtr, the primeval god, comes forth in flames, and battle stands on the plain of Vigridr. Freyr falls before Surtr, Thor slays the snake of Midgard, but dies of its venom, and Odin is devoured by Fenrir. All the Æsir fall, the fire of Surtr consumes the universe, and Ragnarök is complete. But at last there shall rise from the sea a new earth, ever green and fair, and the Æsir shall awake to new life and gather all the worthy dead to dwell with them for ever in the hall of Gimli, roofed with gold and fairer than the sun. N. M. bears the stamp of the scenery and the race among which it arose. The stern northern climate with its 'melancholy skies,' the short day and summer, the long night and winter, the Viking life, and death expected every moment on the shore or the ship's deck, were fit conditions for its fostering. Battle is its central idea; the gods are essentially war gods; the warrior's life is extended to Valhalla. It could not have the rich colour of the Greek mythology conceived under a milder and brighter heaven. This

breathes joy in life, that contempt of death; the gods fall in Ragnarök. The Greek could wish for no better world than that he had; the Northman, dissatisfied with the present, figured to himself a better and more glorious, into which he and his gods should be born again. Greek mythology is beautiful in detail. N. M. unfolds itself as a drama, full of action, with the most impressive catastrophe. See Grundtvig, *Nordens Mythologi* (Copenh. 1808 and 1832); Jakob Grimm, *Deutsche Mythologie* (2d ed. Gött. 1843-46); A. Munch, *Normandes Gudelare i Hedenold* (Christiania, 1847); Keyser, *Normandes Religionsforfatning i Hedenommen* (ib., 1847); Petersen, *Nordisk Mythologi* (Copenh. 1849); Thorpe, *N. M.* (Lond. 1851); Mannhardt, *Die Götterwelt der Deutschen und Nordischen Völker* (vol. i. 1860).

North'men, or **Norse'men**, in the Middle Ages, the general European name for the people of Denmark, Norway, and Sweden. Closely akin to the Jutes and Angles, they were a distinct branch of the Teutonic family of the Aryan race. Their early history is traced but dimly in the *Eddas* (q. v.), which describe society as divided into two classes—(1) the *unfree*, and (2) the *odal proprietors*, who had gained individual possession of the lands formerly held by 'village communities' on the 'Mark' system. Feudal aristocracy there was none; the 'things,' or village assemblies, administered the laws enacted at the greater 'things' of tribal states, and over these were constitutional kings, usually elected. The punishment of crime, left to the individual or to his kith and kin, was either by combat or fine assessed by the State. For the religion of the N. see **NORTHERN MYTHOLOGY**. About 800 A.D. a social convulsion took place, through the great chiefs seizing the lands of the lesser, and Europe suffered for the first time from the piratical inroads of the dreaded 'Vikings' (*vic*, 'a bay'). Before Harald Haarfager (q. v.) in Norway and Gorm the Old in Denmark forced under their strong rule the petty princes of those lands, promiscuous piracy was an honourable pursuit, but the new organisation, which enraged the chieftains by the transfer of their fines and taxes to the royal coffers, compelled the Vikings to confine their marauding expeditions to foreign shores. A general exodus of the N. began, and plundering incursions were succeeded by permanent settlements. In England the inroads, beginning in 787, assume this second phase about 855. Northumbria, Mercia, and part of East Anglia were seized by the Danes, and Ælfred was glad to gain respite for Wessex by the peace of Wedmore in 878. They embraced Christianity, and in another c. had become fused in the common mass of Englishmen under Eadgar the Peaceful (958), leaving traces in the names of many places, and in the local peculiarities of the *Danelagu* ('land of Dane law'). For the later conquest by the Danes, see **ENGLAND**. Orkney (q. v.) and Shetland, early a resort of the Vikings, from 875 to 1355 owned allegiance to the Norwegian kings. The latter part of the 8th c. saw the half-decked galleys of the N. among the western isles of Scotland. Celtic legends call them *Fingall* ('the white strangers'), from their complexion, and *Dugall* ('the black strangers'), from the iron mail of their leaders. Intermarriage produced a race called the 'Gall-Gael,' who joined the N. in their plunderings, and sacked Iona in 795. Before 900 a naval empire had been formed, comprising Argyllshire, Man, Anglesen, and the E. coast of Ireland, and held by rulers called the *Hy-Ivar* ('grandsons of Ivar'), who lived now in Dublin, now in Man. At the battles of Tara (980) and Clontarf (1014), the Irish at length broke the power of these *Ostmen* ('Eastmen') as they were called. After the defeat of Magnus of Norway in 1098, the Isles were divided into two parts, the 'Suderics' and the 'Norderics' (whence the name 'Sodor' in the phrase 'Sodor and Man'), S. and N. of Ardnamurchan Point. Argyll and the Isles appear in the 12th c. under a chief named Somarled, and in the 13th, after the battle of Largs (1263), were ceded to Scotland (1266). The N. colonised the Farøe Isles and Iceland (q. v.), and from thence Greenland (q. v.). Burik, a Swede, called in 862 to settle the disputes of the Slavonic tribes, founded in Russia (q. v.) an empire ruled by his descendants till 1598. From the beginning of the 10th c. the Emperors of the East had a bodyguard of N. known as the Varangians (q. v.). In the weakness of the later Karolings, the N. became the scourge of North-West Germany and Northern France, and from 843 to 860 bands of rovers harassed even the coasts of Spain, S. France, and part of Italy. 'Take the map,'

says Sir F. Palgrave, 'and mark with crossed swords the battles fought by the pirates, or where they pillaged, burned, or destroyed; and the valleys and banks of the Elbe, Rhine and Moselle, Scheldt, Meuse, Somme and Seine, Loire, Garonne, and Adour, and all the coasts and coast-lands between estuary and estuary, all the countries between river and streams will appear bristling as with *chevaux de frise*.' Their numerous settlements soon became merged in the people around them. That of Rolf at Rouen alone survived, and became the nucleus of the Dukedom of Normandy (q. v.). It is characteristic of the N. as a race that on adopting Christianity in their new homes they speedily lost their individuality. Yet their old character remained, and the strength of the North, impregnating the culture of the South, produced the chivalrous spirit that is the glory of the Middle Ages, and the enthusiasm for Holy Church, whose offspring was the Crusades. See Depping, *Histoire des Expéditions Maritimes des Normands* (2 vols. Par. 1826); Palgrave, *History of Normandy and England* (2 vols. Lond. 1832); Strinholm, *Vikingstige der Alten Skandinavier, aus dem Schwedischen von Frisch* (Hamb. 1839); Worsaae, *Normandene i England, Skotland og Island* (Eng. transl. 1852); Ferguson, *The N. in Cumberland and Westmoreland* (Lond. 1856); G. W. Dasent, *The N. in Iceland* (in Oxford Essays for 1858); Johnson, *The Normans in Europe* (1877); and *A Collection of Sagas and other Historical Documents Relating to the Settlements and Descents of the N. on the British Isles*, edited for the series of *Chronicles and Memorials*, by Sir George W. Dasent and Gudbrand Vigfusson (in the press, 1877).

North Sea, or **German Ocean** (anc. *Mare Germanicum*), the part of the Atlantic that separates the British Islands from the continent of Europe. It is 700 miles in length from the Straits of Dover to the Shetland Isles, and 420 in greatest breadth from E. to W., covering an area of some 140,000 sq. miles. Its depth, which on an average is 31 fathoms, increases from S. to N., varying from 9 to 500 feet. By the Skagerrack and its extensions it communicates with the Baltic Sea. From the Continent it receives the waters of the Elbe, Weser, Rhine, and Scheldt, and from Great Britain those of the Thames, Ouse, Humber, Tees, Tyne, Tweed, Forth, Tay, Dee, and Spey. The bed of the sea is traversed by several extensive shoals, of which the chief, the Dogger Bank (q. v.), occupies the centre from lat. 54° 10' to 57° 24' N., and long. 1° to 6° 7' E. The shores of Scandinavia and the N. of Scotland only are bold and rocky. Heligoland is the sole island which properly belongs to the N. S., the islands that fringe the shores of Norway, Denmark, and Holland being rather fragments of the crumbling coast-line. The fisheries of cod, mackerel, herring, &c., are very valuable. Though fraught with the dangers of fog, current, sandbank, and shelving coast, the N. S. is one of the most crowded of all ocean highways. It has been to the hardy northern nations the cradle of seacraft, as was the Mediterranean to the ancients.

Northumberland, a county in the extreme N. of England, bounded N. by the Tweed, E. by the North Sea, S. by Durham, and W. by Cumberland, has an area of 1,290,312 statute acres, and a pop. (1871) of 386,646. The surface is rugged, rising gradually from the coast towards the Cheviot Hills on the Scotch Border; the hill slopes in the centre of the county being clothed with green turf, but those on the Borders with moss and heather. Along the coast lie the Fern, Coquet, and Holy Islands. The most prominent geological feature of N. is the immense coal formation, in some places 1600 feet thick, yielding 20,000,000 tons a year, which runs northward from the Tyne to the river Alne, and of which Newcastle is the centre. The rest of the county is mainly composed of various kinds of sandstone, except the Cheviots, which consist chiefly of porphyry, trap, and limestone. In the E. the soil is a clayey or gravelly loam, in the centre and S. E. the loam rests on a clay subsoil, while towards the Scotch Border there are about 450,000 acres of peat and moorland. The chief rivers are the Tweed, Alne, Coquet, Wansbeck, and Tyne. In 1876 there were 122,006 acres under corn crops, 60,936 under green crops, 95,256 under clover, sanfoin, and grasses in rotation, and 386,797 in permanent pasture; also 18,459 horses, 93,348 cattle, 902,616 sheep, and 13,688 pigs. Cheviot sheep and short-horned Durham cattle are extensively bred; and at Chillingham Castle, near Morpeth, are wild cattle, cream coloured with black muzzles. Coal and lead are the chief mineral products. The first coal-pit was worked at Newcastle in 1240. Along the Tyne there

are glass, iron, lead, and chemical works; manufactories of gloves at Hexham, potteries, brickfields, &c. The principal towns are Newcastle, the capital, Tynemouth, N. Shields, Morpeth, and Alnwick. N. is traversed by the North-Eastern, the Newcastle and Carlisle, and the Border Counties Railways. It returns four members to Parliament. Agricola was the first Roman general who penetrated as far north as N. In 80 A.D. he constructed a line of 18 forts, stretching from the Solway Firth to the mouth of the Tyne. Besides the wall and paved way connecting these forts, two Roman roads, the Maiden Way and Watling Street, traversed N., the former passing from Alstone to Cærvoran, the latter entering the county at Elcheater, and leading over the Cheviots into Scotland. The first English settlement was made in 547 by Ida, who founded the kingdom of the *Northanhymbre* ('the men north of the Humber'); but this included far more than the present N. (See *NORTHUMBRIA*.) Many battles have been fought in N., including the two before Alnwick in 1093 (when Malcolm Canmore was slain) and 1174 (when William the Lion was taken prisoner), that of Otterburn in 1388 (in which 'a dead Douglas victory won'), and that of Flodden, where the Earl of Surrey defeated and slew James IV. in 1513. N. has many antiquities, among which are ancient British remains at Ilderton and near Wooler; also numerous traces of Roman camps and ruins of Border castles.

Northumberland, John Dudley, Duke of, born in 1502, was the son of Henry VII.'s infamous minister, Edmund Dudley (beheaded 1510). Restored in blood (1511), and introduced at court (1523), he was knighted for gallantry in Brandon's French expedition (1522), attended Wolsey on his Paris embassy (1528), and next attached himself to Cromwell. Henry VIII. created him Viscount Lisle (1542), a knight of the garter, and lord high admiral for life, and appointed him by his will a member of the Council of Regency. Earl of Warwick (1547) and chamberlain of England, Dudley distinguished himself at Pinkie, suppressed Kett's rebellion with ruthless severity (1549), and, having wrought the fall of his rival Seymour (q. v.), became earl-marshal, lord-warden of the Northern marches, and Duke of Northumberland (1551), while carrying on the Protestant reign of terror with incensed vigour. Edward's waning health suggested the 'plan' of alienating the succession to Lady Jane Grey (q. v.), who married N.'s fourth son two months before the king's death. After proclaiming her in London, N. marched against Mary's Suffolk forces. But his army melted away, and at Cambridge he too threw up his cap for Queen Mary, and the next day was arrested and brought to London. He died on the scaffold, August 22, 1553, after a shameful apostasy from the faith for which he had plunged England in bloodshed. See *Froude's History of England* (vols. v. and vi.).

Northumberland, Earls of. See *PERCY*.

Northumbria, one of the Old English kingdoms, was founded in 547 A.D. by Ida the Angle. It extended from the Humber to the Forth, and from the North Sea inland to the eastern offsets of the Pennine Range. Its western limit in the country now called Scotland is more uncertain, but would probably be fairly represented by a line drawn from the Liddel through Selkirk or Peebles to the neighbourhood of Stirling. N. was sometimes divided into two kingdoms—*Deira* in the south, corresponding to the modern Yorkshire and Durham; and *Bernicia*, embracing the whole S.E. of Scotland and the modern Northumberland. In the reign of Eadwine (Edwin), who ascended the throne in 617, N. was converted to Christianity; and under him and his successors, it held the foremost place among the English states. It was the seat of the earliest English literature. Here Cædmon (q. v.) in the 7th century composed his sacred paraphrases; and here Bede (q. v.) in the 8th began the still unfinished work of translating the Scriptures into English. But for the destructive ravages of the Danes, who pillaged and burnt its monasteries, N. might perhaps have maintained its intellectual supremacy, and its dialect have become the classic tongue of the whole nation, instead of sinking into a rude though racy patois. Only in the poetry of the Scottish Lowlands—in Dunbar and Lyndsay and Burns—has the speech of Cædmon displayed in later times its ancient dignity and power. See *Freeman's Norman Conquest* (vol. i.).

North-Western Provinces, The, a part of British India, under a lieutenant-governor, and occupying roughly the ancient

kingdom of Hindustan proper. It extends in a semi-circular strip from the mountains of Kumaon in the N.W. in a S.E. direction, including the Doab or tract between the Ganges and Jumna rivers, and then turns again N. to meet the *terai* of Nepaul at its S.E. limit, entirely surrounding on all sides but the N. the province of Oude. (Since the beginning of 1877 Oude has been placed under the lieutenant-governor of the N. W. P.) On the W. it is bounded by the Punjab, S. by the native states of Central India, and E. by the Behar province of Bengal. The seat of government is at Allahabad (q. v.). Total area, 81,403 sq. miles; pop. (1872) 30,781,204. There are also in political connection certain feudatory states, of which the principal are Rampur and Tehri Gurhwal, with an additional area of 6311 sq. miles and a pop. of 1,091,810. In Kumaon there are peaks of the Himalayas reaching an elevation—e.g., Nundi Debi—of 25,000 feet; and in the S. the land rises towards the central Vindhyan range. The rest is almost unbroken plain. The rivers are the Ganges and its tributaries—the Jumna, Ramgunga, Gumti, and Gogra. Except in the submontane *terai*, and the over-irrigated and malarious districts of Seharanpore and Muzaffernuggur, the climate is healthy; the rainfall varies from 30 to 45 inches. The prevailing diseases are fever, bowel complaints, smallpox, and cholera. The staple crops are wheat, barley, rice, Indian-corn, and the millets *jowar* and *bajra*; oilseeds, cotton, sugar-cane, opium, tobacco, indigo, safflower, and potatoes are also largely cultivated. The mhowa and mango trees contribute to the food supply. In the districts of Kumaon and Dehra Dun, about 3000 acres are planted with tea, producing in 1875 about 14 million lbs., mostly of the green sort, for the markets of Central Asia. The total cultivated area is 42,173 sq. miles, or 52 per cent. of the whole. The settlement of land revenue is a temporary one, fixed for a term of 30 years, and made, after measurement, with the owners of the several villages, whether they are the cultivators themselves or landlords. The rate of assessment is 3s. 6d. per acre. Irrigation is carried on from the rivers, wells, and the numerous large *heels* and marshes. The chief Government works are the Ganges and E. Jumna Canals. Up to 1875, a total of £4,535,000 had been spent, and 1,142,000 acres were irrigated; the net returns were £227,000, or 6½ per cent. on capital. There are good central communications, both by road, river, and railway. The East Indian Railway runs through from Ghazipur to Delhi, connecting at Allahabad with the Great Indian Peninsula line, at Ghazilabad with the Punjab line, and at Agra with the new Rajputana line—all on the S. There are also three junctions on the N. with the Oude and Rohilcund Railway. The trade is confined to the export of agricultural produce, principally grain, and of lac dye and saltpetre; in exchange are imported metals, piece goods, salt, spices, and European wares. In 1876-77 the exports to Bengal were valued at £5,034,000, chiefly sugar, indigo, wheat, oil-seeds, and raw cotton; the imports at £3,180,000, including piece-goods to the value of 2½ millions sterling. The only important manufactures are those of leather at Cawnpore, and kincobs, shawls, and gold embroidery at Benares. Weaving and pottery and the making of brass utensils are carried on everywhere. The towns of over 50,000 inhabitants, each with a considerable trade, are Benares, Agra, Allahabad, Cawnpore, Bareilly, Meerut, Furruckabad, Shah-jehanpore, Mirzapore, Moradabad, Muttra, Allyghur, Goruckpore. Benares is the religious and educational, Cawnpore the commercial and military centre; while Agra was the political capital, both under some of the Mogul emperors and in the early days of British rule. Of the total population, the Hindus form as much as 86 per cent., and the Mohammedans only 13 per cent., being most numerous in the Divisions of Rohilcund and Meerut. Of the Hindus, 3,234,000 are Brahmins and 2,395,000 are Rajputs. The average density of the population is 378 per square mile. The condition of the poor is not favourable. Wages have hardly advanced since the beginning of this century. They are usually paid in kind, consisting of about 40 ounces daily of *behjur*, a compound of barley and peas. Salt is a luxury to be tasted only two or three times a week. Many live wholly on *khesaree*, a most unwholesome variety of pulse. The languages spoken are Hindi and Hindustani.

The N. W. Provinces are divided into 7 Divisions and 35 Districts. Two of these Divisions, Kumaon and Jhansi, are 'Non-Regulation.' In 1874-75 the revenue was £5,602,000, of which £4,259,000 came from the land; the local expenditure was

£2,007,000. The police force numbered 25,690 officers and men, maintained at a cost of £321,000. There were altogether 10,205 educational institutions, attended by 261,682 pupils, at a cost of £189,000. There are four Government colleges, of which that at Benares, founded in 1792, is attended by 600 pupils, of whom 280 are in the Sanskrit Department. The European troops in garrison are usually about 6000 strong, chiefly stationed at Agra, Cawnpore, Allahabad, Bareilly, and Meerut; the native sepoy number as many more.

The early history of the N. W. Provinces is that of Hindustan proper. In 1775 the S.E. portion was acquired by the British from the Nawaub Vizier of Oude. In 1801 a further tract was ceded by him; and in 1803 the conquests of Lord Lake extended the frontier as far as Delhi. The hill districts were taken from the Nepaulese in 1815, and the S. Division of Jhansi has been acquired by lapse or forfeiture since 1840. In 1833 the N. W. P. were erected into an independent presidency, called Agra, having previously been known as the Ceded and Conquered Provinces. Sir C. (Lord) Metcalfe was the first governor; but in 1835 the title was changed to that of lieutenant-governor, and the province was subordinated to the Governor-General of India. The revenue and education system was mainly founded by Mr. Thomason, lieutenant-governor from 1843 to 1853. There have been two severe famines—in 1837–38 and again in 1860–61. This tract formed the centre of the Sepoy Mutiny of 1857. The first outbreak was at Meerut; Cawnpore and Jhansi were the scenes of the cruellest massacres; and the native pop., chiefly in Rohilkund and Bundelcund, sided generally with the rebels. But Allahabad was firmly held, as also was Agra, though closely besieged; and, after the capture of Delhi, the British civil administration, after many months of dispossession, gradually reasserted itself throughout the country. As the result, the Central Provinces were formed into a separate government, partly out of the S. districts; Delhi with the surrounding country was permanently attached to the Punjab; and Allahabad was substituted for Agra as the seat of government, as having the more important military and commercial position. See *Annual Blue Books on the Moral and Material Progress of India* (Lond.); *Annual Reports on the Administration of the North-Western Provinces* (Allahabad); Sir J. W. Kaye's *History of the Sepoy War* (2 vols. 1865–70).

Norton, Andrews, an American theologian, was born at Hingham, Massachusetts, December 31, 1786, graduated at Harvard, where he became librarian and lecturer on Biblical Criticism in 1813, and was appointed Dexter Professor of Sacred Literature in 1819. His connection with Harvard terminated in 1830 on account of feeble health. N. died at Newport, Rhode Island, September 18, 1853. He published a *Statement of Reasons for not Believing in the Doctrines of Trinitarianism* (1837, new edition, with Memoir by Dr. Newell, 1856); *The Genuineness of the Gospels* (4 vols. 1837, &c., abridged edition 1867); *Translation of the Gospels* (posthumous, 1855). An opponent alike of John Calvin and Theodore Parker, his position has been thus happily defined, 'N. was radical as a critic and interpreter, and conservative as an expositor of Christian doctrine.'

Norton, The Hon. Caroline Elizabeth (Lady Stirling-Maxwell), daughter of Mr. Thomas Sheridan, and granddaughter of the brilliant author of the *School for Scandal*, was born about 1808. She married the Hon. G. C. Norton in 1827, but the union proving unfortunate, a separation took place in 1836. Mr. Norton died in February 1875. A few months before her death, which took place 15th June 1877, she married Sir William Stirling-Maxwell, Bart., M.P. Her vivid, eloquent, musical genius, in which tones of tender and loving sadness predominated, found expression in the *Sorrow of Rosalie* (1829), *The Undying One* (1831), *The Dream* (1840), *The Child of the Island* (1845), *Aunt Carry's Ballads* (1847), *The Lady of La Garaye* (1862). Her letter to the Queen on Lord Cranworth's Marriage and Divorce Bill (1858) was an impassioned exposition of the social anomalies of women. She also contributed largely to periodical literature, and was author of the following fine novels:—*Stuart of Dunleath* (1851), *Lost and Saved* (1863), and *Old Sir Douglas* (1867).

Norton, Thomas, was born at Sharpenhoe, Bedfordshire, 1532. In his youth he served the Protector Somerset, and in 1555 he entered the Inner Temple as a student. In 1561 he published a translation of Calvin's *Institutes*, which speedily

went through five editions. In the same year he joined Sackville in the production of the first English tragedy, *Gorboduc*, first called *Ferrex and Porrex*, writing the first three acts. He also translated twenty-seven of the Psalms in the Sternhold and Hopkins version, and wrote some controversial tracts. N. died about 1584.

Norwalk, a town of Connecticut, U.S., on Long Island Sound, 42 miles N.E. of New York by rail. Its harbour is good, and its iron-works and lock-works are among the most extensive in the country. It has an active oyster-trade, and supplies New York plentifully with winter flowers. It is besides a convenient summer abode for city merchants. Pop. (1870) 12,119.

Norway (Norw. and Dan. *Norge*, Swed. *Norrige*, 'north kingdom'), a kingdom of Northern Europe, occupying the W. part of the Scandinavian peninsula, is bounded N. by the Arctic Ocean, W. by the Arctic and Atlantic Oceans and the North Sea, S. by the Skagerak, and E. by Sweden and Russia. It is a long and comparatively narrow coast-land, its length in a straight line from Lindesnæs to Nordcap (q. v.) being 1100 miles, while its greatest breadth is 275 and its least 25 miles. In the following table are given the area and population of the twenty *amter*, or counties, into which N. is divided, according to the last census (31st December 1875):—

Amter.	Area in Eng. sq. miles.	Pop. in 1875.
Smaalenene	1,548	107,872
Akershus	1,986	116,117
Christiania (town)	2	76,327
Hedemarken	10,034	120,651
Christian	9,670	115,803
Buskerud	5,659	102,155
Jarlsberg and Laurvik	861	87,494
Bratsberg	5,707	83,186
Nedenæs	3,855	73,571
Lister and Mandal	2,423	75,170
Stavanger	3,421	111,017
Søndre Bergenhus	5,854	119,313
Bergen (town)	1	33,885
Nordre Bergenhus	7,045	86,205
Romsdal	5,650	117,234
Søndre Thronhjelm	7,084	116,841
Nordre Thronhjelm	8,794	82,493
Nordland	14,660	104,195
Tromsø	9,720	54,015
Finmark	18,306	24,071
Total	122,280	1,807,555

There is another division into six *stifter* ('dioceses'). N. is thus the most thinly peopled country of Europe, having only sixteen inhabitants to the square mile.

Natural Features.—Generally speaking, Norway is a part of the great Scandinavian Plateau, which not only includes the Scandinavian peninsula, but also the two adjacent peninsulas of Lapland and Finland. This extensive region is bounded on the E. by the White Sea, the great lakes of Onega and Ladoga, and the Gulf of Finland, and is everywhere furrowed in the interior with valleys, lakes, and streams, while on the coast it is split up by numberless branching *fjorde* ('firths'), through which the sea penetrates far inland, often to the very spurs of *fjelde* ('fells'). The chief inlets are Christiania Fjord, on the S. coast; Flekke, Bukke, Hardanger, Sogne, and Indvig Fjords, on the W.; Molde, Thronhjelm, Falden, Ranen, Salten, Vest, Kyenanger, and Alten Fjords on the N.W., and on the N., Porsanger, Laxe, Tana, and Varanger Fjords. But as these clefts occupy only a minor portion of the surface, N. may be represented as a mass of rock-terraces and inclined planes placed at various heights above the sea. Geographers have divided this mass into three great sections:—Kjølen, Dovre, and Langfeldene. The first includes all the N., has summits reaching 6000 ft. high, and comes as far S. as Røraas, where it is broken by a wide valley running from W. to E., 2000 feet above the sea. Westward from the Røraas district to the river Rauma stretches the Dovre Fjeld, a plateau 192 miles in extent, from which rise numerous peaks, the highest being Snehetta, 7333 feet. S. of the Rauma extend Langfeldene ('the long fells'). Among these, between Valdres, Sogn, and Gudbrandsdal, is the grandest region in N., called Jotunheimen ('the Jotuns' home') or Jotunfjelde, forming a plateau at an elevation of 4000 feet, from which rises

the loftiest summit in Scandinavia, Galdhøpiggen (8161 feet). Between Gudbrandsdal and Oesterdal is the Rundane range (highest peak 6730 feet), which, with the Romsdal Alps and the Tromsø Mountains, abounds in the sublimest mountain scenery. The numerous islands (*Skjærgaarden*, 'The Skerry land') surrounding the bold coasts of N. are larger and more rugged than those that skirt the shores of Sweden. Great tracts of N. are covered with perpetual snow and ice. The largest glacier in Europe is the Jostedalbræ (590 sq. miles), in Sogn, Nordfjord, and Søndfjord, the lower edge of which is 4000-4500, and the upper 6495 feet above the sea. Its chief branches are the Boiumsbræ, the Suphellebræ, and the Negaardsbræ, whose lower edge is 1060 feet above the sea level. Beside the Hardanger Fjord lies the great Folgefon glacier (108 sq. miles), whose ridge is 5276 feet above the sea; and from Ranen Fjord up to Beier Fjord within the Arctic Circle stretches (42 miles) the great *névé* of Svartisen (440 sq. miles).

Hydrography.—The chief rivers ('Elve') in the S. of N. are the Glommen (302 miles), the largest stream in Scandinavia, whose tributaries are the Renelv and Vormen (the outlet of Mjösen); the Dramselv (163), with its affluents the Randselv, Bæga (85), and Hallingelv (112); the Skienselv (126); the Nisserelv (112); and Otteren (140), all in South N., and falling into the Skagerak; and in the North the Altenelv (98); Tanaelv (115), formed from the Anarjokka (63), and the Karasjokka (56); and the Pasvikelv (77), discharging Lake Enare. The two last partly separate N. from Russia. N. abounds in long, narrow lakes, which are mostly expansions of rivers. The largest are Mjösen (196 sq. miles), Røsvandet (110), Fæmundsjø, Randsfjord, and Tyrifjord.

Climate.—The entire W. coast of N. enjoys a temperature milder by 36° F. than any other country in the same latitude. A vast chain of banks occupies the space between the shore and the ocean bed, and over this, which presents an impassable barrier to the Polar Sea, flows the warm surface current of the Atlantic. During the greater part of the year the surface of the sea is warmer than the atmosphere. Finmark and the interior of South N. are, however, subject to great extremes of temperature, the difference of which is 45°-54° F. The prevailing winds are in winter land winds blowing from S. to N. or straight out of the fjords, and in summer sea winds from N. to S. The annual rainfall at Christiania averages 21, on Dovre 13, at Bergen 71, and at Lofoten 63 inches. On the island of Seiland in Finmark (70° 30' N. lat.) the snow-line is 2880, in the Alpine region of the Dovrefield (62° 20'), 5200, and on the northern ridges of Jotunheimen 4610 feet high.
